Nilmanifolds and their associated non local fields

Juan J. Villarreal

December 5, 2018

Abstract

For some nilmanifolds we build a module $\mathcal{H}$ of an affine Kac Moody vertex algebras. Then, we associate some logarithmic fields for the module $\mathcal{H}$ and we study their singularities. We also presented a physics motivation behind this construction.

We study a particular case, we show that when the nilmanifold $N$ is a $k$ degree $S^1$–fibration over the two torus and a choice of $l \in \mathbb{Z} \cong H^3(N,\mathbb{Z})$ the fields associated to the space $\mathcal{H}$ have tri-logarithm singularities whenever $kl \neq 0$.

1 Introduction

Vertex algebras appeared in the early days of string theory, in this theory vertex algebras can be seen as the mathematical equivalent of chiral symmetry algebras in conformal field theory. Working the CFT interpretation in physics of sigma models, we can associate for some manifolds a vertex algebra. This interpretation turns out to be very restrictive, in particular, the manifolds must be flat manifolds\textsuperscript{1}. We can consider other interpretations to associate vertex algebras to manifolds, in [4] the authors considered a bracket for some fields that naturally lead to the Courant bracket or more generally considering additionally a closed three form, the twisted Courant bracket. In this case the bracket does not have dynamical information. In this work, we use vertex algebras to describe this bracket, we call this construction of vertex algebras the Hamiltonian formalism\textsuperscript{2}.

In [1] the authors studied from this point of view the algebras associated to the three dimensional Heisenberg nilmanifold, and to the three dimensional torus with a closed three form. These informations were used to build some 6 dimensional nilmanifolds, $M(1,0)$ and $M(0,1)$ respectively we explain this notation in section 3. The motivation behind the choise of these manifolds and three forms is a phenomenon in physics called T-duality, the 6 dimensional nilmanifolds also have a motivation from a physics theory called Double field theory [15].

In this work we consider a more general case, three dimensional Heisenberg nilmanifolds with closed three forms. In this case, we have more general 6 dimensional nilmanifolds $M(k,j)$. We explain the construction of these nilmanifolds in the section 3, the construction of these nilmanifolds from a physics point of view was given in [5]. Considering the Hamiltonian

\textsuperscript{1}If we work with super vertex algebras then the manifolds could be Calabi Yau manifolds, these restrictions are given by the beta equations in the physics literature, [17].

\textsuperscript{2}If we consider super vertex algebras, there is a construction called Chiral de Rham [18] which associate sheaves of super vertex algebras to any manifold. The Courant bracket also appear in this construction, there is an Hamiltonian interpretation of this construction in [16]
formalism for these more general manifolds, we generalize the algebras found in [1] as we now explain.

Before explain the algebraic construction associated to these six dimensional nilmanifolds, we set our notation for vertex algebras. We make a short physics introduction on the next section, now we express mathematically the algebraic construction.

In vertex algebras theory, some of the first examples we studied are Heisenberg vertex algebra and affine Kac Moody algebras. We can define these vertex algebras from finite dimensional Lie algebras $\mathfrak{h}$ endowed with a bi-invariant pairing. The space of states of these vertex algebras is given by the vector space\(^3\).

\[ V^1(\mathfrak{h}) = \text{Ind}_{\mathfrak{h}[t]}^{\hat{\mathfrak{h}}} |0\rangle = U(\hat{\mathfrak{h}}) \otimes U(\mathfrak{h}[t]) \otimes \mathbb{C} |0\rangle, \]

where $K$ acts as $K = 1Id$. The fields are defined as linear maps

\[ Y(., z) : V^1(\mathfrak{h}) \rightarrow \text{End}(V^1(\mathfrak{h}))[z, z^{-1}], \text{ s.t. } Y(a, z)b \in V^1(\mathfrak{h})(z). \]

In this work we consider six dimensional lie algebras $\mathfrak{h}$ with basis $\{\alpha_i, \beta_j\}$ for $i, j \in \{1, 2, 3\}$ and bi-invariant pairing $(\alpha_i, \beta_j) = \delta_{ij}$. The generating fields are defined as

\[ \alpha_i(z) = \sum_{n \in \mathbb{Z}} \alpha^i_n z^{-n-1}, \quad \beta_i(z) = \sum_{n \in \mathbb{Z}} \beta^i_n z^{-n-1}, \]

where we consider the basis $\alpha^i_n = \alpha_i \otimes t^n$ and $\beta^i_n = \beta_i \otimes t^n$ for $i = 1, 2, 3$ and $n \in \mathbb{Z}$.

