Abstract

In this paper, we examine interlace polynomials of lollipop and tadpole graphs. The lollipop and tadpole graphs are similar in that they both include a path attached to a graph by a single vertex. In this paper we give both explicit and recursive formulas for each graph, which extends the work of Arratia, Bollóbas and Sorkin [4],[5], among others. We also give special values, examine adjacency matrices and behavior of coefficients of these polynomials.

Keywords: graph polynomial, interlace polynomial, lollipop graph
Mathematics Subject Classification: 05C31, 05C50, 11B39
DOI: 10.5614/ejgta.2022.10.1.14

1. Introduction

The interlace polynomial of a graph was introduced by Arratia, Bollóbas, and Sorkin, and it is a polynomial that contains and represents the information gained from performing the toggling process on the graph, see [4]. Interlace polynomials share similarities with other graph polynomials, such as Tutte and Martin polynomials as they are utilized in applications to science and other
fields, [6, 8, 10, 15]. More recently, researchers have studied different types of graph polynomials, such as Hosoya and M-polynomials, which give information about distance-based invariants related to chemical graphs,[1, 12, 9].

Interlace polynomials give important information about the graph, such as, the number of $k$-component circuit partitions, for $k \in \mathbb{N}$. In [5], interlace polynomials for some simple graphs like paths, cycles, and complete graphs are given, although not all of the formulas are easy to use. Li, Wu and Nomani give recursive formulas for interlace polynomials of ladder and $n$-Claw graphs, see [13, 16]. In addition, Eubanks-Turner and Li give recursive and explicit formulas for friendship graphs, see [11]. Also, work has been done in utilizing bivariate and multi-variate interlace polynomials, see [3, 5, 18]. Here, we focus our attention on establishing the interlace polynomials of lollipop and tadpole graphs. Both graphs have the structure that each has a well-known subgraph which is connected to a path by a single vertex.

A lollipop graph is a simple graph that consists of a complete graph being joined to a path with a bridge. Lollipop graphs have applications to stochastic processes and spectral graph theory [14, 19]. In particular, lollipop graphs have maximum possible hitting time, cover time and commute time [17]. In this work we consider the interlace polynomial of the lollipop graph. We give both the recursive and explicit formulas for the interlace polynomials of lollipop graphs. As Eubanks-Turner and Li did in [11], we consider natural questions regarding interlace polynomials of the lollipop graph, such as:

1. What are the general forms of the coefficients of the interlace polynomial of a lollipop graph?
2. What are the evaluations of the interlace polynomial of a lollipop graph at certain values and what does it describe about related graph properties?

We further consider graphs related to lollipop graphs called tadpole graphs. Tadpole graphs are simple graphs obtained by joining a cycle to a path via a bridge, [9]. Although the recursive and explicit formulas for interlace polynomials of tadpole graphs are given in [2], we give a different explicit formula and further results about interlace polynomials of tadpole graphs related to the latter mentioned questions.

For a simple graph $G$, to construct the interlace polynomial we first need the following definition. Note, $\forall a \in V(G), N(a) = \{\text{neighbors of } a\}$.

**Definition 1.1. (Pivot)** Let $G = (V(G), E(G))$ be any undirected graph without a loop and $a, b \in V(G)$ with $ab \in E(G)$. We first partition the neighbors of $a$ or $b$ into three classes:

1. $N(a) \setminus (\{b\} \cup N(b))$;
2. $N(b) \setminus (\{a\} \cup N(a))$;
3. $N(a) \cap N(b)$.

The pivot graph $G_{ab}$ of $G$, with respect to $ab$ is the resulting graph of the toggling process: $\forall u, v \in V(G)$, if $u, v$ are from different classes shown above, then $uv \in E(G) \iff uv \notin E(G_{ab})$.

Note that $G_{ab} = G_{ba}$. The pivot operation is only defined for an edge of $G$. The definition for the interlace polynomial of a simple graph $G$ is given below. Here, $\forall u \in V(G), G - u$ is the graph resulting from removing $u$ and all the edges of $G$ incident to $u$ from $G$. 

www.ejgta.org
Definition 1.2. Let $\mathcal{G}$ be the class of finite undirected graphs having no loops nor multiple edges. There is a unique map $q : \mathcal{G} \rightarrow \mathbb{Z}[x]$, such that, $G \mapsto q(G)$. For any undirected graph $G$ with $n$ vertices that has no loops nor multiple edges, the interlace polynomial $q(G)$ of $G$ is defined by

$$q(G) = \begin{cases} x^n, & \text{if } E(G) = \emptyset, \\ q(G - a) + q(G^{ab} - b), & \text{if } ab \in E(G). \end{cases}$$

This map is a well-defined polynomial on all simple graphs, see [2]. Next, we give some known results about interlace polynomials and results relating the interlace polynomials to structural components of graphs.

