CATEGORIZATION OF WEDDERBURN’S
BASIS FOR \(\mathbb{C}[S_n]\)

VOLODYMYR MAZORCHUK AND CATHARINA STROPEL

Abstract. M. Neunhöffer studies in [Ne] a certain basis of \(\mathbb{C}[S_n]\) with
the origins in [Lu] and shows that this basis is in fact Wedderburn’s
basis, hence decomposes the right regular representation of \(S_n\) into a
direct sum of irreducible representations (i.e. Specht or cell modules).
In the present paper we rediscover essentially the same basis with a
categorical origin coming from projective-injective modules in certain
subcategories of the BGG-category \(\mathcal{O}\). Inside each of these categories,
there is a dominant projective module which plays a crucial role in our
arguments and will additionally be used to show that Kostant’s problem
([Jo]) has a negative answer for some simple highest weight module over
the Lie algebra \(\mathfrak{sl}_4\). This disproves the general belief that Kostant’s
problem should have a positive answer for all simple highest weight
modules in type \(A\).

1. The main result

Let \(n\) be a positive integer and \(S_n\) the group of permutations of the elements
from \(\{1,2,\ldots,n\}\). Denote by \(\mathcal{S}\) the usual set of Coxeter generators
of \(S_n\) and by \(\mathcal{H} = \mathcal{H}(S_n,\mathcal{S})\) the associated (generic) Iwahori-Hecke algebra. The algebra \(\mathcal{H}\) is a free \(\mathbb{Z}[v,v^{-1}]\)-module with basis \(\{H_w | w \in S_n\}\) and
multiplication given by
\[
H_x H_y = H_{xy} \quad \text{if} \quad l(x) + l(y) = l(xy)
\]
and \(H_s^2 = H_e + (v^{-1} - v)H_s\) for \(s \in S\),
where \(l : S_n \to \mathbb{Z}\) denotes the length function with respect to \(\mathcal{S}\). Denote by \(\{H_w | w \in S_n\}\) the
Kazhdan-Lusztig basis (in the normalization of [So]). We
also denote by \(\{\hat{H}_w | w \in S_n\}\) the dual Kazhdan-Lusztig basis of \(\mathcal{H}\), defined
via \(\tau(\hat{H}_v H_w - 1) = \delta_{v,w}\), where \(\tau\) is the standard symmetrizing trace form.

The group algebra \(\mathbb{C}[S_n]\) of \(S_n\) is obtained by specializing \(v\) to \(1\) in \(\mathcal{H}\),
more precisely: by extending first the scalars in \(\mathcal{H}\) to \(\mathbb{C}\) and then factoring
out the ideal generated by \(v - 1\) we get an epimorphism of \(\mathbb{C}\)-algebras, which
we call the evaluation map:
\[
ev : \mathbb{C} \otimes \mathcal{H} \to \mathbb{C} \otimes \mathcal{H} / (v - 1) \to \mathbb{C}[S_n], \quad 1 \otimes H_w \mapsto w.
\]

The Robinson-Schensted correspondence (see e.g. [Sa, 3.1]) defines a bi-
jection between elements \(w \in S_n\) and pairs \((a(w), b(w))\) of standard tableaux

Sciences, and the Swedish Research Council, the second author by EPSRC.

1
with \( n \) boxes, such that \( a(w) \) and \( b(w) \) are of the same shape. For every element \( w \in S_n \) we denote by \( R_w = \{ x \in S_n \mid a(x) = a(w) \} \) the right cell of \( S_n \) which contains \( w \). Let \( \overline{w} \) denote the unique involution in \( R_w \). Beside \( a(\overline{w}) = a(w) \) the element \( \overline{w} \) satisfies (and is characterized by the property) \( a(\overline{w}) = b(\overline{w}) \). It is the Duflo involution of \( R_w \).

Our main result is the construction of a basis \( \{ f_w \mid w \in S_n \} \) of \( \mathbb{C}[S_n] \) compatible with its regular right \( S_n \)-module structure in the following way:

**Theorem 1.** For \( w \in S_n \) set \( f_w = \text{ev}((\overline{H}_x \cdot \overline{H}_w)) \). Then the following holds:

(a) The elements \( \{ f_w \mid w \in S_n \} \) form a basis of \( \mathbb{C}[S_n] \).

