Abstract

Background: Aim of the study was to analyze the use of a prophylactic multimodal anti-infective regimen including the probiotic Lactobacillus casei rhamnosus (LCR35) in critically ill term neonates with respect to complications and possible side effects.

Methods: This was a retrospective observational STROBE compliant single-center cohort study of all term infants born between 2005 and 2015 that have been admitted within the first 24 hours of life to the neonatal intensive care unit (NICU) and having been hospitalized for at least 7 days. All neonates received a standardized prophylactic anti-infective treatment with enteral probiotics (LCR35), antifungal agents, and oral gentamycin over the study time starting at the first day of life. Perinatal and neonatal data were collected for descriptive analysis. Complications of neonatal intensive care therapy included late-onset necrotizing enterocolitis (NEC), multiple organ dysfunction syndrome (MODS), ventilator associated pneumonia (VAP), antibiotic-associated diarrhea (AAD), and late-onset sepsis (LOS).

Results: Out of 2940 neonates admitted to the neonatal wards 403 fulfilled the inclusion criteria and comprised the study population. Median gestational age was 38 weeks and birth weight 3300 grams, median length of stay 10 days; 246 (61%) neonates needed ventilatory support and 334 (83%) received antibiotic treatment. None of the neonates developed NEC, MODS, VAP, or AAD. Sixteen (4.0%) neonates developed LOS. Blood cultures were all negative for LCR. Breast milk feeding was evident in 13% (2/16) of the neonates with LOS compared to 30% (121/387) in those without LOS (P = 0.055).

Conclusions: Over an 11-year period use of a standardized prophylactic anti-infective regimen was safe and resulted in a very low incidence of predefined complications in critically ill term neonates.

1. Background

The development of intestinal microbiota in newborn infants, and its potential influence on the infants’ health has become an important issue in literature. Moreover, intensive care in critically ill term neonates potentially alters the intestinal microbiota and possibly enables the growth of pathogens. Hence, dysbiosis of the intestine, or imbalance of intestinal microbiota, increases the risk of diseases with inflammatory background such as late onset sepsis (LOS) and necrotizing enterocolitis (NEC) in neonates (1). Furthermore, these clinical conditions include antibiotic associated diarrhea (AAD), multiple organ dysfunction syndrome (MODS), and ventilator associated pneumonia (VAP), all of them resulting in prolonged hospital stays, increase in the cost of intensive care, and greater risks for mortality (2, 3).

Approximately 10% of all NEC cases occur in term infants (4). Over a 20-year period a NEC rate of 0.43% in full-term Chinese neonates has been reported recently. About 40% of cases had late-onset NEC defined as onset of signs and symptoms after 7 days of life; the associated mortality rate was 11.7% (5).

The risk of VAP generally increases as gestational age decreases (6-9) and has been reported to occur in 9% of all ventilator-days of infants with a birth weight above 2,500 g and rates increasing up to 26% at a birth weight below 750 g (10).

Comparably, the risk of late-onset sepsis (LOS) increases by decreasing gestational age. LOS has been diagnosed in 1 - 2 per 1000 live births with a case fatality rate of 3% in full term infants (11).
Oral aminoglycosides have successfully been investigated in the prevention of NEC in some small and old studies (12, 13) and recently have been effective in preterm animal models of NEC prevention compared to parenteral antibiotics (14). And probiotics as summarized recently in a systematic meta-analysis showed significant benefits on NEC rates and all-cause neonatal mortality (15).

Aim of the study was to evaluate a prophylactic multi-modal anti-infective regimen (16) given within 24 hours of age in critically ill full-term neonates by means of a retrospective observational STROBE compliant single-center cohort study. Our hypothesis was that this regimen might lead to lower complication rates than reported elsewhere.

2. Methods

All term infants admitted to the neonatal intensive care unit (NICU) of the division of neonatology of the Medical University of Graz between 2005 and 2015 were retrospectively evaluated for analysis. All surgical neonates and those with hemodynamically significant congenital heart disease were treated at the PICU and the pediatric surgery ICU, respectively, and not included in the study.

Inclusion criteria were as follows: admission within the first 24 hours of life, stay at the NICU for at least 7 days, and gestational age of 37 to 42 weeks.

Exclusion criteria were as follows: admission to the NICU beyond the first day of life, stay at the NICU for less than 7 days, or death before day 7. Further, neonates were excluded when data were missing or unavailable regarding outcome parameters.

