Abstract
Invasive ductal carcinoma (IDC) is the most common subtype of breast tumor. There were many cases reported about the treatment and adjuvant therapies. The simultaneously occurrence of breast carcinoma with cutaneous myiasis is, to our knowledge, a unique presentation. A 50-year-old female known case of breast cancer presented to the surgical department at Ziauddin Hospital Karachi with complaints of pain, redness, blackening, and a foul smelling, discharging wound on her left breast. The wound was debrided thoroughly with povidone-iodine and about 52 maggots were removed, which were identified as Chrysomya bezziana. The patient was hospitalized and received amoxicillin and ivermectin according to protocol. This case report is pertinent to public health professionals and oncologists in the view of the social impact of myiasis.

Keywords
Myiasis, Parasitic Infection, Invasive ductal carcinoma
**Introduction**

Breast carcinoma is the second-leading cause of cancer-related mortality in women. Invasive ductal carcinoma is most common histological subtype of breast carcinoma. Myiasis is the dipterous larvae infestation of human or animal tissues. It is typically associated with inadequate personal hygiene due to lack of awareness among individuals in tropical and subtropical countries. Dipterous larvae in the feeding life cycle of may be found in living or dead tissues. Many treatment options are available for invasive ductal carcinoma found with gangrenous tissues, with radiotherapy considered highly commendable in order to reduce disease recurrence.

**Case report**

A 50-year-old female presented to the surgical department at Ziauddin Hospital Karachi with complaints of pain, redness, blackening, and a foul smelling and discharging wound in the left breast. She had a history of invasive ductal carcinoma which was diagnosed 2.5 years previously but could not get treatment for financial reasons. On examination, the patient looked weak and lethargic. She had a fever of 101°F (38.3°C) The majority of the breast was hard in consistency with a purulent sanguineous discharging ulcer, which was foul smelling due to superimposed bacterial infection. The surrounding skin was gangrenous and numerous grayish maggots were seen crawling around.

The wound was debrided thoroughly with povidone-iodine in the emergency room and about 52 maggots were removed carefully, preserved and sent for entomological review which were identified as *Chrysomya bezziana*. The maggots were 15 to 20 mm long, whitish or greyish in color without body process. There is an enlargement of anterior spiracle and darkened portion of trunks, posterior spiracle extended three or four abdominal segments (Figure 2 and Figure 3). The patient was given wide-spectrum antibiotic amoxicillin 1 g twice a day for 7 days and Ivermectin 6 g twice a day for 1 day according to protocol. Total mastectomy was performed in the oncology department at Ziauddin Hospital as part of palliative treatment due to the gangrene and myiasis. She was also started on radiotherapy and chemotherapy for ductal carcinoma; the chemotherapeutic regimen included capecitabine 1200 mg/m² twice a day for 21 days with repeat cycles after every 21 days for 6 weeks. Total radiation dose was 5000 cGy delivered in 25 fractions 5 days a week for 6 weeks. Two months after ceasing her treatment with ivermectin and amoxicillin, breast tissue was healed and surrounded by scarring.

**Discussion**

Cutaneous myiasis is a rare entity. It is an infestation of human skin with maggots of flies which feed on host tissues. There are
two classifications of myiasis, anatomical and ecological. The first description of myiasis was given by Hope in 1840. Since then many cases of myiasis affecting different human organs have been described.1,2,6,7. Francesconi1 used an anatomical classification of myiasis, in which it is grouped into sanguinivorous or bloodsucking, cavitary, wound, cutaneous, furuncular and migratory myiasis.

Flies lay eggs which hatch in a humid and warm environment, and larvae can get access directly to skin from wet clothes, buds or insects. Cutaneous myiasis is very uncommon; the majority of cases are caused by human botfly (Dermatobia hominis)1,3,5. Cutaneous myiasis is presented as a slow developing ulcer or boil. Some of the physical presentations of mastitis are similar to those of carcinoma of the breast18. It is important to note that an affected breast with myiasis, which appears like fungating mass with an ulcer, can be sometimes misdiagnosed and is confused with tuberculosis, mycosis, actinomycosis, furunculosis, chronic breast abscess, fungating malignancies, periductal mastitis, inflammatory carcinoma of the breast and cellulitis10,11. Therefore, it is very important to keep this rare but possible disease in the differentials when diagnosing the condition.

