Abstract
DNA transcription is intrinsically complex. Bioinformatic work with transcription factors (TFs) is complicated by a multiplicity of data resources and annotations. The Bioconductor package TFutils includes data structures and functions to enhance the precision and utility of integrative analyses that have components involving TFs. TFutils provides catalogs of human TFs from three reference sources (CISBP, HOCOMOCO, and GO), a catalog of TF targets derived from MSigDb, and multiple approaches to enumerating TF binding sites. Aspects of integration of TF binding patterns and genome-wide association study results are explored in examples.

Keywords
Transcription factors, Gene expression, Gene regulation, Bioconductor

First published: 05 Feb 2019, 8:152 https://doi.org/10.12688/f1000research.17976.1
Introduction
A central concern of genome biology is improving understanding of gene transcription. In simple terms, transcription factors (TFs) are proteins that bind to DNA, typically near gene promoter regions. The role of TFs in gene expression variation is of great interest. Progress in deciphering genetic and epigenetic processes that affect TF abundance and function will be essential in clarifying and interpreting gene expression variation patterns and their effects on phenotype. Difficulties of identifying functional binding of TFs, and opportunities for using information of TF binding in systems biology contexts, are reviewed in Lambert et al.¹ and Weirauch et al.².

This paper describes an R/Bioconductor package called TFutils, which assembles various resources intended to clarify and unify approaches to working with TF concepts in bioinformatic analysis. Computations described in this paper can be carried out with Bioconductor version 3.8. The package can be installed with

```r
# use install.packages("BiocManager") if not already available
library(BiocManager)
install("TFutils")
```

In the next section we describe the basic concepts of enumerating and classifying TFs, enumerating TF targets, and representing genome-wide quantification of TF binding affinity. This is followed by a review of the key data structures and functions provided in the package, and an example in cancer informatics.

The present paper does not deal directly with the manipulation or interpretation of sequence motifs. An excellent Bioconductor package that synthesizes many approaches to these tasks is universalmotif.

Basic concepts of transcription factor bioinformatics
Enumerating transcription factors
Given the importance of the topic, it is not surprising that a number of bioinformatic research groups have published catalogs of transcription factors along with metadata about their features. Standard nomenclature for TFs has yet to be established. Gene symbols, motif sequences, and position-weight matrix catalog entries have all been used as TF identifiers.

In TFutils we have gathered information from four widely used resources, focusing specifically on human TFs: Gene Ontology (GO, Ashburner et al.¹, in which GO:0003700 is the tag for the molecular function concept “DNA binding transcription factor activity”), CISBP (Catalog of Inferred Sequence Binding Preferences) (Weirauch et al.²), HOCOMOCO (Homo sapiens Comprehensive Model Collection) (Kulakovskiy et al.⁴), and the “c3 TFF (transcription factor target)” signature set of MSigDb (Molecular Signatures Database) (Subramanian et al.⁵). Figure 1 depicts the sizes of these catalogs, measured using counts of unique HGNC gene symbols. The enumeration for GO uses Bioconductor’s org.Hs.eg.db (version 3.7.0) package to find direct associations from GO:0003700 to HGNC symbols. The enumeration for MSigDb is heuristic and involves parsing the gene set identifiers used in MSigDb for exact or close matches to HGNC symbols. For CISBP and HOCOMOCO, the associated web servers provide easily parsed tabular catalogs.

Classification of transcription factors
As noted by Weirauch et al.², interpretation of the “function and evolution of DNA sequences” is dependent on the analysis of sequence-specific DNA binding domains. These domains are dynamic and cell-type specific (Gertz et al.⁶). Classifying TFs according to features of the binding domain is an ongoing process of increasing intricacy. Figure 2 shows excerpts of hierarchies of terms related to TF type derived from GO (on the left) and TFclass (Wingender et al.⁷). There is a disagreement between our enumeration of TFs based on GO in Figure 1 and the 1919 shown in AmiGO, as the latter includes a broader collection of receptor activities.

Table 1 provides examples of frequently encountered TF classifications in the CISBP and HOCOMOCO catalogs. The numerical components of the HOCOMOCO classes correspond to TFClass subfamilies (Wingender et al.⁷).

Enumerating TF targets
The Broad Institute MSigDb (Subramanian et al.⁵) includes a gene set collection devoted to cataloging TF targets. We have used Bioconductor’s GSEABase package (version 1.45.0) to import and serialize the gmt representation of this collection.
Figure 1. Sizes of transcription factor (TF) catalogs and of intersections based on HGNC (HUGO Gene Nomenclature Committee) symbols for TFs.