(b) Let \( x \in S_n \) and consider the linear span \( S(x) \) of all \( f_w, w \in R_x \). Then \( S(x) \) is invariant with respect to the right action of \( \mathbb{C}[S_n] \) and isomorphic to the (irreducible) cell module associated with \( R_x \).

In other words, there is a decomposition of the right regular representation of \( S_n \) into a direct sum of irreducible modules which is compatible with the basis \( \{ f_w \mid w \in S_n \} \). In fact the theorem and its proof are valid over any field of characteristic zero. As an example, for \( n = 3 \) let \( s \) and \( t \) be the simple reflections, then our basis consists of the elements

\[
\begin{align*}
f_e &= (e - s - t + st + ts - st) e = e - s - t + st + ts - st, \\
f_s &= (s - ts - st + st) (s + e) = e + s - t - ts, \\
f_t &= (t - ts - st + st) (t + e) = e + t - s - st, \\
f_{st} &= (s - ts - st + st) (st + s + t + e) = s + st - ts - st, \\
f_{ts} &= (t - ts - st + st) (ts + s + t + e) = t + ts - st - st, \\
f_{sts} &= st (e + t + s + st + ts + st) = e + t + s + st + ts + st.
\end{align*}
\]

Unfortunately, this method does not give a basis for the algebra \( \mathcal{H} \).

Theorem 1 turns out to be related to the paper [Ne], where a similar basis was studied. Let \( \{ R_i : i \in I \} \) be a set of right cells in \( S_n \) containing exactly one representative of each two-sided cell. For each \( i \in I \) and \( (x, y) \in R_i \times R_i \) set \( h_{(x,y)}^i = \text{ev}((\overline{H}_x \cdot \overline{H}_y)). \) From [Ne] it follows that \( \{ h_{(x,y)}^i : i \in I, (x, y) \in R_i \times R_i \} \) has properties analogous to those of the basis \( \{ f_w \mid w \in S_n \} \) from Theorem 1. Moreover, in [Ne] it is even proved that a normalized version of \( \{ h_{(x,y)}^i \mid i \in I, (x, y) \in R_i \times R_i \} \) is in fact Wedderburn’s basis of \( \mathbb{C}[S_n] \) (i.e. basis elements correspond to matrix units in Wedderburn’s decomposition of \( \mathbb{C}[S_n] \)). The origins of the basis \( \{ h_{(x,y)}^i \mid i \in I, (x, y) \in R_i \times R_i \} \) go further back to [Lu]. There is an asymptotic version \( J \) of the Hecke algebra, introduced by Lusztig in [Lu] together with a homomorphism \( \Psi : \mathcal{H} \to \mathbb{Z}[v, v^{-1}] \otimes_{\mathbb{Z}} J \) which becomes an isomorphism over \( \mathbb{Q}(t) \). As pointed out to us by Neunhöffer, the basis \( \{ h_{(x,y)}^i \mid i \in I, (x, y) \in R_i \times R_i \} \) is exactly Lusztig’s basis for \( J \) pulled back via the homomorphism \( \Psi \) to \( \mathcal{H} \). The connection to [Ne] is the following:

**Theorem 2.** \( \{ f_w \mid w \in S_n \} = \{ h_{(x,y)}^i \mid i \in I, (x, y) \in R_i \times R_i \} \).
The origins of Theorem 1 as well as the proof of Theorem 2 are categorical; and this is absolutely crucial for our arguments. In particular, our setup is completely different from the combinatorial approach of [Ne]. There are alternative combinatorial approaches to the construction of a basis for $C[S_n]$ and some related algebras in which the regular representation decomposes into a direct sum of irreducibles, see [RW], [Mu1], [Mu2], [Mat1], [Mat2]. There are also alternative combinatorial constructions (e.g. [KL], [Al1], [Al2]) giving decompositions of the regular representation of $S_n$ into irreducible representations using an explicit basis, which lead only to filtrations whose successive subquotients are irreducible.