Now, let us consider first a more basic example the torus.

### 1.1 Torus case

In this case we are considering a six dimensional torus, in our notation $\mathbb{T}^6 = M(0, 0)$. Now $\mathbb{T}^6 = \mathfrak{H}/\Lambda$ where $\mathfrak{H}$ is $\mathbb{R}^6$ endowed with the abelian group structure of the sum, $\Lambda$ is a discrete subgroup. We consider the abelian Lie algebra $\text{Lie}(\mathfrak{H}) = \mathfrak{h}$ and we construct out of this the Heisenberg vertex algebra $V^1(\mathfrak{h})$, we express the algebraic relations between its generating fields (2) as follows

\[ [\alpha_i(z), \beta_j(w)] = \delta_{ij} \partial_w \delta(z - w) \quad i, j \in \{1, 2, 3\}. \]

Considering the action of the Lie algebra $\mathfrak{h}$ on the function space of the torus $\mathbb{T}^6$, we define the space

\[ \mathcal{H} = \text{Ind}_{\mathfrak{h}[t]}^{\hat{\mathfrak{h}}} \mathbb{C} \mathbb{T}^2(\mathbb{T}^6). \]

By definition $\mathcal{H}$ is a module for the vertex algebra $V^1(\mathfrak{h})$. In some cases $\mathcal{H}$ has the structure of vertex algebra the lattice vertex algebra. We are motivated from the physical interpretation, to consider fields $\{x_i(z), y_j(z)\}$ associated to coordinates $\{x_i, y_i\}$ on the torus $\mathbb{T}^6$ such that these fields satisfy the relation

\[ \partial_z x_i(z) = \alpha_i(z), \quad \partial_z y_i(z) = \beta_i(z). \]

\(^3\)We used the notation in [2], where the loop algebra is defined as $L\mathfrak{h} := \mathfrak{h} \otimes \mathbb{C}(t)$ and the algebra $\hat{\mathfrak{h}} := L\mathfrak{h} \otimes \mathbb{K} \mathbb{C}$ as the central extension for the bi-invariant pairing.
Then we consider the logarithmic fields in \( \text{End}(\mathcal{H})[[z, z^{-1}]] \log z \)

\[
x_i(z) = w_i \log z + \sum_{n \in \mathbb{Z}} x_n^i z^{-n}, \quad y_i(z) = p_i \log z + \sum_{n \in \mathbb{Z}} y_n^i z^{-n},
\]

these fields satisfy the algebraic relation

\[
[x_i(z), y_j(w)] = \delta_{ij} \log(z - w) \implies [\partial_z x_i(z), \partial_w y_j(w)] = [\alpha_i(z), \beta_j(w)] = \delta_{ij} \partial_w \delta(z - w).
\]

Where the singularity is defined by

\[
\log(z - w) := i_{z,w} \log(z - w) - i_{w,z} \log(w - z) = \log z + \log \left(1 - \frac{w}{z}\right) - \log w - \log \left(1 - \frac{z}{w}\right)
\]

the notations \( i_{z,w} \) and \( i_{w,z} \) denote the expansion for \( z > w \) and \( w > z \) respectively. This is known as a logarithmic singularity. In this case is easy to see from (5) that the modes \( \{w_i, p_i, x_n^i, y_n^i\}_{n \in \mathbb{Z}} \) for \( i \in \{1, 2, 3\} \) satisfy a Lie algebra.