Figure 2. Screenshots of AmiGO and TFClass hierarchy excerpts.
Names of TFs for which target sets are assembled are encoded in a systematic way, with underscores separating substrings describing motifs, genes, and versions. Some peculiarity in nomenclature in the MSigDb labels can be observed:

```
grep("NFK", names(TFutils::tftColl), value=TRUE)
```

```
# [1] "NFKAPPAB65_01"    "NFKAPPAB_01"    "NFKB_Q6"
# [4] "NFKB_C"           "NFKB_Q6_01"    "GGGNNTTTCC_NFKB_Q6_01"
```

Manual curation will be needed to improve the precision with which MSigDb TF target sets can be associated with specific TFs or motifs.

### Quantitative predictions of TF binding affinities

In this subsection we address representation of putative binding sites. First we illustrate how to represent sequence-based affinity measures and the binding site locations implied by these. We then discuss use of results of ChIP-seq experiments for cell-type-specific binding site enumeration.

**Affinity scores based on reference sequence.** The FIMO algorithm of the MEME suite (Grant et al.⁸) was used to score the human reference genome for TF binding affinity for 689 motif matrices to which genes are associated. Full details are provided in Sonawane et al.⁹. Sixteen (16) tabix-indexed BED files are lodged in an AWS S3 bucket for illustration purposes.

```
library(GenomicFiles)
data(fimo16)
fimo16
```
## GenomicFiles object with 0 ranges and 16 files:
## files: M0635_1.02sort.bed.gz, M3433_1.02sort.bed.gz, ..., M6159_1.02sort.bed.gz, M6497_1.02sort.bed.gz
## detail: use files(), rowRanges(), colData(), ...

```r
head(colData(fimo16))
```

```
  Mtag        HGNC
  <character> <character>
  1     M0635_1      DMRTC2
  2     M3433_1       HOXA3
  3     M3467_1        IRF1
  4     M3675_1       POU2F1
  5     M3698_1      POU2F1
  6     M3966_1       STAT1
```

We harvest scores in a genomic interval of interest (bound to fimo16 in the rowRanges assignment below) using reduceByFile. This yields a list with one element per file. Each such element holds a list of scanTabix results, one per query range.

```r
library(BiocParallel)
register(SerialParam())  # important for macosx?
rowRanges(fimo16) = GRanges("chr17", iRanges(38.077e6, 38.084e6))
rr = GenomicFiles::reduceByFile(fimo16, MAP=function(r,f)
  scanTabix(f, param=r))
```

scanTabix produces a list of vectors of text strings, which we parse with data.table::fread. The resulting tables are then reduced to a genomic location and -log10 of the p-value derived from the binding affinity statistic of FIMO in the vicinity of that location.

```r
asdf = function(x) data.table::fread(paste0(x, collapse="\n"), header=FALSE)

gg = lapply(rr, function(x) {
  tmp = asdf(x[[1]][[1]])
  data.frame(loc=tmp$V2, score=-log10(tmp$V7))
})

for (i in 1:length(gg))  gg[[i]]$tf = colData(fimo16)[i,2]
```

It turns out there are too many distinct TFs to display names individually, so we label the scores with the names of the associated TF families as defined in CISBP.

```r
matchcis = match(colData(fimo16)[,2], cisbpTFcat[,2])
fann = cisbpTFcat[matchcis,]$Family_Name
for (i in 1:length(gg))  gg[[i]]$tffam = famn[i]

nn = do.call(rbind, gg)
```

A simple display of predicted TF binding affinity near the gene ORMDL3 is provided in Figure 3.

### TF binding predictions based on ChIP-seq data from ENCODE.

The ENCODE project provides BED-formatted reports on ChIP-seq experiments for many combinations of cell type and DNA-binding factors. TFutils includes a table encode690 that gives information on 690 experiments involving pairs formed from 91 cell lines and 161 TFs for which results have been recorded as GRanges instances that can be acquired with the Annotation-Hub (version 2.15.4) package. Positional relationships between cell-type specific binding sites and genomic features can be investigated. An illustration is given in Figure 4, in which it is suggested that in HepG2 cells, CEBPB exhibits a distinctive pattern of binding in the vicinity of ORMDL3.

### Summary

We have compared enumerations of human transcription factors by different projects, provided access to two forms of binding domain classification, and illustrated the use of cloud-resident genome-wide binding predictions. In the next section we review selected details of data structures and methods of the TFutils package.
Figure 3. TF binding in the vicinity of gene **ORMDL3**. Points are -log10-transformed FIMO-based p-values colored according to TF class as annotated in CISBP. Segments at bottom of plot are transcribed regions of **ORMDL3** according to UCSC gene models in build hg19.