Ethical aspects: due to the design of the study informed consent was not available, thus, patient data were pseudonymized for study purposes and only BR and KL had access to the original data. The study protocol conformed to the ethical guidelines of the Helsinki as reflected in a priori approval by the ethic committee of the Medical University of Graz (number 28-220 ex 15/16 in April 2015) and started in February 2016. Term neonates qualified for NICU treatment in case of need for ventilatory support, signs and symptoms of respiratory distress, need for supplemental oxygen, need for antibiotics, umbilical artery pH < 7.00, Apgar score at 5 minutes ≤ 5, arterial hypotension, floppy infant syndrome, fever, cyanosis, seizures, metabolic acidosis, icterus gravis, or hypoglycemia.

All neonates received a standardized prophylactic multi-modal, anti-infective treatment with enteral probiotics, antifungal agents, and enteral gentamycin starting at the first day of life and ending at discharge (16). The regimen did not change through the study time period and included the following: enteral gentamycin (Refobacin© 40 mg Amp. 15 mg/kg/day divided in 2 doses), Lactobacillus casei rhamnosus (LCR) (Antibiophilus® 1.5 g [contains ≥ 1.5 × 10⁸ colony forming units - CFU] per day divided in 2 doses), and enteral nystatin (Mycostatin® 1 mL = 100.000 IU/kg per day divided in 4 doses).

Outcome parameters were checked for in all medical records of the neonates using the electronic patient data monitoring system (PDMS, Sanitas, Austria) at the NICU as follows:
- Late-onset necrotizing enterocolitis - NEC,
- Multiple organ dysfunction syndrome - MODS,
- Ventilator associated pneumonia - VAP,
- Antibiotic-associated diarrhea - AAD,
- Late-onset sepsis - LOS (onset > 7 days of age).

The standardized enteral feeding regimen applied to all term infants at the NICU and remained unchanged through the study time period. Enteral feeding of breast milk (expressed breast milk or pooled human milk if available) or formula was initiated at day 1. A volume of 5 to 10 mL was initiated every 4 hours in case of well-appearing neonate. Negative blood cultures were available following 72 hours.

2.1. Data Collection

Data were collected from the local electronic database openMedocs® for all infants regarding gender, gestational age (weeks), birth weight (grams), small for gestational age (birth weight below 10. percentile), umbilical artery pH, length of stay (days), Apgar scores at 1, 5, 10 minutes, days on ventilator support (invasive mechanical plus continuous positive airway pressure - CPAP - ventilation), spontaneous birth, cesarean section, breast milk feeding, formula feeding, combined human milk and formula feeding, duration of antibiotic treatment (days), and main diagnosis for treatment at the NICU. Infectious events were always tested by blood culture for LCR.
2.2. Definition of Outcome Parameters

Late-onset NEC was defined according to the modified Bell’s criteria as stage IIa or more (17, 18) occurring later than 7 days (5). Signs and symptoms included abdominal pain, bloody stools, ileus (subileus), and pneumatosis intestinalis.

A MODS was defined as the presence of at least 2 of 6 defined criteria for multiple organ dysfunction (19, 20) that was mainly adapted from Goldberg et al. (19) not using the scoring system published recently (20):

- Cardiovascular dysfunction (any of the following): despite isotonic intravenous bolus ≥ 40 mL/kg; systolic blood pressure < 5% for age or need for vasopressor drugs; capillary refill time > 3 seconds; urine output < 0.5 mL/kg/h
- Respiratory dysfunction (any of the following): PaCO₂ > 65 torr or 20 mmHg over baseline. Proven need for > 50% FiO₂ to maintain saturation ≥ 92%
- Neurologic dysfunction (any of the following): seizures, irritability, and lethargy, any different from baseline neurologic function
- Thrombocytopenia: platelets < 80,000/µL or decline of 50% from highest value over past 3 days in neonates with baseline low platelets (< 150,000/µL)
- Renal dysfunction: creatinine ≥ 2 times upper limit for age or 2-fold increase in baseline creatinine in neonates with baseline elevations in creatinine
- Hepatic dysfunction (any of the following): total bilirubin not applicable to newborn. ALT (alanine transaminase) 2 times upper limit of normal for age or 2-fold increase in baseline abnormal ALT

For the diagnosis of VAP, the patient was required to have received mechanical ventilation for at least 48 hours and to have developed new and persistent radiographic evidence of focal infiltrates lasting for a minimum of 48 hours after the initiation of mechanical ventilation. In addition, these patients had to receive antibiotics for treatment of VAP for at least 7 days (6).

AAD was defined as otherwise unexplained diarrhea that occurs in association with the administration of antibiotics. Its presence was characterized by a change in the normal stool frequency with at least 3 loose or watery stools daily for 3 days (3).