Sample larvae should be promptly preserved after removal in order to maintain their identity, because subsequent treatment is based on the type of the organism identified. Various techniques are available to remove larvae without affecting their shape and structure12,13. Risk factors should also be kept in mind, such as living in endemic areas, the characteristic intense itching of the affected breast, offending maggots (seen via a hand magnifying glass) are invaluable aids to the diagnosis and treatment. Poor personal hygiene is an important cause of myiasis; it can be prevented by proper sanitation, good personal hygiene, spraying insecticides for flies and removal of garbage from nearby streets. Clothes should be worn after washing, drying in sunlight and ironing in order to prevent myiasis14.

After the treatment of myiasis, any remaining ulcer should be biopsied in order to rule out any malignancy, as in our case, cutaneous (breast) myiasis simultaneously occurred with invasive ductal carcinoma (Figure 2) and after surgical removal (Figure 3) was confirmed with a biopsy (Figure 1). Invasive ductal carcinoma is the most common type of breast cancer, making up nearly 70–80% of all breast cancer cases. Invasive or infiltrative ductal carcinoma is the presence of abnormal cancer cells in the lactiferous ducts that have spread into other parts of the breast tissue. It can also metastasize to other parts of the body. Histological examination of breast cancer is mandatory to confirm the diagnosis and to establish different pathological prognostic factors15,16.

Conclusion
Cutaneous myiasis with breast cancer is a rare but possible entity and we should include it in our differentials which is important to avoid any further delay in diagnosis and adequate treatment in the future.

Data availability
All data underlying the results are available as part of the article and no additional source data are required.

Consent
Written informed consent for publication of clinical details and clinical images was obtained from the patient.

Grant information
The author(s) declared that no grants were involved in funding this work.

The authors presented a rare breast invasive ductal carcinoma complicated with cutaneous Myiasis.

Can the authors provide more detail about physical examination and diagnostic tests of breast cancer? For example: did the authors performed CT scanning of liver, lung, bone and brain? They should present the disease stage of the case. Did they finish the immunohistochemistry staining of breast cancer, including hormone receptor (ER, PR) and cerbB-2? It will be useful for other practitioners.

I'd like to remind the importance of breast cancer screening in developing countries.

Is the background of the case's history and progression described in sufficient detail?  
Yes

Are enough details provided of any physical examination and diagnostic tests, treatment given and outcomes?  
Partly

Is sufficient discussion included of the importance of the findings and their relevance to future understanding of disease processes, diagnosis or treatment?  
Yes

Is the case presented with sufficient detail to be useful for other practitioners?  
Partly

The authors present an interesting case of ulcerative breast carcinoma with *Chrysomya bezziana* infestation.

- It is necessary to explain the reasons for which ivermectin was used. In addition: why this dosage and duration?

- It is also necessary to add that *Cordylobia anthropophaga* is typical of Western Africa, *Cordylobia rodhaini* of Eastern Africa and *Dermatologia hominis* of Latin America.

- A language edit is required.

Is the background of the case’s history and progression described in sufficient detail? Yes

Are enough details provided of any physical examination and diagnostic tests, treatment given and outcomes? Yes

Is sufficient discussion included of the importance of the findings and their relevance to future understanding of disease processes, diagnosis or treatment? Yes

Is the case presented with sufficient detail to be useful for other practitioners? Yes

Competing Interests: No competing interests were disclosed.

Reviewer Expertise: Infectious and parasitic diseases of the skin. Tropical dermatology.

I confirm that I have read this submission and believe that I have an appropriate level of
expertise to confirm that it is of an acceptable scientific standard, however I have significant reservations, as outlined above.

The benefits of publishing with F1000Research:

- Your article is published within days, with no editorial bias
- You can publish traditional articles, null/negative results, case reports, data notes and more
- The peer review process is transparent and collaborative
- Your article is indexed in PubMed after passing peer review
- Dedicated customer support at every stage