Figure 4. Binding of CEBPB in the vicinity of **ORMDL3** derived from ChIP-seq experiments in four cell lines reported by ENCODE. Colored rectangles at top are regions identified as narrow binding peaks, arrows in bottom half are exons in **ORMDL3**. Arrows sharing a common vertical position are members of the same transcript as cataloged in Ensembl version 75.
Methods

Implementation

The TFutils package is designed to lower barriers to usage of key findings of TF biology in human genome research. TFutils is supplied as a conventional R package distributed with, and making use of, the Bioconductor software ecosystem. TFutils includes ready-to-use reference data, tools for visualizing binding sites, and tools that simplify integrative use of TF binding information with GWAS findings.

Data resources

Catalogs. Two reference resources have been collected into the TFutils package as data.frame instances. These are cisbpTFcat (CISBP: 7592 x 28), and hocomoco.mono.sep2018 (mononucleotide models, full catalog, 769 x 9). These data.frames are snapshots of the CISBP and HOCOMOCO catalogs

Indexed BED in AWS S3. As described above fimo16 provides programmatic access to FIMO scores for 16 TFs, using the GenomicFiles (version 1.19.0) protocol.

Annotated reference to ENCODE ChIP-seq results. encode690 simplifies programmatic access to TF:cell-line combinations available in Bioconductor AnnotationHub (version 2.15.4).

TF targets enumerated in MsigDb. The c3-TFT (TF targets) subset from MsigDb is provided as a GeneSet-Collection instance as defined in GSEABase.

Illustrative GWAS records. The full EBI/EMBL GWAS catalog is available in the gwascat package (version 2.15.0); for convenience, an excerpt focusing on chromosome 17 is supplied with TFutils as gwascat_hg19_chr17.

Infrastructure for interacting with components of TFutils

Interactive enumeration of TF targets implicated in GWAS. The TFtargs function runs a shiny app that permits selection of a TF in the nomenclature of the MsigDb c3/TFT gene set collection. The app will search an object provided by the gwascat package for references in the MAPPED_GENE field that match the targets of the selected TF. Figure 5 gives an illustration.

The TFCatalog S4 class. Reference catalogs for TF biology are structured with the TFCatalog class. Two essential components for managing a catalog are the native TF identifier for the catalog and the HGNC gene symbol typically used to name the TF. The TFCatalog class includes a name field to name the catalog, and a character vector with elements comprised of the native identifiers for catalogued TFs.

Figure 5. TFtargs() screenshot. This example reports on recent EBI GWAS catalog hits on chromosome 17 only.
For example, CISBP uses T004843_1.02 to refer to motifs associated with gene TFAP2B. There are five such motifs, three derived from SELEX, one from Transfac, and one from Hocomoco.

A data.frame instance that has an obligatory column named ‘HGNC’ can include any collection of fields that offer metadata about the TF in the specified catalog. Here is how we construct and view a TFCatalog object using the CISBP reference data.

data(cisbpTFcat)
TFs_CISBP = TFCatalog(name="CISBP.info",
nativeIds=cisbpTFcat[,1],
HGNCmap = cisbpTFcat)

TFs_CISBP
## TFutils TFCatalog instance CISBP.info
##  7592 native Ids, including
##    T004843_1.02 ... T153733_1.02
##  1551 unique HGNC tags, including
##    TFAP2B TFAP2B ... ZNF10 ZNF350

**Operation: Installation**

The TFutils package can be installed in any version of R subsequent to 3.5.0, and therefore will be usable on Unix, Windows, or Mac platforms. The preferred method of installation employs the CRAN package BiocManager, through the R command BiocManager::install("TFutils"). All necessary dependencies will be installed through this process.

**Operation: Use cases**

In this section we consider applications of the tools in genetic epidemiology. First we look for TFs that may harbor variants associated with traits in the EBI GW AS catalog. Then we show how to enumerate traits associated with targets of a selected TF.

**TFs that are direct GWAS hits for a given trait.** directHitsInCISBP accepts a string naming a trait, and returns a data.frame of TFs identified as “mapped genes” for the trait, with their TF “family name”.

library(dplyr)
library(magrittr)
library(gwascat)
data(ebicat37)
directHitsInCISBP("Rheumatoid arthritis", ebicat37)

## Joining, by = "HGNC"
##        HGNC Family_Name
## 1  ARID5B ARID/BRIGHT
## 7   EOMES   T-box
##15  GATA3     GATA
##35  JAZF1   C2H2 ZF
##37  MECP2      MBD
##45    MTF1   C2H2 ZF
##57    REL       Rel
##65  STAT4      STAT
##79    AIRE      SAND
##82    IRF5       IRF

**Traits mapped to genes that are targets of a given TF**

topTraitsOfTargets will acquire the targets of a selected TF, check for hits in these genes in a given GWAS catalog instance, and tabulate the most commonly reported traits.

tt = topTraitsOfTargets("MTF1", TFutils::tftColl, ebicat37)
## remapping identifiers of input GeneSetCollection to Symbol...