**Acknowledgment.** We thank Ken Brown for suggestions, Meinfold Geck for information about [Ne], and Michael Rapoport for helpful discussions. We also thank Max Neunhöffer, Susumu Ariki and Andrew Mathas for remarks on a preliminary version of the paper. Finally, we thank the referee for very useful comments and suggestions.

## 2. Proof of Theorem 1

We prove Theorem 1 by giving an explicit categorical interpretation of all ingredients, which is based on the categorification of cell modules as established in [MS, Section 4] (the original idea of categorifying the Hecke algebra goes back to [KL] and [BG]). The main players here are certain subquotient categories of the famous BGG category $\mathcal{O}$ (for the latter see [BGG]).

Let $\mathcal{O}_0$ be the principal block of $\mathcal{O}$ for the simple complex Lie algebra $\mathfrak{sl}_n$ with its standard triangular decomposition. The simple objects in $\mathcal{O}_0$ are the $L(w)$, $w \in S_n$, the simple highest weight modules with the highest weight $w(\rho) - \rho$, where $\rho$ is the half-sum of all positive roots. Let $\Delta(w)$ and $P(w)$ denote the Verma and the indecomposable projective module with unique simple quotient isomorphic to $L(w)$ respectively. Further, denote by $\theta_w$ the indecomposable projective endofunctor of $\mathcal{O}_0$ with the property $\theta_w P(e) \cong \theta_w \Delta(e) \cong P(w)$ (see [BG]). Finally, let $[\mathcal{O}_0]$ denote the complexified Grothendieck group of $\mathcal{O}_0$. For $M \in \mathcal{O}_0$ we denote by $[M]$ its image in $[\mathcal{O}_0]$.

There is a $\mathbb{C}$-linear isomorphism $\varphi : [\mathcal{O}_0] \to \mathbb{C}[S_n]$ with $\varphi([\Delta(w)]) = w$. The Kazhdan-Lusztig conjecture ([KL], proved in [BeBe], [BK]) implies that $\varphi([P(w)]) = \text{ev}(\hat{H}_w)$ (for an overview see e.g. [MS, Subsection 3.4]). The standard bilinear form on $\mathbb{C}[S_n]$ is categorified via the bifunctor $\text{Ext}^*(\_ , \_ )$ ([KMS, Section 5] or [MS, Subsection 4.6]). Indecomposable projective and simple modules form dual bases with respect to this form, and hence

\begin{equation}
\varphi([L(w)]) = \text{ev}(\hat{H}_w)
\end{equation}
The functors $\theta_w$ are exact and induce therefore $\mathbb{C}$-linear endomorphisms $[\theta_w]$ of $[O_0]$. By [BG, Theorem 3.4(iv)] and [SGI] (for a more adjusted reformulation see [KMS, Subsection 3.4]) we have

$$\varphi([\theta_w M]) = \varphi([\theta_w][M]) = \varphi([M]) \text{ev}(H_w).$$

(2.2) for all $M$ in $O_0$. Recall the right cells mentioned above and let $\leq R$ be the right preorder on $S_n$. Fix $w \in W$ and set $\hat{R}_w = \{x \in S_n | x \leq_R y \text{ for some } y \in \hat{R}_w\}$. Associated with the right cell $\hat{R}_w$ of $w$ we have the full subcategory $O^\hat{R}_w$ of $O_0$, which consists of all modules $M$ with all composition subquotients of the form $L(x)$ with $x \in \hat{R}_w$. Let $Z^\hat{R}_w : O_0 \rightarrow O^\hat{R}_w$ be the natural projection functor which takes the maximal quotient that lies in $O^\hat{R}_w$. All this is built up such that we have

$$Z^\hat{R}_w \theta_x \cong \theta_x Z^\hat{R}_w$$

(2.3) for any $x, w \in S_n$, ([MS, Lemma 19]). For $x \in S_n$ we define $P^\hat{R}_w(x) = Z^\hat{R}_w P(x)$, and it follows that

$$P(x) \neq 0 \text{ if and only if } x \in \hat{R}_w.$$ (2.4)

Moreover, the set $\{P^\hat{R}_w(x) | x \in \hat{R}_w\}$ constitutes a complete list of indecomposable projective modules in $O^\hat{R}_w$.