Lemma 1.1. [5] Given the interlace polynomial $q(G)$ of any undirected graph $G$, the following results hold:

1. The interlace polynomial of any simple graph has zero constant term.
2. For any two disjoint graphs $G_1$, $G_2$, we have $q(G_1 \cup G_2) = q(G_1) \cdot q(G_2)$.
3. The degree of the lowest-degree term of $q(G)$ is $k(G)$, the number of components of $G$.
4. $\deg(q(G)) \geq \alpha(G)$, where $\alpha(G)$ is the independence number, i.e., the size of a maximum independent set.
5. Let $\mu(G)$ denote the size of a maximum matching (maximum set of independent edges) in a graph $G$. If $G$ is a forest with $n$ vertices, then $\deg(q(G)) = n - \mu(G)$.

Lemma 1.2. [5] The interlace polynomials for the following graphs are as follows:

1. (complete graph $K_m$) $q(K_m) = 2^{m-1}x$;
2. (complete bipartite graph $K_{mn}$) $q(K_{mn}) = (1 + x + \ldots + x^{m-1})(1 + x + \ldots + x^{n-1}) + x^m + x^n - 1$;
3. (path $P_n$ with $n$ edges) $q(P_1) = 2x$, $q(P_2) = x^2 + 2x$, and for $n \geq 3$, $q(P_n) = q(P_{n-1}) + xq(P_{n-2})$;
4. (small cycles $C_m$) $q(C_3) = 4x$ and $q(C_4) = 2x + 3x^2$.

Definition 1.3. Let $m, n \in \mathbb{N}$, with $m \geq 3$, $n \geq 0$. The lollipop graph $L_{m,n}$ is the simple graph obtained by joining a complete graph $K_m$ to a path graph $P_n$ at one of the vertices of $K_m$. The lollipop graph $L_{m,n}$ has $m + n$ vertices and $\binom{m}{2} + n$ edges. Note, we hold $m \geq 3$ to disregard the case when $L_{m,n}$ is a path.

2. Interlace Polynomial of Lollipop Graphs

Next, we develop interlace polynomials of lollipop graphs $L_{m,n}$, where $m, n \in \mathbb{N}$. We treat $L_{m,0}$ as the complete graph with $m$ vertices. The lollipop graph has the same recursive formula as the path graph, see Lemma 1.2 (3).
Let $m \geq 3$. For $n \geq 2$, $q(L_{m,n}) = q(L_{m,n-1}) + xq(L_{m,n-2})$, where $q(L_{m,0}) = q(K_m)$ and $q(L_{m,1}) = q(K_m) + xq(K_{m-1})$.

**Proof.** Clearly, $q(L_{m,0}) = q(K_m)$. Also, $L_{m,1}$ is a graph consisting of a complete graph with $m$ vertices and a path of length one. Labeling the edge of the path as $ab$, where $\deg(a) = 1$, we have, $q(L_{m,1} - a) = q(K_m)$. Also note that $L_{m,1} - b = K_{m-1} \cup \{a\}$, where $b \in V(K_m)$. So, $q(L_{m,1}) = q(K_m) + x \cdot q(K_{m-1})$, by Lemma 1.2 (2).

Now assume $n \geq 2$ and consider the graph $L_{m,n}$ with the edge $ab$, such that $\deg(a) = 1$. See the following figure:

Considering the interlace polynomial, we have that $L_{m,n} - a = L_{m,n-1}$.
Hence, $q(L_{m,n}) = q(L_{m,n-1}) + xq(L_{m,n-2})$, for $n \geq 2$ as desired.

The next result gives the explicit formula for the interlace polynomial of $L_{m,n}$ for $m \geq 3$ and $n \geq 0$.