## done

```r
def(p,1)
```

### Discussion

Sources and consequences of variations in DNA transcription are fundamental problems for cell biology, and the projects we have made use of for cataloging transcription factors are at the boundaries of current knowledge.

It is noteworthy that the four resources used for Figure 1 agree on names of only 119 TFs. The fact that CISBP distinguishes 475 TFs that are not identified in any other source should be better understood. We observe that the ascription of TF status to AHRR is based on its sharing motifs with AHR (see http://cisbp.ccbr.utoronto.ca/TFreport.php?searchTF=T014165_1.02).

Figure 2 and Table 1 show that the classification of TFs is now fairly elaborate. Use of the precise terminology of the TFClass system to label TFs of interest at present relies on associations provided with the HOCOMOCO catalog.

As population studies in genomic and genetic epidemiology grow in size and scope, principles for organizing and prioritizing loci associated with phenotypes of interest are urgently needed. Figure 5 shows that loci associated with phenotypes related to kidney function, lung function, and IL-8 levels are potentially unified through the fact that the GWAS hits are connected with genes identified as targets of VDR (vitamin D receptor). This example limited attention to hits on chromosome 17; the TFtargs tool permits ad libitum exploration of phenotype-locus-gene-TF associations. Our hope is that the tools and resources collected in TFutils will foster systematic development of evidence-based mechanistic network models for transcription regulation in human disease contexts, thereby contributing to the development of personalized genomic medicine.
Data availability
With the exception of the FIMO scoring data (fimo16), all data underlying the results are available as part of the article and no additional source data are required.

fimo16 links to indexed bed files in a public S3 bucket funded by the Bioconductor foundation. The underlying data is sourced from Sonawane et al. 2017 https://doi.org/10.1016/j.celrep.2017.10.001

Software availability
Source code is available from GitHub: https://github.com/vjcitn/TFutil
Archived source code: https://doi.org/doi:10.18129/B9.bioc.TFutil
Licence: Artistic License 2.0

10. Carey V, Gopaulakrishnan S: TFutils: TFutils. R package version 1.2.0. 2018. http://www.doi.org/10.18129/B9.bioc.TFutils
TFutils is a Bioconductor package meant to help users study TF binding in the human genome. The tool integrates several resources such as Gene Ontology (GO), CISBP, HOCOMOCO, and MSigD (the Molecular Signature Database). The paper describes how to tackle basic problems users are faced with when trying to work with TFs, in particular the TF classification, the gene targets identification, and, ultimately, the prediction of TF binding affinities.

This article looks more like a software tutorial than a scientific article. As software has to evolve in order keep up with user needs, the text will have to be updated on a regular basis in the future, in order to remain up-to-data as well. This is fine if F1000Research accepts updates and supports versioning of articles. Otherwise, another format should be chosen for presenting this tool.

Just by reading the article, we didn't get a clear impression of what is inside TFutils. Going through the command examples was helpful in this respect. Nevertheless, we have doubts whether we would be able to use this package in a productive manner in the future. The promise that "TFutils lowers the barriers of usage of key findings of TF biology" holds only for expert users of Bioconductor, who are already familiar with all the other packages mentioned in this article and necessary to reproduce the results.

The current manuscript has several shortcomings. At a general level, it is not very transparent to the naïve reader what is actually new from this package and what functionalities are provided by the many other Bioconductor packages referred to in the text. Fortunately, we found a well-organized reference manual for TFutils version 1.2.0 on the internet, which clarified this issue for us. A URL to this document should have been included in the article.
As this is a tutorial-style document, it would be helpful to provide complete R code for reproducing Figures 3 and 4. While Figure 3 is relatively easy to generate, it took us at least half a day to reproduce Figure 4. A major limitation is that the fimo16 object, upon which Figure 3 is based, contains only TF affinity data for 16 out of 689 scanned TF motif matrices.

Figure 3 shows the predicted binding sites for 16 TFs in a selected genomic region. Already with such a small number of TFs, the Figure is pretty crowded with dots. One wonders what it would look like if all 689 FIMO-scanned motif matrices were considered. In view of the density of motif matches it seems doubtful whether any biological insights can be gained from such a plot. Some guidance for the interpretation is needed.

Figure 4 shows ENCODE binding peaks for CEBPB in the same genomic region that was used for Figure 3. Naturally, we were curious to know whether the peaks seen in this Figures co-localize with corresponding motif matches in Figure 3. Unfortunately, CEBPB is not included in the fimo16 collection. To exemplify the power of the tool, it would have been preferable to choose an example where the reader can crosscheck the consistency between predictions and experiments via comparison of Figure 3 with Figure 4.