### 1.2 Twisted torus case

In this case, we consider the six dimensional nilmanifold\(^4\) \( M(0, 1) \), this nilmanifold is called the twisted torus. Now \( M(0, 1) = \mathcal{H}/\Lambda \) where \( \mathcal{H} \) is \( \mathbb{R}^6 \) endowed with a two step nilpotent structure, and \( \Lambda \) is a discrete subgroup. The nilpotent Lie algebra \( \text{Lie}(\mathcal{H}) = \mathfrak{h}_{0,1} \) is given by

\[
[\beta_i, \beta_j] = \epsilon_{ijk} \alpha_k, \quad [\alpha_i, \beta_j] = 0, \quad [\alpha_i, \alpha_j] = 0 \quad i, j \in \{1, 2, 3\}.
\]

Where \( \epsilon_{ijk} \) is the antisymmetric tensor. And we associate to this Lie algebra an affine Kac Moody vertex algebra \( V^1(\mathfrak{h}_{0,1}) \), we express the algebraic relations between its generating fields (2) as follows

\[
[\beta_i(z), \beta_j(w)] = \epsilon_{ijk} \delta(z - w) \quad [\alpha_i(z), \beta_j(w)] = \delta_{ij} \partial_w \delta(z - w) \quad i, j \in \{1, 2, 3\}.
\]

The nilpotent algebra \( \mathfrak{h}_{0,1} \) acts on the nilmanifold \( M(0, 1) \) and analogously we define a module for our vertex algebra

\[
\mathcal{H}_{0,1} = \text{Ind}^\mathcal{H}_{\mathfrak{h}_{0,1}[[t]] \oplus \mathbb{C} \mathbb{K}} L^2(M(0, 1)) \simeq U(\mathfrak{h}) \otimes U(\mathfrak{h}_{0,1}[[t]] \oplus \mathbb{C} \mathbb{K}) L^2(M(0, 1)).
\]

We are motivated from the physical interpretation to consider the following way to build the fields \( \{x_i(z), y_i(z)\} \). The nilmanifold \( M(0, 1) \) comes with a global framing on its cotangent bundle given by \( T^* M(0, 1) \approx \mathfrak{h}_{0,1} \), then we express with coordinates \( \{x_i, y_i\} \) on \( M(0, 1) \) a basis \( \{\alpha_i, \beta_j\} \) of \( \mathfrak{h}_{0,1}^* \).

\[
\alpha_i = dx_i, \quad \beta_i = dy_i - \frac{1}{2} \epsilon_{ijk} x_j dx_k.
\]

Then, also, these are the relations between their fields

\[
\partial_z x_i(z) = \alpha_i(z), \quad \partial_z y_i(z) = \beta_i(z) + \frac{1}{2} \epsilon_{ijk} x_j(z) \partial_z x_k(z).
\]

\(^4\)The case \( M(1, 0) \) is similar to the twisted torus case, the reason behind this is the T-duality.
We can find the logarithmic fields $\text{End}(\mathcal{H}_{0,1})[[z, z^{-1}]](\log z)$ associated to the coordinates integrating the relations before\(^5\),

\[
x_i(z) = w_i \log z + \sum_{n \in \mathbb{Z}} x_n^i z^{-n}, \quad y_i(z) = p_i \log z + \sum_{n \in \mathbb{Z}} y_n^i z^{-n} + \frac{\varepsilon_{ijk}}{2} w_j x_k(z) \log z.
\]

The algebraic relations between these fields are restricted by their relations with the fields $\{\alpha_i(z), \beta_j(z)\}$ in (8) and (7) in the same way that happens in the torus case (5). We emphasize here that the logarithmic singularity (6) is no enough to express the algebraic relations for these fields, for example the relation between the fields $y_i(z)$ and $y_j(w)$ satisfy a relation that has the following form

\[
[y_i(z), y_j(w)] = (...)\log(z - w) + \frac{1}{2} \varepsilon_{ijk} w_k r(l, z, w).
\]

Here the notation (...) means some expressions that involve fields, we express the complete relations in (22). In this case the Roger’s dilogarithm $r(l) := Li_2(x) + \frac{1}{2} \log x \log(1 - x)$ appears naturally as a singularity

\[
rl(z, w) = Li_2\left(\frac{z}{w}\right) + \frac{1}{2} \log\left(\frac{z}{w}\right) \log(1 - \frac{z}{w}) + Li_2\left(\frac{w}{z}\right) + \frac{1}{2} \log\left(\frac{w}{z}\right) \log(1 - \frac{w}{z})
\]

\[
= Li_2\left(\frac{z}{w}\right) + Li_2\left(\frac{w}{z}\right) + \frac{1}{2} (\log w - \log z)^2 - \frac{1}{2} (\log z - \log w) \log(z - w).
\]

In this case also the modes $\{w_i, p_i, x_n^i, y_n^i\}_{n \in \mathbb{Z}}$ for $i \in \{1, 2, 3\}$ form a Lie algebra, we can see this Lie algebra as a particular case of the algebra that we found in the following case.