**Theorem 2.1.** For $m \geq 3$ and $n \geq 0$,

$$q(L_{m,n}) = \frac{1}{\sqrt{1 + 4x}} \left[ \frac{q(K_m) + \gamma xq(K_{m-1})}{\gamma^{n+1}} - \frac{(q(K_m) + \beta xq(K_{m-1}))}{\beta^{n+1}} \right]$$

where $\gamma = \frac{\sqrt{1+4x} - 1}{2x}$ and $\beta = \frac{-\sqrt{1+4x} - 1}{2x}$.

**Proof.** We utilize the recurrence relation in a generating function $G(y)$, where the coefficient of $y^n$ is $q(L_{m,n})$:

$$G(y) = \sum_{n=0}^{\infty} q(L_{m,n})y^n$$

By Lemma 2.1,

$$G(y) = q(L_{m,0}) + y \cdot q(L_{m,1}) + \sum_{n=2}^{\infty} (q(L_{m,n-1}) + xq(L_{m,n-2})) y^n$$

$$= \frac{q(L_{m,0}) + y \cdot q(L_{m,1}) - y \cdot q(L_{m,0})}{1 - y - xy^2}$$

For convenience, let $\gamma = \frac{\sqrt{1+4x} - 1}{2x}$ and $\beta = \frac{-\sqrt{1+4x} - 1}{2x}$, the roots of the polynomial $1 - y - xy^2$. Since $q(L_{m,0}) = q(K_m)$ and $q(L_{m,1}) = q(K_m) + xq(K_{m-1})$, we have the desired result.

**Proposition 2.1.** For $m \geq 3$, $n \geq 0$, $\deg(q(L_{m,n})) = 1 + \left\lceil \frac{n}{2} \right\rceil$, where $1 + \left\lceil \frac{n}{2} \right\rceil = \alpha(L_{m,n})$, the independence number of $L_{m,n}$. 

---

Figure 4. $L_{m,n}^{ab} - b$. 

---
Proof. The maximal independent set of vertices consists of the leaf, alternating non-adjacent vertices of the path, and potentially one vertex in the complete component of the graph. For even path length \((n \text{ odd})\), this set is of size \(1 + \frac{n+1}{2}\). For odd path length \((n \text{ even})\), it is size \(1 + \frac{n}{2}\). Including any additional vertex of the graph would result in a dependent vertex set. Therefore we have the desired result.

For paths of odd length, there are an even number of vertices, and at most \(\frac{n+1}{2}\) independent vertices. For paths of even length, there are an odd number of vertices, and at most \(\frac{n}{2}\) independent vertices. We have that \(\deg(q(L_{m,n})) = 1 + \left\lceil \frac{n}{2} \right\rceil\) by strong induction.

Arritia, Böllöbas and Sorkin evaluate interlace polynomials at certain small values of \(x\), as these values give information relating to circuit partitions of the graphs, see [5]. They show that for any graph \(G\), \(q(G)(2) = 2^{|V(G)|}\) and if \(H\) is the interlace graph of an Euler circuit of a 2-in, 2-out digraph \(D\), then \(q(H)(1)\) is the number of Euler circuits of \(D\).

We now give some propositions which show the evaluations of the lollipop graph at 1 and \(-1\).

**Corollary 2.1.** [5] For the path \(P_n\), \(q(P_n)(1) = F_{n+2}\), the \((n + 2)\)’nd Fibonacci number (with \(F_0 = 0\) and \(F_1 = 1\)).

Since the lollipop has the same recursive formula as the path, we obtain similar results when evaluating at \(x = 1\). For the evaluation at \(x = -1\), we give our results in the same form as what was given in [2].

**Proposition 2.2.** For \(m \geq 3, n \geq 0\),

1. \(q(L_{m,n})(1) = 2^{m-2}F_{n+3}\), the \((n + 2)\)’nd Fibonacci number (with \(F_0 = 0\) and \(F_1 = 1\)).