The following provides a basis of $\mathbb{C}[S_n]$ with most of the desired properties:

**Proposition 3.** For $w \in S_n$ define $g_w = \varphi([P^\hat{R}_w(w)]) \in \mathbb{C}[S_n]$. Then the following holds:

(a) $\{g_w | w \in S_n\}$ is a basis of $\mathbb{C}[S_n]$.

(b) For every $x \in S_n$ the linear span of $\{g_w | w \in \hat{R}_x\}$ is invariant with respect to the right action of $S_n$ and is isomorphic to the cell module associated with $\hat{R}_x$.

**Proof.** As $|\{g_w | w \in S_n\}| = |S_n| = \text{dim}_\mathbb{C} \mathbb{C}[S_n]$, it is enough to show that the elements from $\{g_w | w \in S_n\}$ are linearly independent. By definition of the category $O^\hat{R}_w$, all the simple composition factors of $P^\hat{R}_w(w)$ are of the form $L(z)$ where $z$ is smaller or equal to $x$ in the right cell order. Therefore, when expressed in the specialization $\{\text{ev}(H_z) | z \in S_n\}$ of the dual Kazhdan-Lusztig basis, the element $g_w$ is a linear combination of basis elements, corresponding to $z \in \hat{R}_x$ (see (2.1)). By induction on the right order, it is then enough to show that for any $x \in S_n$ the elements from $\{g_w | w \in \hat{R}_x\}$ are linearly independent. By [KMS, Theorem 1] and [MS, Theorem 18], these elements form the Kazhdan-Lusztig basis in the cell module associated with $\hat{R}_x$. The cell module is a subquotient of $\mathbb{C}[S_n]$. Hence these elements are linearly independent already in $\mathbb{C}[S_n]$. The first statement follows.

To prove the invariance it is enough to show, thanks to (2.2), that projective functors preserve the additive subcategory $\mathcal{A}$ of $O^\hat{R}_w$ generated by the indecomposable projective modules $P^\hat{R}_w(w), w \in \hat{R}_x$. Since $\mathcal{H}$ is generated
by the $H_w$, where $s$ runs through $S$, it is enough to show that for any $s \in S$ and $w \in R_x$ the module $\theta_s P^{\hat{R}_w}(w)$ belongs to $\mathcal{A}$. Now (2.3), [MS (4.1)] and (2.4) provide the following three isomorphisms:

\begin{align*}
\theta_s P^{\hat{R}_w}(w) &= \theta_s Z^{\hat{R}_w} \theta_y \Delta(e) \\
&\cong Z^{\hat{R}_w} \theta_y \theta^{\hat{R}_w} \Delta(e) \\
&\cong Z^{\hat{R}_w} \left( \oplus_{y \geq a} \theta^{\hat{R}_w} \Delta(e) \right) = \oplus_{y \geq a} \left( Z^{\hat{R}_w} P(y) \right)^{\oplus m_y} \\
&\cong \oplus_{y \in R_x} \oplus_{l=1}^{m_y} P^{\hat{R}_w}(y)
\end{align*}

for some non-negative integers $m_y$. The claim about the invariance follows. The claim about the cell module follows from [MS Theorem 16 and Theorem 18].

Now Theorem follows from the following statement:

**Proposition 4.** We have $f_w = g_w$ for all $w \in S_n$. In particular, Theorem follows from Proposition 3.

**Proof.** We already know that $\varphi([L(w)]) = ev(\hat{H}_w)$ for all $w \in S_n$. Thanks to (2.2) and the definitions of $f_w$ and $g_w$, the proposition is implied by the

**Key statement:** Let $w \in S_n$, then $\theta_{y} P^{\hat{R}_w}(w) \cong P^{\hat{R}_w}(w)$

which also explains the categorical meaning of the basis. In what follows we prove this statement.