The twisted torus case was studied in [1] with the Hamiltonian formalism, and from a perturbative CFT point of view in [2]. In these works, the authors also work around the interpretation of this singularity and its identities to explain properties in vertex algebras and CFT. We show in the appendix the relation between these two formalism working their physical interpretations, on the one hand we have the Hamiltonian point of view of and on the other hand we have an CFT perturbative point of view.

1.3 Twisted nilmanifolds case

In this work we consider the more general case given by the six dimensional nilmanifolds $M(k, j)$. The natural appearance of the Roger’s dilogarithm on the previous case motivated us to study the singularities of these logarithmic fields in more general cases. Also in this case we do not have an perturbative CFT interpretation therefore we have only the Hamiltonian formalism in this case.

we consider the six dimensional nilmanifold $M(k, j)$, we called this case the twisted nilmanifold case. Now $M(k, j) = \mathfrak{f} / \Lambda$ where $\mathfrak{f}$ is $\mathbb{R}^6$ endowed with a three step nilpotent structure, and $\Lambda$ is a discrete subgroup. The nilpotent Lie algebra $\text{Lie}(\mathfrak{f}) = \mathfrak{h}_{k,j}$ is given by

\[
[\beta_1, \beta_2] = j \alpha_3, \quad [\beta_3, \beta_1] = j \alpha_2 + k \beta_2, \quad [\beta_2, \beta_3] = j \alpha_1,
\]

\[
[\beta_1, \alpha_2] = k \alpha_3, \quad [\beta_2, \alpha_2] = 0, \quad [\alpha_2, \beta_3] = k \alpha_1.
\]

\(^5\)These fields have an interpretation related with the loop space $LM(0,1)$ following the Hamiltonian interpretation.
We associate to this Lie algebra an affine Kac Moody vertex algebra $\mathcal{V}^1(\mathfrak{h}_{0,1})$, we express the algebraic relations between its generating fields (2) as follows

\[
[\beta_1(z), \beta_2(w)] = j\alpha_3(w)\delta(z - w), \quad [\beta_2(z), \beta_3(w)] = j\alpha_1(w)\delta(z - w), \\
[\beta_1(z), \alpha_2(w)] = k\alpha_3(w)\delta(z - w), \quad [\alpha_2(z), \beta_3(w)] = k\alpha_1(w)\delta(z - w), \\
[\beta_3(z), \beta_1(w)] = (j\alpha_2(w) + k\beta_2(w))\delta(z - w), \quad [\alpha_1(z), \beta_4(w)] = \partial_w\delta(z - w).
\]

The nilpotent algebra $\mathfrak{h}_{k,j}$ acts on the nilmanifold $M(k,j)$ and analogously we define a module for our vertex algebra

\[
\mathcal{H}_{k,j} = \text{Ind}^\mathcal{H}_{\mathfrak{h}_{k,j}[[t]]} \mathcal{C} \mathcal{K} \mathcal{L}^2(M(k,j)) \simeq U(\mathcal{H}) \otimes U(\mathfrak{h}_{k,j}[[t]]) \mathcal{C} \mathcal{K} \mathcal{L}^2(M(k,j)).
\]

Following the same idea in (8) we express the fields $\{x_i(z), y_j(z)\}$ in (26). We find a new singularity for the fields $\{x_i(z), y_j(z)\}$ which satisfy the restriction in (25) and the algebra of the fields $\{\alpha_i(z), \beta_j(z)\}$ in (11). For example the relation between the fields $y_1(z)$ and $y_3(w)$ satisfy a relation that has the following form

\[
[y_1(z), y_3(w)] = (...) \log(z - w) + (...)r l(z, w) - kjw_3 w t(z, w)
\]

Here the notation $(...)\delta_{ij}$ means some expressions that involve fields. We express the complete relations in the theorem 4.1. In this case the new singularity is given by

\[
t(z, w) = -2 \left( L_3(\frac{z}{w}) - L_3(\frac{w}{z}) \right) + (\log z - \log w) \left( L_2(\frac{z}{w}) + L_2(\frac{w}{z}) \right) \\
+ \frac{1}{6}(\log z - \log w)^3 - \frac{1}{6}(\log z^2 - 3\log w\log z + \log w^2)\log(z - w).
\]

In this case the modes $\{w_i, p_i, x_i^j, y_i^j\}_{i \in \mathbb{Z}}$ for $i \in \{1, 2, 3\}$ form a non-linear Lie algebra, we give the definition of non-linear Lie algebras in the section 3.3 and we express the non-linear Lie algebra that we found in the theorem (4.2).