2. \(q(L_{m,n})(-1) = \begin{cases} 
-2^{m-1}, & \text{if } n \equiv 0 \mod 6, \\
-2^{m-2}, & \text{if } n \equiv 1, 5 \mod 6, \\
2^{m-2}, & \text{if } n \equiv 2, 4 \mod 6, \\
2^{m-1}, & \text{if } n \equiv 3 \mod 6.
\end{cases}\)

**Proof.** We prove (1) by strong induction on \(n\). Note, \(q(L_{m,0})(1) = q(K_m)(1) = 2^{m-1} = 2^{m-2}F_3\), by Lemma 1.2 (1). Let \(n \geq 1\) and assume \(q(L_{m,n})(1) = 2^{m-2}(F_{k+3})\), for all \(k, 0 \leq k \leq n\). By Lemma 2.1,

\[
q(L_{m,n+1})(1) = q(L_{m,n})(1) + q(L_{m,n-1})(1) \\
= 2^{m-2}(F_{n+3}) + 2^{m-2}(F_{n+2}) \\
= 2^{m-2}(F_{n+3} + F_{n+2}) \\
= 2^{m-2}(F_{n+4}), \text{ by definition of the Fibonacci sequence,} \\
= 2^{m-2}(F_{(n+1)+3}).
\]
For (2), also by Lemma 2.1,

\[
q(L_{m,n})(-1) = q(L_{m,n-1})(-1) - q(L_{m,n-2})(-1) \\
= [q(L_{m,n-2})(-1) - q(L_{m,n-3})(-1)] - q(L_{m,n-2})(-1) \\
= -q(L_{m,n-3})(-1) \\
= -q(L_{m,n-4})(-1) + q(L_{m,n-5})(-1) \\
= -q(L_{m,n-5})(-1) + q(L_{m,n-6})(-1) + q(L_{m,n-5})(-1) \\
= q(L_{m,n-6})(-1).
\]

Therefore, \(q(L_{m,n})(-1)\) is periodic of period 6. The first six values of \(q(L_{m,n})(-1)\) are: \(q(L_{m,0})(-1) = -2^{m-1}\), \(q(L_{m,1})(-1) = -2^{m-2} = q(L_{m,5})(-1)\), \(q(L_{m,2})(-1) = 2^{m-2} = q(L_{m,4})(-1)\), \(q(L_{m,3})(-1) = 2^{m-1}\).

\[\square\]

In the following Theorem Balister, Bollóbas, Cutler and Pebody give an explicit formula for the interlace at \(x = -1\), therefore proving the conjecture in [7].

**Theorem 2.2.** [7] Let \(A\) be the adjacency matrix of \(G\), \(n = |V(G)|\) and let \(r = \text{rank}(A + I)\) over \(\mathbb{Z}_2\) and \(I\) be the \(n \times n\) identity matrix. Then

\[
q(G, -1) = (-1)^n(-2)^{n-r}.
\]

Now we consider applications of lollipop graphs in solving a linear algebra problem. We determine the ranks of the adjacency matrices related to \(L_{m,n}\) over \(\mathbb{Z}_2\). For \(m \geq 3\), \(n \geq 0\), let \(A_{m,n}\) denote the adjacency matrix of \(L_{m,n}\). Then \(A_{m,n}\) has the form

\[
A_{m,n} =
\begin{pmatrix}
0 & 1 & \ldots & 1 & | & 0 & \ldots & 0 \\
1 & 0 & 1 & : & | & : \\
0 & : & & & | & & \\
\vdots & & & & | & & \\
0 & & & & | & & \\
1 & \ldots & 1 & 0 & | & 1 & 0 & \ldots & 0 \\
\vdots & & & & | & & \\
0 & \ldots & 0 & 1 & | & & \\
\vdots & & & & | & & \\
0 & 0 & 0 & | & A
\end{pmatrix}_{(m+n) \times (m+n)}
\]

with \(A_{m \times n} = [a_{ij}]\), where

\[
a_{ij} = \begin{cases} 
1, & \text{if } j = i + 1 \text{ or } j = i - 1, \\
0, & \text{otherwise}. 
\end{cases}
\]
Proposition 2.3. Suppose $m \geq 3$, $n \geq 0$, let $C_{m,n} = A_{m,n} + I_{m+n}$, where $I_{m+n}$ is the $(m + n) \times (m + n)$ identity matrix. Then, $\text{rank}(C_{m,n}) = \begin{cases} n + 1, & \text{if } n \equiv 0, 3 \pmod{6}, \\ n + 2, & \text{otherwise.} \end{cases}$

Proof. Using Theorem 2.2 and Proposition 2.2(2), we have the desired result. \qed

We end this section by giving information about coefficients of $L_{m,n}$, which gives us a way to describe the relations between coefficients.

Theorem 2.3. For $m \geq 3, n \geq 0$, write $q(L_{m,n})(x) = \sum_{k=0}^{1+\left\lceil \frac{n}{2} \right\rceil} l_{m,n,k} x^k$. Then the coefficients $l_{m,n,k} = 2^{m-2} \left( \binom{n-k+1}{k-2} + 2 \binom{n-k+1}{k-1} \right)$ for all $k \geq 0$.