Recall that $P^{\hat{R}_w}(w) \cong \theta_y P^{\hat{R}_w}(e)$ by (2.3). To prove the key statement we have to study the dominant projective module $P^{\hat{R}_w}(e)$ in $O^{\hat{R}_w}$ in more detail.

**Lemma 5.** Let $x \in R_w$ be such that $x \neq \overline{x}$. Then $[P^{\hat{R}_w}(e) : L(x)] = 0$.

**Proof.** Recall that the functor $\theta_x$ is both left and right adjoint to the functor $\theta_{x-1}$. Hence we have

\begin{align*}
[P^{\hat{R}_w}(e) : L(x)] &= \dim \text{Hom}_{O}(P^{\hat{R}_w}(x), P^{\hat{R}_w}(e)) \\
&= \dim \text{Hom}_{O}(P^{\hat{R}_w}(e), P^{\hat{R}_w}(x)) \\
&= \dim \text{Hom}_{O}(P^{\hat{R}_w}(e), \theta_{x-1} P^{\hat{R}_w}(e)).
\end{align*}

As $x \neq \overline{x}$, we have $x \neq x^{-1}$, and hence, using [Sa, Theorem 3.6.6], we have $a(x^{-1}) = b(x) \neq a(x)$. Thus $x^{-1} \not\in R_w$. Since $a(x^{-1})$ and $a(x)$ still have the same shape, it follows that $x^{-1} \not\in R_w$ ([BjBr, Exercise 10, page 198]). Therefore $\theta_{x-1} P^{\hat{R}_w}(e) = \theta_{x-1} Z^{\hat{R}_w} \Delta(e) \cong Z^{\hat{R}_w} P(x^{-1}) = 0$ and thus $\dim \text{Hom}_{O}(P^{\hat{R}_w}(e), \theta_{x-1} P^{\hat{R}_w}(e)) = 0$ as well. \hfill $\Box$

**Lemma 6.** For any $x \in R_w$ and $y \in \hat{R}_w \setminus R_w$ we have $\theta_x L(y) = 0$. In particular, $[P^{\hat{R}_w}(e) : L(\overline{y})] > 0$.

**Proof.** As $P^{\hat{R}_w}(y) \to L(y)$ and $\theta_x$ is exact, we have $\theta_x P^{\hat{R}_w}(y) \to \theta_x L(y)$.

Applying (2.3) we even have that $\theta_x L(y)$ is a homomorphic image of the module $Z^{\hat{R}_w} \theta_x \theta_y \Delta(e)$.
Note that $\theta_x L(y) \in O^R_w$, in particular, all simple subquotients of $\theta_x L(y)$ have the form $L(z)$, $z \in R_y$.

On the other hand, it follows from [MS (4.1)] that $\theta_x \theta_y$ is a direct sum of functors of the form $\theta_z$, where $z \geq_L x$. Hence, by (2.4), all simple quotients of the module $Z^R_w \theta_x \theta_y \Delta(e)$ have the form $L(x)$. As $x \not\in R_y$ by our choice of $y$, we must have $\theta_x L(y) = 0$. We know that $P^R_w(e) = \theta_{\overline{w}} P^R_w(e) \neq 0$. By Lemma 5 and the above, $L(\overline{w})$ is the only subquotient of $P^R_w(e)$ which has the chance not to be annihilated by $\theta_{\overline{w}}$. Altogether we must have $[P^R_w(e) : L(\overline{w})] > 0$ \hfill \Box

**Lemma 7.** $[P^R_w(e) : L(\overline{w})] = 1$.

**Proof.** Assume for a moment that $R_w$ contains an element of the form $w_0'w_0$, where $w_0$ is the longest element of $S_n$ and $w_0'$ is the longest element of some parabolic (Young) subgroup $W$ of $S_n$. Let $S$ be the set of simple reflections in $W$. Then the modules $P^R_w(x), x \in R_w$, are exactly the indecomposable projective-injective modules in the parabolic subcategory $O^S_0$ (in the sense of [R-C]) of $O_0$ (MS Remark 14)]. Amongst the indecomposable projective-injective modules in $O^S_0$ there is, due to [IS 3.1], a special one which is obtained as a translation of some simple projective module (out of possibly several walls). Since translation to walls maps simple modules to simples or zero, the special module, call it $P$, is thus obtained as a translation of some $L(x)$ for some $x \in R_w$.