This work is organized as follows. In section 2, we give short physics motivation. In section 3, we introduce and define the objects that we use. In section 4, we express the fields and the algebra that we have from studying the general case $k \neq 0$ and $j \neq 0$.

**Acknowledgment:** I thank Reimundo Heluani for his continuous support while this work was done, also I want to thank thank Jethro Van Ekeren, Pedram Hekmathi and Alejandro Cabrera for inspiring conversations. This work was done at IMPA, and was finally completed at Virginia Commonwealth University with the help of Marco Aldi. I would like to thank these institutions for hospitality and excellent working conditions.

## 2 Physics motivation

In this section we give a very short motivation to some constructions done in this work. A more complete treatment of the concepts introduced here can be consulted in the cited references.
2.1 The current algebras

It is well known in physics that in the CFT formalism on the torus there is a symmetry called T-duality, for a vertex algebraic approach see [3]. On the other hand, an analogous study of symmetries as T-duality becomes more complicated in general cases. In particular, we are interested in cases where instead of the torus we have nilmanifolds. There is an interesting relation at the topological level of T-duality between three dimensional Heisenberg nilmanifolds $N(k)$ with $H_3$-flux, [6]. The nilmanifolds $N(k)$ is a $S^1$-bundle

$$S^1 \rightarrow N(k) \rightarrow \mathbb{T}^2,$$

where $k \in \mathbb{Z} \simeq H^2(\mathbb{T}^2, \mathbb{Z})$ is the Chern class. And the $H$-flux is given by a three form $H_j$ s.t $[H_j] = j \in \mathbb{Z} \simeq H^3(N(k), \mathbb{Z})$. For these nilmanifolds we can try to develop a theory similar to the case of the torus. However, several problems arise. In particular, only on the torus we have a CFT. Therefore, we consider a different approach, the Hamiltonian formalism.

From this point of view we have a relation between Poisson brackets of certain fields called currents and Courant brackets [4]. We now describe this relationship in vertex algebras for the nilmanifolds. We will restrict ourselves to consider only global sections of $TN(k) \oplus T^*N(k)$ given by

$$\beta_1 = \partial_x + \frac{k}{2} \partial_y, \quad \beta_2 = \partial_y, \quad \beta_3 = \partial_z - \frac{k}{2} x \partial_y,$$

$$\alpha_1 = dx, \quad \alpha_2 = dy + \frac{k}{2} x dz - \frac{k}{2} z dx, \quad \alpha_3 = dz.$$

The Courant brackets between these sections are given by the Lie algebra (10). We denoted this Lie algebra as $\mathfrak{h}_{k,j}$, this Lie algebra comes with the bi-invariant pairing given by $(\alpha_i, \beta_j) = \delta_{ij}$. The current algebra in [4] can be described in the vertex algebra formalisms as the Kac Moody vertex algebra $V^1(\mathfrak{h}_{k,j})$ where

$$V^1(\mathfrak{h}_{k,j}) = Ind_{\mathfrak{h}_{k,j}}[\mathfrak{h}] \oplus \mathbb{C} K \langle 0 \rangle = U(\mathfrak{h}_{k,j}) \otimes (U(\mathfrak{h}_{k,j}) \otimes \mathbb{C}K) \subset \mathbb{C}$$

where $K$ acts as $K = 1 Id$. The generating fields satisfy the algebra given in (11). In

2.2 The double

The doubles spaces are important in physics, especially in double field theory [15].