Proof. Note that from Lemma 2.1, we have, $q(L_{m,n}) = q(L_{m,n-1}) + xq(L_{m,n-2})$, which yields

$$l_{m,n,k} = l_{m,n-1,k} + l_{m,n-2,k-1}.$$ (1)

Fix $m \geq 3$. We proceed by multivariate strong induction on $n$ and $k$. To show the base cases, note that by Lemma 1.1 (1), $l_{m,n,0} = 0$, for all $n \geq 0$ and so $l_{m,n,0} = 2^{m-2} \left( \binom{n+1}{-2} + 2 \binom{n+1}{-1} \right)$, for all $n \geq 0$. By lemma 1.2 (1), $q(L_{m,0}) = q(K_m) = 2^{m-1}x$ and so $l_{m,0,k} = \begin{cases} 0, k \neq 1, \\ 2^{m-1}, k = 1. \end{cases}$

Now fix $n, k \geq 0$. Assume the following inductive hypotheses:

$l_{m,i,j} = 2^{m-2} \left( \binom{i-j+1}{i-2} + 2 \binom{i-j+1}{i-1} \right)$, for all $i, j$, when $1 \leq i \leq n$ and $1 \leq j \leq k + 1$.

$l_{m,i,j} = 2^{m-2} \left( \binom{i-j+1}{j-2} + 2 \binom{i-j+1}{j-1} \right)$, for all $i, j$, when $1 \leq i \leq n + 1$ and $1 \leq j \leq k$.

Consider $l_{m,n+1,k+1}$. From Equation (1), we have, $l_{m,n+1,k+1} = l_{m,n,k+1} + l_{m,n-1,k-1}$. By the first inductive hypothesis,

$$l_{m,n,k+1} = 2^{m-2} \left( \binom{n-(k+1)+1}{k+1-2} + 2 \binom{n-(k+1)+1}{k+1-1} \right) = 2^{m-2} \left( \binom{n-k}{k-1} + 2 \binom{n-k}{k} \right).$$

By the second inductive hypothesis,

$$l_{m,n-1,k} = 2^{m-2} \left( \binom{n-1-k+1}{k-2} + 2 \binom{n-1-k+1}{k-1} \right) = 2^{m-2} \left( \binom{n-k}{k-2} + 2 \binom{n-k}{k-1} \right).$$

Hence,

$$l_{m,n+1,k+1} = l_{m,n,k+1} + l_{m,n-1,k-1} = 2^{m-2} \left( \binom{n-k}{k-1} + \binom{n-k}{k-2} + 2 \binom{n-k}{k} + 2 \binom{n-k}{k-1} \right).$$
Applying Pascal’s Identity yields:

\[ l_{m,n+1,k+1} = 2^{m-2} \left( \binom{n-k}{k-1} + 2 \binom{n-k+1}{k-1} \right) \]

Thus, \( l_{m,n,k} = 2^{m-2} \left( \binom{n-k+1}{k-2} + 2 \binom{n-k+1}{k-1} \right) \) for all \( m \geq 3 \) and \( n,k \geq 0 \).  

3. Interlace Polynomial of Tadpole Graphs

Now we turn our attention to tadpole graphs. Tadpole graphs have structure similar to lollipop graphs as they are cycles connected to a path at a vertex of the cycle.

Definition 3.1. Let \( m,n \in \mathbb{N} \), with \( m \geq 3 \), \( n \geq 0 \). The tadpole graph \( T_{m,n} \) is the simple graph obtained by joining a cycle \( C_m \) to a path graph \( P_n \) at one of the vertices of \( C_m \). The tadpole graph \( T_{m,n} \) has \( m+n \) vertices and \( m+n \) edges. Note, we hold \( m \geq 3 \) to disregard the case when \( T_{m,n} \) is a path.

Next, we show that the recursive formula for the interlace polynomial of the tadpole graph is the same as the interlace polynomial of the path and lollipop graphs. The explicit formula for the interlace polynomial of the tadpole graph has a structure similar to the interlace polynomial of the lollipop graph.  