From [KMS Theorem 1] it further follows that translating $P$ and taking appropriate direct summands, we will finally get all $P^R_w(x), x \in R_w$. This implies the existence of an indecomposable projective functor $\theta_y$ such that the module $\theta_y L(\overline{w})$ contains $P^R_w(\overline{w})$ as a direct summand (see [MS 5.1]). By [MS Theorem 18], the above restriction that the right cell should contain $w_0'w_0$ is in fact superfluous. Moreover, from [MS Theorem 18] it also follows that the module $P^R_w(\overline{w})$ is an injective object in $O^R_w$ (and so the same holds for any $P^R_w(x), x \in R_w$).

Consider now $\theta_y P^R_w(e) \cong P^R_w(y)$. As $P^R_w(\overline{w})$ is both projective and injective, from Lemma 6 it follows that $P^R_w(\overline{w})$ must be a direct summand of $P^R_w(y)$. As $P^R_w(y)$ is indecomposable, this forces $P^R_w(y) \cong P^R_w(\overline{w})$, $y = \overline{w}$, and finally $[P^R_w(e) : L(\overline{w})] = 1$. \hfill \Box

From Lemma 6 and Lemma 7 it follows that for any $x \in R_w$ we have $\theta_x P^R_w(e) \cong \theta_x L(\overline{w})$. This finally proves the key statement and at the same time completes the proof of Proposition 4 and Theorem 1 \hfill \Box

**Remark 8.** Let $w \in S_n$ be such that the right cell $R_w$ contains the element $w_0'w_0$ for some Young subgroup $W'$ of $S_n$. Then $O^R_w$ is the regular block of the parabolic category $O$ (in the sense of [R-C]) associated with $W'$. The elements $f_x, x \not\leq_R w$, form a basis of a submodule $N$ of $C[S_n]$. The quotient
\[ \mathbb{C}[S_n]/N \] is isomorphic to the induced sign module \( \mathbb{C}[S_n] \otimes_{\mathbb{C}[W]} \text{sign} \) (see [MS 6.2.1] for details) with the classes of the elements \( f_x, x \leq_R w \) forming a basis. Alternatively, the elements \( f_x, x \leq_R w \), form a basis of a submodule of \( \mathbb{C}[S_n] \) which is isomorphic to the induced sign module.

3. Proof of Theorem 2

Using (2.1) and (2.2) we interpret \( h^i_{(x,y)} = \varphi(\theta_y L(x^{-1})) \) for each \( i \in I \) and \( (x,y) \in R_i \times R_i \). Let \( i \in I \) be fixed. Because of Proposition 4 and the definition of \( g_w \)'s, to prove Theorem 2 it is enough to show that every \( \theta_y L(x^{-1}) \) is a projective-injective module in \( O_{\mathbb{R}^{-1}}^R \). In the case \( x = y \) this follows from the Key statement of Section 2.

Let now \( x \in R_i \) be arbitrary. As \( x \) and \( y \) belong to the same right cell, the elements \( x^{-1} \) and \( y \) belong to the same left cell. Let \( \mathcal{A} \) and \( \mathcal{B} \) denote the additive categories of projective-injective modules in \( O_{\mathbb{R}^+}^R \) and \( O_{\mathbb{R}^{-1}}^R \) respectively. In [MS Section 5] it was shown that there exists an equivalence \( F : \mathcal{A} \to \mathcal{B} \) which commutes with projective functors and satisfies \( F(P_{\mathbb{R}^+}(x)) = P_{\mathbb{R}^{-1}}(x) \).

Let \( \mathcal{A} \) and \( \mathcal{B} \) denote the full subcategories of respectively \( O_{\mathbb{R}^+}^R \) and \( O_{\mathbb{R}^{-1}}^R \) which consist of all modules \( X \) having a two step presentation \( M_1 \to M_0 \to X \to 0 \), where \( M_1, M_0 \in \mathcal{A} \) or \( M_1, M_0 \in \mathcal{B} \) respectively. Then \( F \) extends, in the obvious way, to an equivalence \( F : \mathcal{A} \to \mathcal{B} \) which commutes with projective functors.