Overall, our impression is that TFutils is a useful package albeit for a restricted community of users already familiar with the other Bioconductor packages mentioned in the article. However, the manuscript could benefit from major revisions as pointed out above.

Is the rationale for developing the new software tool clearly explained?
Yes

Is the description of the software tool technically sound?
Yes

Are sufficient details of the code, methods and analysis (if applicable) provided to allow replication of the software development and its use by others?
Partly

Is sufficient information provided to allow interpretation of the expected output datasets and any results generated using the tool?
Partly

Are the conclusions about the tool and its performance adequately supported by the findings presented in the article?
Partly

Competing Interests: No competing interests were disclosed.

Reviewer Expertise: Bioinformatics, Epigenetics, ChIP-seq, regulatory region annotation, motif analysis, database design, web tools.

We confirm that we have read this submission and believe that we have an appropriate level
of expertise to confirm that it is of an acceptable scientific standard, however we have significant reservations, as outlined above.

Author Response 08 May 2019

Vincent Carey, Brigham and Women's Hospital, Harvard Medical School, Boston, USA

We are very appreciative of the effort underlying this review. Important questions were raised and we endeavor to answer them fully below. Reviewer comments are prefaced by "QUERY" and our replies are prefaced by "RESPONSE".

QUERY: This article looks more like a software tutorial than a scientific article. As software has to evolve in order keep up with user needs, the text will have to be updated on a regular basis in the future, in order to remain up-to-date as well. This is fine if F1000Research accepts updates and supports versioning of articles. Otherwise, another format should be chosen for presenting this tool.

RESPONSE: Because F1000Research accepts updates and supports versioning of articles, we believe that this format is an acceptable one for the work we have described.

QUERY: Just by reading the article, we didn't get a clear impression of what is inside TFutils. Going through the command examples was helpful in this respect. Nevertheless, we have doubts whether we would be able to use this package in a productive manner in the future. The promise that "TFutils lowers the barriers of usage of key findings of TF biology" holds only for expert users of Bioconductor, who are already familiar with all the other packages mentioned in this article and necessary to reproduce the results.

RESPONSE: We are glad that the examples in the paper were useful to the reviewer. It is true that Bioconductor software generally requires acquaintance with and use of multiple interrelated packages. In this sense, it is different from a relatively common approach of command-line utility implementation of bioinformatic analysis tools, where a given tool may be understood and used in isolation. We do not agree that "expert" level of understanding of Bioconductor is necessary to make use of the material described, although some facility with and enthusiasm for the R language would be necessary to make headway. The paper is published in the Bioconductor channel of F1000research, and it is expected that the readership will have an acquaintance with the resources and limitations of the Bioconductor software and data ecosystem.

QUERY: The current manuscript has several shortcomings. At a general level, it is not very transparent to the naïve reader what is actually new from this package and what functionalities are provided by the many other Bioconductor packages referred to in the text. Fortunately, we found a well-organized reference manual for TFutils version 1.2.0 on the internet, which clarified this issue for us. A URL to this document should have been included in the article.

RESPONSE: This is a useful observation. We have now included a reference to http://bioconductor.org/packages/release/bioc/manuals/TFutils/man/TFutils.pdf in the implementation section of the paper.
**QUERY:** As this is a tutorial-style document, it would be helpful to provide complete R code for reproducing Figures 3 and 4. While Figure 3 is relatively easy to generate, it took us at least half a day to reproduce Figure 4. A major limitation is that the fimo16 object, upon which Figure 3 is based, contains only TF affinity data for 16 out of 689 scanned TF motif matrices.

**RESPONSE:** We appreciate the effort taken here. The production of Figure 4 was complicated and we have created an app and associated github repository to clarify the basic issues. The repository is https://github.com/vjcitn/encdemo and the face page of the repo has a screenshot of the app, which runs at https://vjcitn.shinyapps.io/encdemo/. Our point in the visualization of Figure 4 is not the visualization per se, which can be accomplished with standard genome browsers, with suitable commands. Rather, we use the visualization to give concrete demonstration of the immediate programmatic availability (to users of this package) of the relevant experimental results and annotations. We concur that the limitation of fimo16 to a small number of TFs is disappointing. Comprehensive presentation of the scan scores to our user base/readership would require computational resources that we have not yet been able to muster. A local deployment requires close to a terabyte of indexed storage.

**QUERY:** Figure 3 shows the predicted binding sites for 16 TFs in a selected genomic region. Already with such a small number of TFs, the Figure is pretty crowded with dots. One wonders what it would look like if all 689 FIMO-scanned motif matrices were considered. In view of the density of motif matches it seems doubtful whether any biological insights can be gained from such a plot. Some guidance for the interpretation is needed.