Lemma 3.1. For \( m \geq 3 \), \( n \geq 2 \), \( q(T_{m,n}) = q(T_{m,n-1}) + xq(T_{m,n-2}) \), where \( q(T_{m,0}) = q(C_m) \) and \( q(T_{m,1}) = q(C_m) + xq(P_{m-2}) \).

We utilize the following explicit formulas given in [5].  

Lemma 3.2. [5] Let \( P_m \) be the path of length \( m \) (with \( m+1 \) vertices and \( m \) edges) and \( C_m \) denote the cycle with \( m \) vertices.

1. For \( m \geq 2 \), the interlace polynomial of the path \( P_m \) satisfies

\[ q(P_m) = \frac{(3+y)(y-1)}{4y} \left( \frac{1+y}{2} \right)^{m+1} + \frac{(3-y)(y+1)}{4y} \left( \frac{1-y}{2} \right)^{m+1} \]

where \( y = \sqrt{1 + 4x} \).
2. For \( m \geq 4 \), with \( y = \sqrt{1 + 4x} \),

\[
q(C_m) = \left(\frac{1 - y}{2}\right)^m + \left(\frac{1 + y}{2}\right)^m + \frac{y^4 - 10y^2 - 7}{16} \quad \text{for } m \text{ even,}
\]

\[
q(C_m) = \left(\frac{1 - y}{2}\right)^m + \left(\frac{1 + y}{2}\right)^m + \frac{y^2 - 5}{4} \quad \text{for } m \text{ odd.}
\]

In [2] a general explicit function for \( q(T_{m,n}) \) is given for \( m \geq 6, n \geq 5 \). Here we provide an alternative form of the explicit function for \( T_{m,n} \) and give results for \( m \geq 3, n \geq 0 \).

**Theorem 3.1.** For \( m \geq 3 \) and \( n \geq 0 \),

\[
q(T_{m,n}) = \frac{q(C_m) + xq(P_{m-2})\gamma \left(\frac{1}{\gamma}\right)^{n+1}}{x(\beta - \gamma)} - \frac{q(C_m) + xq(P_{m-2})\beta \left(\frac{1}{\beta}\right)^{n+1}}{x(\beta - \gamma)}
\]

where \( \gamma = \frac{\sqrt{1 + 4x} - 1}{2x} \), \( \beta = \frac{-\sqrt{1 + 4x} - 1}{2x} \) and \( q(C_m) \) and \( q(P_m) \) are the explicit forms given in Lemma 3.2.

**Proposition 3.1.** For \( m \geq 3, n \geq 1 \), \( \deg(q(T_{m,n})) = 1 + \left\lceil \frac{n}{2} \right\rceil \), when \( n \) is odd and \( \deg(q(T_{m,n})) = 2 + \left\lfloor \frac{n}{2} \right\rfloor \), when \( n \) is even.

**Proof.** Similar to Proposition 2.1. \( \Box \)

**Proposition 3.2.** For \( m \geq 3, n \geq 1 \), the independence number \( \alpha(T_{m,n}) = \left\lceil \frac{n-1}{2} \right\rceil + \left\lfloor \frac{m}{2} \right\rfloor \).

Next, we give evaluations of \( T_{m,n} \) at \( x = 1 \) and \(-1\). Similar to the interlace polynomials of the path and lollipop graphs evaluated at \( x = 1 \), the interlace polynomial for the tadpole graph evaluated at 1 involves the Fibonacci sequence.

**Theorem 3.2.** For \( m \geq 3, n \geq 0 \),

\[
q(T_{m,n})(1) = \begin{cases} 
(F_{n+1}\sqrt{5} + F_n)F_m + 2F_{n+1}\left(\frac{1 - \sqrt{5} - 1}{2}\right)^m, & \text{if } m \text{ is even,} \\
(F_{n+1}\sqrt{5} + F_n)F_m + 2F_{n+1}\left(\frac{1 - \sqrt{5}}{2}\right)^m, & \text{if } m \text{ is odd,}
\end{cases}
\]

where \( F_n \) is the \( n \)-th Fibonacci number with \( F_0 = 0 \) and \( F_1 = 1 \).

**Proof.** Fixing \( m \geq 3 \), this proof follows by induction on \( n \) and Lemma 3.2(2). \( \Box \)

**Proposition 3.3.** For \( m \geq 3, n \geq 0 \), let \( C^m = \left(\frac{1 - \sqrt{3}}{2}\right)^m + \left(\frac{1 + \sqrt{3}}{2}\right)^m \).