LOS was defined as a nosocomial bacterial infection not present or incubating at the time of NICU admission and occurring > 72 hours after NICU admission. We did not differentiate between culture proven and clinical sepsis (clinical symptoms + 2 or more abnormal values including white blood cell count, neutrophils, immature to total neutrophil ratio > 0.2 and C-reactive protein > 8 mg/L) (21).

Statistical analyses were performed using the t-test and Wilcoxon test for numerical data and the chi-square-test using Yates’ correction and Fisher’s exact test as appropriate for categorical data. For all statistical tests, a level of significance of 0.05 was used. Descriptive statistics were done using Microsoft Excel 2007 (Microsoft Corporation, Redmond, WA, USA, 2007), further analyses were done with SPSS version 17 (SPSS Inc., Chicago, IL, USA, 2008).

3. Results

During the study period 2940 term neonates were hospitalized at the neonatal wards, and 1301 neonates were admitted to the NICU. A further 897 neonates had to be excluded, thus the final study population comprised 403 neonates. Details are provided in Figure 1. Their median gestational age was 38 weeks, birth weight 3300 grams, and 56% were of male gender. Demographic data and hospitalization details at the NICU are shown in Table 1.

Main diagnoses (283/403, 70%) included early-onset sepsis/bacterial infection (n = 119), asphyxia (n = 43), meconium aspiration syndrome (n = 40), respiratory distress syndrome (n = 24), delayed adaption (n = 22), wet lung (n = 17), congenital diaphragmatic hernia (n = 9), and pneumonia (n = 9). Other diagnoses included symptomatic hypoglycemia, neonatal abstinence syndrome, apparent life threatening event, floppy infant syndrome, icterus gravis, polycythemia/hyper viscosity syndrome, cyanosis, dystrophy below 3rd percentile, congenital malformation,
fetopathia diabetica, gastrointestinal hemorrhage, pneumothorax, thrombosis, hemorrhagic infarction, and some rare diseases including undine syndrome.

None of the neonates exhibited NEC, MODS, VAP or AAD. Sixteen (4.0%) neonates developed LOS (Table 2). Blood cultures were positive in 3/16 of the cases for coagulase negative staphylococci, and all were negative for LCR. Breast milk feeding was evident in 13% (2/16) of the neonates with LOS, compared to 30% (121/387) in the total group, differences were not significant, but there was a trend to lower breast feeding rates in the LOS group (P = 0.055).

### Table 1. Demographic Data and Selected Hospitalization Details of 403 Term Neonates Being Treated at Least for 7 Days at the NICU Between 2005 and 2015

| Valuesa |  |
|---------|---|
| Male: female | 226 (56): 177 (44) |
| Gestational age, w | 38 (37 - 42) |
| Birth weight, g | 3300 (2500 - 5300) |
| Small for date (< 10 percentile) | 41 (10) |
| Spontaneous birth: caesarean section | 182 (45): 221 (55) |
| Umbilical artery pH | 7.23 (6.38 - 7.46) |
| Apgar at 1/5/10 minutes | 8 (1-10)/9 (1-10)/9 (1-10) |
| Length of stay, days | 10 (7 - 10) |
| Ventilatory support | 246 (61) |
| Days on ventilatory support | 5 (1 - 45) |
| Antibiotics | 334 (83) |
| Duration of antibiotic treatment | 7 (2 - 43) |
| Breast milk feeding | 123 (31) |
| Formula feeding | 63 (16) |
| Breast milk and formula | 227 (54) |

Values are expressed as No. (%) or median (range). 

4. Discussion

Our prophylactic multimodal, anti-infective regimen given to full-term neonates hospitalized at the NICU over an 11-year period was successful by means of completely avoiding late-onset NEC, MODS, VAP, and AAD. The rate of LOS was low with 4%. Lower rates of breastfeeding (differences marginally not significant) might have played a role. No side effects with the treatment regimen were observed.

Limitations of the study include the lower evidence level of a retrospective compared to a prospective cohort analysis and the interpretation of data in the absence of a control group. As far as our prophylactic multimodal, anti-infective regimen resulted in very low NEC rates (16) we felt that a placebo controlled trial might be unethical. Hence, we compared our complication rates to the published evidence in term critically ill neonates. Another critical point is the use of an oral antibiotic like gentamycin which is based on small and old studies (12, 13). Nevertheless, none of the gentamycin treated neonates developed NEC and none died in contrast to a 10% mortality rate in the controls (12). Recently, NEC lesions were completely prevented by antibiotics (ampicillin, gentamicin, and metronidazole) given via the enteral in contrast to the parenteral route in an animal model of preterm pigs (14). Our longstanding experience in the use of enteral gentamycin has revealed neither a change in ESBL producing enterobacteria in stool surveillance cultures nor in antimicrobial sensitivity patterns (22). This is also the case for the use of LCR resulting in very low NEC rates as compared to other studies (16).