**RESPONSE:** As noted just above we do not have a mechanism for providing all 689 scans. We have added text after Figure 3 acknowledging the challenge of interpretation, specifically with respect to combinatorics of TF binding.

**QUERY:** Figure 4 shows ENCODE binding peaks for CEBPB in the same genomic region that was used for Figure 3. Naturally, we were curious to know whether the peaks seen in this Figures co-localize with corresponding motif matches in Figure 3. Unfortunately, CEBPB is not included in the fimo16 collection. To exemplify the power of the tool, it would have been preferable to choose an example where the reader can crosscheck the consistency between predictions and experiments via comparison of Figure 3 with Figure 4.

**RESPONSE:** We agree that unification of concepts underlying Figure 3 and 4 would be quite desirable. Figure 3 is based on the analysis of motifs in reference sequence, while Figure 4 is a severe reduction of cell-type specific information from in vitro experiments. The data underlying the encdemo app noted above should be useful for beginning surveys across TFs and across cell types essential for a full understanding of cell-type specific combinatorics of TF binding.

**QUERY:** Overall, our impression is that TFutils is a useful package albeit for a restricted community of users already familiar with the other Bioconductor packages mentioned in the article. However, the manuscript could benefit from major revisions as pointed out
above.

**RESPONSE:** We appreciate the effort taken in this review and we have endeavored to answer the questions raised.

**Competing Interests:** None.

The TFutils package provides useful, convenient, integrated data structures for TF-related bioinformatics analyses, by incorporating the basic information of human transcription factors (TFs), such as TF classification, known TF targets, genome-wide TF binding sites and binding affinity scores, which might be used to prioritize candidate genetic variants and help understand gene transcriptional regulatory mechanisms. Importantly, it also provides an interactive interface to query TFs and TF targets implicated in human traits as discovered by many GWASs.

In a quick test, all demo code in this paper worked. However, to make sure TFutils is more useful to the bioinformatics community, a few questions may need to be addressed. Here are our detailed comments and questions.

1. TFutils includes resources from CISBP, HOCOMOCO, GO and MSigDb. There are additional human TF resources. Is there any reason not to include those resources such as JASPAR¹, Transfac², HDPI³ and uniPro⁴?

2. There are potential packages that will likely import TFutils such as TFBSTools for the analysis of transcription factor binding sites manipulation, motifStack for graphic representation of multiple motifs⁵ and MotIV. It will be helpful to present a few lines of code to show how to integrate data from TFutils to aforementioned pipelines.

3. The section “Basic concepts of transcription factor bioinformatics” includes lots of background information, such as existing TF-related data sources/bases, TF classification, and how TFutils incorporates and access those resources. To make it easy to follow, we suggest break this part into the Introduction section and the Method section. The author
may move the background information and TF classification to the Introduction section, and include an Implementation section in the Methods section to describe how TFutils incorporates all these data sources and how to retrieve the relevant information in TFutils and how to integrate with other packages as mentioned in 2, where the R script snippets can be displayed.

4. To maintain/increase the user base, it is important to keep the data up to date. Currently, the data were snapshots of the CISBP and HOCOMOCO catalogs. If the resources are not updated regularly, it's unlikely that users will use TFutils after 2-3 years. Is there a plan in place to have the resources assembled by TFutils be update regularly? How often is the update going to be? Is it going to be automatic or manually?

5. Flexibility of the data structure is also important, as users may want to expand the utility of TFutils. Suggest authors describe how to add features to the current data structures in TFutils in the manuscript.

6. It will be useful to add information on the numbers of TFs and targets included in the assembled resources, as well as in the original databases.

7. There is a python package having the same name “tfutils” which is very popular. If it is not too hard to do, we suggest authors change the package name to avoid confusion

8. Installation and running environments of the TFutils was described twice, once in the Introduction section, the other time in the Methods section: Operation: Installation. It is better to only describe this once in the Methods section.

9. There are many short paragraphs consisting of one or two sentences and related information are scattered into different sections. For instances, the last paragraph of the Introduction section about the limitations of TFutil might be moved to the Discussion part; whereas the third paragraph in the Discussion section might be moved to somewhere at the beginning of the Introduction section or where it is appropriate.

10. Page 6, the Summary section might be better moved to between the data availability section and the discussion section to summarize the implemented functionality of TFutil.

Besides those major issues, we also have a few minor questions:

1. Currently the abstract only mentions TF targets derived from the MSigDb. Considering that the ENCODE TF ChIP-seq data is one of the most significant resources for TF targets information as mentioned in the main text, suggest authors add how the ENCODE ChIP-seq data were incorporated into TFutils in the abstract.