Let \( L(x) \) denote the quotient of \( P_{\mathbb{R}^+}(x) \) modulo the trace of all modules from \( \mathcal{A} \) in the radical of \( P_{\mathbb{R}^+}(x) \). Define \( L(x^{-1}) \) analogously. Then \( L(x) \) has simple top \( L(x) \) and all other subquotients of \( L(x) \) are of the form \( L(z) \), where \( z < R x \). Analogously \( L(x^{-1}) \) has simple top \( L(x^{-1}) \) and all other subquotients of \( L(x^{-1}) \) are of the form \( L(z) \), where \( z < R x^{-1} \). From the above construction we have \( F(L(x)) = L(x^{-1}) \). Further \( \theta_y L(x) = \theta_y L(x^{-1}) \) by Lemma 6. Analogous arguments imply \( \theta_y L(x^{-1}) = \theta_y L(x^{-1}) \). Adding everything up we have

\[ \theta_y L(x^{-1}) = \theta_y L(x^{-1}) = \theta_y F(L(x)) = \theta_y F(L(x)) = F(\theta_y L(x)) = F(\theta_y L(x)). \]

Hence \( \theta_y L(x^{-1}) = F(\theta_y L(x)) \) is a projective-injective module in \( O_{\mathbb{R}^{-1}}^R \). The claim follows.

4. An application to Kostant’s problem

The core object \( \Delta_{\mathbb{R}_0}(e) \) of our study in Section 2 has an unexpected application to the so-called Kostant’s problem from [Jo]; see also [Ja, Kapitel 6].

Let \( g \) be a complex reductive finite-dimensional Lie algebra. For every \( g \)-module \( M \) we have the bimodule \( \mathcal{L}(M, M) \) of all \( \mathbb{C} \)-linear endomorphisms of \( M \) on which the adjoint action of the universal enveloping algebra \( U(g) \) is locally finite. (That means any vector \( f \in \mathcal{L}(M, M) \) lies inside a finite
dimensional subspace which is stable under the adjoint action defined as $x.f(m) = x(f(m)) - f(xm)$ for $x \in \mathfrak{g}$, $m \in M$. Initiated by [Jo], Kostant’s problem became the standard terminology for the following question concerning an arbitrary $\mathfrak{g}$-module $M$:

Is the natural injection $U(\mathfrak{g})/\text{Ann}(M) \rightarrow \mathcal{L}(M, M)$ surjective?

Although there are several classes of modules for which the answer is known to be positive (see [Jo], [Maz], [MS] and references therein), a complete answer to this problem seems to be far away - the problem is not even solved for simple highest weight modules. In [Jo, 9.5] an example of a simple highest weight module in type $B_2$ for which the answer is negative is mentioned (for details see [MS, 11.5]). In this section we use the module $\Delta_{\hat{w}}(e)$ to construct another example in type $A_3$, which disproves a general belief that the answer to Kostant’s problem is positive for simple highest weight modules in type $A$ (this belief was based on [Jo, 9.1] and further strengthened by [MS, Theorem 60]).

Let $n = 4$ and $r = (12)$, $s = (23)$, $t = (34)$ be the standard Coxeter generators of $S_4$. Consider $w = rt = \overline{w}$. In this case we have $R_w = \{rt, rts\}$ and $\hat{R}_w = \{rt, rts, t, ts, tsr, r, rs, rst, e\}$. We consider the graded version of $O$ as worked out in [St1]. Using [St2, Appendix] one computes that the module $N = \Delta_{\hat{w}}(e)$ has the following graded filtration (resp. socle or radical filtration), where we abbreviate $L(x)$ simply by $x$:

$$N = \begin{array}{c} e \\ r \\ t \\ rt \end{array}$$

**Lemma 9.** $\text{Ann}(L(rt)) = \text{Ann}(N)$

*Proof.* Let $Y_r$ and $Y_t$ denote some non-zero elements from the negative root spaces corresponding to $r$ and $t$ respectively. Let further $U'$ be the localization of $U(\mathfrak{sl}_4)$ with respect to the multiplicative set $\{Y_r^iY_t^j | i, j \geq 0\}$. As $rt > r$ and $rt > t$ with respect to the Bruhat order, both $Y_r$ and $Y_t$ act injectively on $L(rt)$. Hence $L(rt)$ will be the simple socle of the $\mathfrak{sl}_4$-module $N' = U' \otimes_{U(\mathfrak{sl}_4)} L(rt)$. As $t > e$ it is further easy to see (for example using the results of [KM, Section 4]) that $N$ is a submodule of $N'$. Hence the statement of the lemma would follow if we would prove that $\text{Ann}(L(rt)) = \text{Ann}(N')$. In fact, as $L(rt) \subset N'$, we have only to prove that $\text{Ann}(L(rt)) \subset \text{Ann}(N')$. This however, follows from the following statement:

**Lemma 10.** Let $\mathfrak{g}$ be a semi-simple finite-dimensional Lie algebra, $0 \neq x \in \mathfrak{g}$ some root vector, and $M$ a $\mathfrak{g}$-module on which $x$ acts injectively. Let $U'$ be the localization of $U(\mathfrak{g})$ with respect to the powers of $X$. Then $\text{Ann}(M) \subset \text{Ann}(M')$, where $M' = U' \otimes_{U(\mathfrak{g})} M$.

*Proof.* The set $X := \{x^i | i \geq 0\}$ is an Ore set in $U(\mathfrak{g})$ with $X \cap \text{Ann}(M) = \emptyset$ by hypothesis. So $U'\text{Ann}(M) = \text{Ann}(M)U'$ is a proper ideal in $U'$. This
means \( \text{Ann}(M)M' = \text{Ann}(M)U'M = U'\text{Ann}(M)M = \{0\} \). This completes the proof.

The proof of Lemma 9 is now complete.

**Lemma 11.** (a) The module \( \theta_t\theta_s\theta_rN \) has the following graded filtration:

\[
\begin{array}{cccccc}
\text{rst} & \text{rs} & \text{rt} \\
\text{rst} & \text{tsr} & \text{trs} & \text{r} \\
\text{rt} & & & & \\
\end{array}
\]

(b) The module \( \theta_t\theta_s\theta_rL(rt) \) is a submodule of the module \( \theta_t\theta_s\theta_rN \) and has the following graded filtration:

\[
\begin{array}{cccccc}
\text{rt} & \text{tsr} & \text{trs} & \text{r} \\
\text{rt} & & & & \\
\end{array}
\]

**Proof.** This is verified by direct computations.

**Theorem 12.** Kostant’s problem has a negative answer for \( L(rt) \).

**Proof.** As \( N \) is a quotient of the dominant Verma module, Kostant’s problem has a positive solution for \( N \) by [Ja, 6.9]. Hence \( \mathcal{L}(N, N) = U(\mathfrak{sl}_4)/\text{Ann}(N) \). By Lemma 9 we have \( \text{Ann}(N) = \text{Ann}(L(rt)) \) and hence we also have \( U(\mathfrak{sl}_4)/\text{Ann}(N) = U(\mathfrak{sl}_4)/\text{Ann}(L(rt)) \). From Lemma 11 we obtain that \( \dim \text{Hom}_\mathcal{O}(N, \theta_t\theta_s\theta_rN) = 0 \) (as for the top \( L(e) \) of \( N \) we have \( \theta_t\theta_s\theta_rN : L(e) \) = 0), while \( \dim \text{Hom}_\mathcal{O}(L(rt), \theta_t\theta_s\theta_rL(rt)) \neq 0 \) by Lemma 11 (as \( L(rt) \) obviously occurs in the socle of \( \theta_t\theta_s\theta_rL(rt) \)). This implies \( \mathcal{L}(N, N) \neq \mathcal{L}(L(rt), L(rt)) \), which, in turn, yields \( \mathcal{L}(L(rt), L(rt)) \neq U(\mathfrak{sl}_4)/\text{Ann}(L(rt)) \). The claim follows.