We have that \( C^m = \begin{cases} 
2, & \text{if } m \equiv 0 \mod 6, \\
1, & \text{if } m \equiv 1, 5 \mod 6, \\
-1, & \text{if } m \equiv 2, 4 \mod 6, \\
-2, & \text{if } m \equiv 3 \mod 6,
\end{cases} \) and then

222
Interlace polynomials of lollipop and tadpole graphs

\[ q(T_{m,n})(-1) = \begin{cases} 
4, & \text{if } n, m \equiv 0 \mod 6, \\
-1, & \text{if } n \equiv 0 \mod 6; m \equiv 1, 5 \mod 6, \\
1, & \text{if } n \equiv 0 \mod 6; m \equiv 2, 4 \mod 6, \\
-4, & \text{if } n \equiv 0 \mod 6; m \equiv 3 \mod 6, \\
2, & \text{if } n \equiv 1 \mod 6; m \text{ is even}, \\
-2, & \text{if } n \equiv 1 \mod 6; m \text{ is odd}, \\
-C^m, & \text{if } n \equiv 2 \mod 6, \\
-q(T_{m,0}), & \text{if } n \equiv 3 \mod 6, \\
-q(T_{m,1}), & \text{if } n \equiv 4 \mod 6, \\
-q(T_{m,2}), & \text{if } n \equiv 5 \mod 6.
\end{cases} 
\]

**Proof.** For \( m \geq 3 \), we have,

\[
\frac{(1 - \sqrt{-3})^m}{2^m} + \frac{(1 + \sqrt{-3})^m}{2^m} = \frac{1}{2^m} \left( e^{i\frac{m\pi}{3}} + e^{-i\frac{m\pi}{3}} \right) = 2 \cos\frac{m\pi}{3}.
\]

Note, that \( \cos\frac{m\pi}{3} = \begin{cases} 
1, & \text{if } m \equiv 0 \mod 6, \\
\frac{1}{2}, & \text{if } m \equiv 1, 5 \mod 6, \\
-\frac{1}{2}, & \text{if } m \equiv 2, 4 \mod 6, \\
-1, & \text{if } m \equiv 3 \mod 6.
\end{cases} \)

Therefore, \( C^m \) is as claimed. Utilizing Lemma 3.2, the remainder of the proof is similar to Proposition 2.2.

Now we consider applications of tadpole graphs in solving a linear algebra problem. For \( n \geq 1 \),
let $B_{mn}$ denote the adjacency matrix of $T_{mn}$. Then

$$B_{mn} = \begin{pmatrix}
B & \vdots & \vdots & \vdots & \vdots \\
\vdots & \ddots & \ddots & \ddots & \vdots \\
\vdots & \ddots & \ddots & \ddots & \vdots \\
0 & \ldots & 0 & 1 & 0 \\
\vdots & 0 & 0 & \ddots & A \\
0 & 0 & 0 & \ldots & B
\end{pmatrix}_{(m+n) \times (m+n)}$$

with $B_{m \times m} = [b_{ij}]$, where

$$b_{ij} = \begin{cases}
1, & \text{if } j = i + 1 \text{ or } j = i - 1, \\
1, & \text{if } i = 1, j = m \text{ or } i = m, j = 1, \\
0, & \text{otherwise}.
\end{cases}$$

$$A_{n \times n} = [a_{ij}],$$

where

$$a_{ij} = \begin{cases}
1, & \text{if } j = i + 1 \text{ or } j = i - 1, \\
0, & \text{otherwise}.
\end{cases}$$

Proposition 3.4. Suppose $m \geq 3$, $n \geq 0$, let $D_{m,n} = B_{m,n} + I_{m+n}$, where $I_{m+n}$ is the $(m + n) \times (m + n)$ identity matrix. Then,

$$\text{rank}(D_{m,n}) = \begin{cases}
m + n - 2, & \text{if } n, m \equiv 0, 3 \mod 6, \\
m + n, & \text{if } n \equiv 0, 2, 3, 5 \mod 6; m \equiv 1, 2, 4, 5 \mod 6, \\
m + n - 1, & \text{if } n \equiv 1, 4 \mod 6 \text{ and } n \equiv 2, 5 \mod 6; m \equiv 0, 3 \mod 6.
\end{cases}$$

Proof. Using Theorem 2.2 and Lemma 3.3, we have the desired result. \qed