Studies on complications of intensive care therapy including late-onset NEC, MODS, VAP, AAD and LOS in term infants are scarce. In a prospective investigation on the effect of probiotic treatment in 100 critically ill-term infants (randomized 1:1) LOS occurred in 4 vs 8%, MODS in 6 vs 16%, nosocomial pneumonia in 16 vs 36%, NEC in 4 vs 6%, and AAD in 6 vs 10% compared to placebo demonstrating a significant reduction in MODS and pneumonia (1). The preparation (30 billion viable lyophilized bacteria) consisted of

Table 2. Incidence of Common Complications of Intensive Care Treatment in 403 Term Neonates Being Treated at Least for 7 Days at the NICU Between 2005 and 2014

| Valuesa |  |
|---------|---|
| Necrotizing enterocolitis (grade ≥ IIa*) | 0 (0) |
| Multi-organ dysfunction syndrome | 0 (0) |
| Ventilator associated pneumonia | 0 (0) |
| Late-onset sepsis | 16 (4.0) |
| Antibiotics-associated diarrhea | 0 (0) |

Values are expressed as number (%) or median (range; *according to the modified criteria of Bell.)
2 strains of *Lactobacillus* (*L. casei* and *L. acidophilus*), *Bacillus subtilis* and *Enterococcus faecalis*. Compared to our data this trial reported on a comparable rate of LOS with 4%, but higher rates of all other complications.

Septic shock with MODS has been noted in 1.3% of a retrospectively evaluated cohort of 3,800 neonates admitted to the NICU over a 6-year period (23). Mortality rates were remarkably high with a rate of 71% in extremely preterm infants. Thus, a regimen as used in our cohort study is able to prevent severe morbidity and marked mortality that was as low as 12%. Mean duration of MODS has been reported with 11 days lasting until 28 days in preterm infants, and mortality rate was 27.5% (20). Of 1806 enrolled pediatric patients 171 (9.5%) were neonates who had a significantly higher risk of MODS (14.6% vs 5.5%) and risk of associated death (75.4% vs 50.9%) compared to older infants (age > 28 days of life) and children (24). Pediatric illnesses with MODS comprise severe infections, multiple trauma, surgery for congenital heart defects, or transplantations (25). Unbalanced inflammatory processes and activation of coagulation lead to the capillary leak syndrome and acute respiratory distress syndrome. Neuroendocrine and metabolic responses lead to insufficiencies of the adaptive immune response with subsequent increased risks for metabolic responses leading to insufficiencies of the adaptive immune response with simultaneous increased risks for the acute respiratory distress syndrome. Neuroendocrine and metabolic responses lead to insufficiencies of the adaptive immune response with subsequent increased risks for nosocomial infections, which pose children further at high risk for increased morbidity and mortality (25). Thirty-one of 114 (27.2%) pediatric liver transplantation recipients developed MODS (involving two or more organs) and 18 (15.8%) died during hospitalization of whom 16 (89%) had MODS (26). Mortality increased the more organ systems were involved (from 2 organ systems with 29.4% to 80% with 4 organ systems). Adult critically ill patients showed a reduction in their MODS scores 3 days after treatment with viable probiotics (900 billion viable *Lactobacillus* consisting of 4 strains of *Lactobacillus* (*L. casei*, *L. plantarum*, *L. acidophilus*, and *L. delbrueckii* subsp. *bulgaricus*), 3 strains of *Bifidobacterium* (*B. longum*, *B. breve*, and *B. infantis*) and *Streptococcus salivarius* subsp. *thermophilus* (2). All together results suggest that Lactobacilli play a major beneficial role in regard to a significant mortality rate associated with MODS (15). Beyond a lot of randomized trials on probiotics to prevent LOS there is still missing data regarding the optimal strain(s), dose, time to start and duration of probiotic therapy, as well as the taxonomy and quality of currently available probiotic formulations and products. To date *Bifidobacterium* and *Lactobacillus* spp. are the most studied probiotic organisms in neonates (27).

In conclusion, our findings on very low complication rates of neonatal intensive care therapy in term infants look promising but need further validation (by other centers). The use of our prophylactic multimodal anti-infective regimen was very safe; there were no side effects of any kind to be detected.