2. Page 5, please clarify the type of details in the sentence “Full details are provided in Sonawane et al”.

3. Gene structure can be better depicted in Fig. 3 and Fig. 4, perhaps adopting the gene structure visualization in most genome viewers, showing exon/intron structure and gene transcription direction.

4. Please include the used R packages in the citation.

5. “TFtargs()” in Figure 5 legend needs to be edited.

6. For the subtitles under the Use cases section, suggest add find before “TFs that are direct GWAS ...” and retrieve before “Traits mapped to genes that ...”.

**Is the rationale for developing the new software tool clearly explained?**
Yes

**Is the description of the software tool technically sound?**
Yes

**Are sufficient details of the code, methods and analysis (if applicable) provided to allow replication of the software development and its use by others?**
Partly

**Is sufficient information provided to allow interpretation of the expected output datasets and any results generated using the tool?**
Yes

**Are the conclusions about the tool and its performance adequately supported by the findings presented in the article?**
Yes

**Competing Interests:** No competing interests were disclosed.

**Reviewer Expertise:** Bioinformatics, ChIP-seq, CRISPR technology, RNA-seq, annotation, ATAC-seq, motif analysis, shRNA/CRISPR screening, visualization, machine learning and database application

We confirm that we have read this submission and believe that we have an appropriate level of expertise to confirm that it is of an acceptable scientific standard, however we have significant reservations, as outlined above.

---

Author Response 08 May 2019

**Vincent Carey,** Brigham and Women's Hospital, Harvard Medical School, Boston, USA

We appreciate the careful reading of this paper, which has inspired additional functionality that will be added to the package. Reviewer comments (isolated with QUERY: tag) are addressed below (with RESPONSE: tag).

**QUERY:** TFutils includes resources from CISBP, HOCOMOCO, GO and MSigDb. There are additional human
TF resources. Is there any reason not to include those resources such as JASPAR1, Transfac2, HDPI3 and uniPro4?

**RESPONSE:** According to [http://cisbp.ccbr.utoronto.ca/summary.php?by=4&orderby=MSource_Identifier](http://cisbp.ccbr.utoronto.ca/summary.php?by=4&orderby=MSource_Identifier) JASPAR and TRANSFAC entries are included in CIS-BP. UniProbe is an interesting resource but does not provide a mapping from TF or motif to target genes. Interfacing to UniProbe is beyond the scope of the tasks intended for this paper. The same issue appears to us to apply to hPDI. Resources that do not enumerate "gene level" TF targets are beyond the scope of current work.

**QUERY:** There are potential packages that will likely import TFutils such as TFBSTools for the analysis of transcription factor binding sites manipulation, motifStack for graphic representation of multiple motifs5 and MotIV. It will be helpful to present a few lines of code to show how to integrate data from TFutils to aforementioned pipelines.

**RESPONSE:** We will add an example of how diversity in TF reference motif data leads to a structure that may be visualized with MotifDb/motifStack. Specifically the 1.5.x+ versions of TFutils will include a function that uses motifStack and MotifDb to generate displays like Figure 5 of the revised paper. This is the result of example(tffamCirc.plot)in the current deel branch of TFutils.

**QUERY:** The section “Basic concepts of transcription factor bioinformatics” includes lots of background information, such as existing TF-related data sources/bases, TF classification, and how TFutils incorporates and access those resources. To make it easy to follow, we suggest break this part into the Introduction section and the Method section. The author may move the background information and TF classification to the Introduction section, and include an Implementation section in the Methods section to describe how TFutils incorporates all these data sources and how to retrieve the relevant information in TFutils and how to integrate with other packages as mentioned in 2, where the R script snippets can be displayed.

**RESPONSE:** Some of these changes are made. Our approach to the narrative attempts to follow the F1000Research schema.

**QUERY:** To maintain/increase the user base, it is important to keep the data up to date. Currently, the data were snapshots of the CISBP and HOCOMOCO catalogs. If the resources are not updated regularly, it’s unlikely that users will use TFutils after 2-3 years. Is there a plan in place to have the resources assembled by TFutils be update regularly? How often is the update going to be? Is it going to be automatic or manually?

**RESPONSE:** The package will be updated according to the Bioconductor release protocol. The main pages give explicit information on provenance of information underlying serialized data structures. Community input on the utility of the various sources will be important in determining the frequency of content updates.

**QUERY:** Flexibility of the data structure is also important, as users may want to expand the
utility of TFutils. Suggest authors describe how to add features to the current data structures in TFutils in the manuscript.

**RESPONSE:** The code is open source. Pull requests are welcome. If there are specific features of interest to the reviewers we will consider how to incorporate them in future versions of the package/manuscript.

