ABSTRACT: Incidence of uterine anomalies was 3.5-8% of general population. Generally they are asymptomatic; a few may have gynecological symptoms and obstetric morbidities. If detected antenatally, close follow up is warranted till delivery to avoid obstetric morbidities. Surgical intervention in some of the anomalies will certainly help to improve birth rates significantly. We are presenting three different case reports of uterine anomalies detected accidentally during pregnancy and their outcome.

KEYWORDS: Uterus, Anomalies, Bicornuate, Pregnancy.

INTRODUCTION: Uterus develops by the fusion of two mullerian ducts at 6–12 weeks of intrauterine period. Septum present initially between the two mullerian ducts disappears later during the development and forms a single cavity. Disorders of lateral fusion of the mullerian ducts lead to uterine didelphys, septate & bicornuate uterus.

Incidence of uterine anomalies is around 3.5-8% in general population.1 Although some uterine anomalies cause infertility, most of them conceive without difficulty. Incidence of spontaneous abortion, cervical incompetence, PPROM, fetal loss, IUGR, preterm delivery, malpresentation, caesarean section, retained placenta and PPH are all increased when uterine malformation are present.2 By detection of these uterine malformations, we can correct them with recent operating modalities thereby preventing obstetric complications & improving reproductive outcome.

We are presenting three different case reports of uterine anomalies detected accidentally during pregnancy which were admitted and operated at district hospital, Mandya institute of medical sciences, Mandya.

CASE 1: A 27yr old G3P1L1A1 with term gestation with breech presentation was admitted in labor. She had first vaginal delivery with birth weight of 2.5 kg. Clinical examination showed incomplete breech presentation in labor. USG report showed Single live intra uterine gestation with incomplete breech presentation with right sided adnexal mass of 11x8x6cm.

Emergency caesarean section was done in view of fetal distress & a live male baby of weight 2.75kg was delivered. Per operatively bicornuate uterus with well-developed right horn of uterus was noticed (Figure 1A), tubes and ovaries were normal (Figure 1B). Post-operative period was uneventful and patient was discharged on 7th post-operative day.

CASE 2: A primigravida with 36 weeks of gestation with cephalic presentation with PIH was admitted in labor with PROM. On examination her BP was 150/110 mmHg. P/A – uterus 34 weeks size & cephalic presentation. P/V- Cx-30% effaced, os-3cm dilated with vertex at -2 stations. P/S–vertical
septum was seen in the vagina about 2.5" & diagnosed as primigravida with border line preterm gestation with septate vagina in latent phase of labor. As her BP was persistently 150/100mmhg, Tab. Labetalol 100 mg was started & patient was taken for emergency LSCS due to arrest of dilatation. Live male baby of weight 1.8kg was extracted. Per-op findings showed septate uterus with complete septa from fundus to the vagina (Figure 2). Post- op period was uneventful & discharged on 7th Post-operative day.

**CASE 3:** A patient with G3A2 with 36.2 weeks of gestation with breech presentation with PIH and polyhydramnios, admitted with premature rupture of membranes. First two were spontaneous first trimester abortions. Investigation revealed normal PE profile and GTT. USG showed SLIUG of 37-38 wks. with breech presentation with BPP 10/10 and normal Doppler study.

LSCS done in view of fetal distress. Extracted an alive female baby of weight 2.92 kg. Per-op finding showed septate uterus with partial septum (Figure 3). Post- op events were uneventful & discharged on 7th post-operative day.

**DISCUSSION:** Incidence of uterine anomalies is around 3.5-8% in general population. An insult at different levels of uterine development during intrauterine period leads to various uterine anomalies. Partial lack of fusion of two paramesonephric ducts produces a single cervix with varying degrees of separation in two uterine horns, leading to bicornuate uterus. It may be complete or incomplete depending on fundal indentation.

Obstetric complications depends upon the severity of fundal indentation. Incidence of bicornuate uterus is more common among uterine anomalies. Preterm deliveries, miscarriages and breech presentations were more common obstetric complications associated with bicornuate uterus, whereas incidence of infertility in bicornuate uterus is not different from general population.

Majority of women with uterine malformations were asymptomatic. Dysmenorrhea & dyspareunia are common among these population. Surgical reconstructions i.e. metroplasty for the bicornuate uterus can be considered for patients with recurrent miscarriages. Birth rate improves in this selected population from 2-21% to 60-80%.

Partial lack of resorption of midline septum between two mullerian ducts leads to partial/complete septate uterus. The defect is not a cause for infertility but is a common cause for recurrent miscarriages in second trimester. Resection of septum by hysteroscopy gives excellent results in improving birth rates. Fetal survival improves from 13% -91% after hysteroscopic metroplasty. Failure of development of one mullerian duct leads to non-communicating/ communicating rudimentary horn attached to unicornuate uterus (well developed mullerian duct).

Obstetric complications like spontaneous abortions, rudimentary horn pregnancy, IUGR and preterm labor are common with this anomaly. High number of ectopic pregnancies indicates removal of rudimentary horn and its tube when diagnosed.

Failure of fusion of two mullerian ducts results in uterus didelphys. Obstetric complications like spontaneous miscarriage, malpresentation, IUGR and preterm labor are common. They are symptomatic if one side is obstructed. Early diagnosis of obstructed hemivagina and excision of vaginal septum will resolve the gynecological symptoms. Arcuate uterus has usually no adverse impact on complications of pregnancy. Investigations like transvaginal sonography, hysterosalpingography, sonosalpingography, hysteroscopy, MRI, and 3D ultra sound will reveal the uterine malformations.
CASE REPORT

CONCLUSION: Uterine malformations are rare conditions, generally asymptomatic, may have gynecological symptoms & obstetric morbidities. If detected antenatally should be counseled regarding complications. Follow up must be done closely till delivery. If there is repeated miscarriages surgical interventions can help in better outcome.