**QUERY:** It will be useful to add information on the numbers of TFs and targets included in the assembled resources, as well as in the original databases.

**RESPONSE:** Totals are added in the caption of Figure 1.

**QUERY:** There is a python package having the same name “tfutils” which is very popular. If it is not too hard to do, we suggest authors change the package name to avoid confusion.

**RESPONSE:** The python package addresses “tensorflow”, which is not related to TFs in bioinformatics. We do not believe that the risk of confusion is high, but will consider renaming if events of confusion are observed.

**QUERY:** Installation and running environments of the TFutils was described twice, once in the Introduction section, the other time in the Methods section: Operation: Installation. It is better to only describe this once in the Methods section.

**RESPONSE:** The presentation follows the suggested F1000Research format.

**QUERY:** There are many short paragraphs consisting of one or two sentences and related information are scattered into different sections. For instances, the last paragraph of the Introduction section about the limitations of TFutil might be moved to the Discussion part; whereas the third paragraph in the Discussion section might be moved to somewhere at the beginning of the Introduction section or where it is appropriate. Page 6, the Summary section might be better moved to between the data availability section and the discussion section to summarize the implemented functionality of TFutil.

**RESPONSE:** The last paragraph of the introduction is used to pre-empt potential reader disappointment early in the presentation, so we prefer to leave it where it is. The third paragraph in the discussion does include content of general and possibly introductory significance, but that content is embedded in concrete illustrations that depend upon actual details of package use. The "summary" element is provided to give the reader a break before plunging into the obligatory Methods/Implementation material. We concur with your basic aesthetic preferences but have organized our text in what we consider to be a rational way.

**QUERY:** Besides those major issues, we also have a few minor questions:

**QUERY:** Currently the abstract only mentions TF targets derived from the MSigDb. Considering that the ENCODE TF ChIP-seq data is one of the most significant resources for TF targets information as mentioned in the main text, suggest authors add how the
ENCODE ChIP-seq data were incorporated into TFutils in the abstract.

**RESPONSE:** metadata(encode690) provides details. The ENCODE data are derived from Bioconductor's AnnotationHub package. These facts are noted in the vicinity of Figure 4. We have added a phrase to the abstract that mentions the ENCODE interface.

**QUERY:** Page 5, please clarify the type of details in the sentence “Full details are provided in Sonawane et al”.

**RESPONSE:** These authors describe how FIMO was used to obtain sequence-based binding affinity scores; the main text is slightly modified to clarify the role of this reference.

**QUERY:** Gene structure can be better depicted in Fig. 3 and Fig. 4, perhaps adopting the gene structure visualization in most genome viewers, showing exon/intron structure and gene transcription direction.

**RESPONSE:** We agree that the gene model displays are sub-optimal. However, the visualizations are not central to the package. Ideally, Gviz, ggbio, or karyploter infrastructure would be used and we will pursue these improvements in updates to the package. Further discussion of the visualization is conducted with the other referee report. We note that the interactive “app” at https://vjcitn.shinyapps.io/encdemo/ can be used to interactively view binding sites for a small number of TFs in a small number of cell types. Such visualizations can be better accomplished with standard genome browsers. The visualizations in the paper are provided to make concrete the immediate programmatic availability of these resources and concepts to package users. In particular, Figure 3 just scratches the surface of the concept that the combinatorics of TF binding are complex. As noted by the other reviewer, the display is impossible to parse meaningfully in detail, but the overall interpretation is that binding events form a complex ensemble and that data structures and programming patterns are needed to develop compelling interpretations.

**QUERY:** Please include the used R packages in the citation.

**RESPONSE:** After running the Rmarkdown document in TFutils/vignette/TFutils_f1000 that conducts all the computations presented in the paper, sessionInfo() can be run to enumerate all packages in use. There are 37 packages attached, and 60 loaded but not attached. It does not seem reasonable to burden the paper with such an accounting. Users can run sessionInfo() and then query the DESCRIPTION files of packages of interest for provenance information.

**QUERY:** “TFtargs()” in Figure 5 legend needs to be edited.

**RESPONSE:** Done.

**QUERY:** For the subtitles under the Use cases section, suggest add find before “TFs that are direct GWAS ...” and retrieve before “Traits mapped to genes that ...”.

**RESPONSE:** Done.
Competing Interests: No competing interests were disclosed.

The benefits of publishing with F1000Research:

- Your article is published within days, with no editorial bias
- You can publish traditional articles, null/negative results, case reports, data notes and more
- The peer review process is transparent and collaborative
- Your article is indexed in PubMed after passing peer review
- Dedicated customer support at every stage

For pre-submission enquiries, contact research@f1000.com