In the Hamiltonian formalism on the torus $T^*\mathbb{T}^3$, case $k = j = 0$, we have fields $x_i(z)$ and $p_i(z)$ which are related to the current algebra by $\partial_z x_i(z) = \alpha_i(z)$ and $p_i(z) = \beta_i(z)$. For these fields, T-duality leads to consider transformations where $p_i(z)$ and $\partial_z x_i(z)$ will change their roles, therefore one ends up considering fields $y_i(z)$ such that $\partial_z y_i(z) = p_i(z)$. Now, we could instead of $T^*\mathbb{T}^3$ consider the double $\mathbb{T}^6$, a space where both fields are considered $(x_i(z), y_i(z))$ at the same time. This space realized the T-duality and other properties naturally. In

---

6The relation between between Courant brackets and T-duality, for example in [7], can be associated to the Poisson brackets in [4], this approach was considered in [8].

7Here the variable $z$ is the standard notation in the vertex algebra language but it is not related to the light cone coordinates in physics. The notation in physics for Poisson brackets uses the variable $\sigma$ that we interpreted as $z = e^{\sigma}$.

8The fields $y_i(z)$ have also an interpretation in CFT, for example the zero mode of the field $y_i(z)$ gives us the operator that jumps between the windings lattice.
particular, the double for nilmanifolds $N(k)$ with $H_j$ flux was studied from this point of view in [5]. Mathematically, we can describe these doubles as torus fibrations

$$\mathbb{T}^3 \rightarrow M(k,j) \rightarrow S^1 \rightarrow N(k) \rightarrow \mathbb{T}^2$$

for $k \in H^2(\mathbb{T}^2, \mathbb{Z}) \cong \mathbb{Z}$ and $j \in H^3(N(k), \mathbb{Z}) \cong \mathbb{Z}$.

The fields $x_i(z)$ and $y_i(z)$ on the double $M(k,j)$ are given by logarithmic fields as we explain in the section 3. Algebraically, $x_i(z)$ and $y_i(z)$ are fields in $\text{End}(\mathcal{H}(k,j))[z, z^{-1}][\log z]$.

In this work we are interested in the singularities between these logarithmic fields have, these singularities are restricted by the relation to the affine Kac Moody vertex algebra $V^1(h_{k,j})$.

3 The double and the logarithmic fields for nilmanifolds

In this section we introduce some definition and objects, we assume knowledge of vertex algebras. For a introduction to vertex algebras see [10], [11] and [12].

3.1 The courant bracket and the double for nilmanifolds

For any smooth manifold $N$ its space of vector fields, or sections of its tangent bundle $TN$ forms a Lie algebra under the Lie bracket of vector fields. In [13], it was shown how to extend this algebraic structure to a bilinear bracket on $TN \oplus T^*N$ which does not quite satisfy the Lie algebra axioms. The Dorfman bracket and more generally the twisted Dorfman bracket for a choice of $H \in \Gamma(\wedge^3 T^*N)$, a closed three form, is defined as

$$[X + \xi, Y + \eta]_H = [X, Y]_{\text{Lie}} + L_X \eta - i_Y d\xi + i_Y i_X H, \quad X + \xi, Y + \eta \in \Gamma(TN \oplus T^*N).$$

Whenever there exist global orthonormal framings for the symmetric pairing

$$(X + \xi, Y + \eta) = \eta(X) + \xi(Y),$$

in $(TN \oplus T^*N) \otimes \mathbb{C}$ and linearly closed under the bracket (13), we obtain a global trivialization $(TN \oplus T^*N) \cong \mathfrak{h} \times N$ and the bracket (13) endows $\mathfrak{h}$ with a Lie algebra structure.

We consider compact nilmanifolds $N = G/\Gamma$ expressed as a quotient of the nilpotent Lie group $G$ by a co-compact lattice $\Gamma \subset G$. We choose a three form $H$, called $H$-flux in physics literature, representing a class in $H^3(N, \mathbb{Z})$. In this situation the tangent bundle of $N$ is naturally trivialized as $g \times N$, where $g = \text{Lie}(G)$. There exist global framings, a basis of $\mathfrak{h}$, with the above properties and the Lie algebra $\mathfrak{h}$ fits into a short exact sequence

$$0 \rightarrow g^* \rightarrow \mathfrak{h} \rightarrow g \rightarrow 0,$$

the class of this extension is parametrized by $H$ viewed as a map $\wedge^2 g \rightarrow g^*$. The exact sequence (15) integrates, for $H \in H^3(N, \mathbb{Z})$, to Lie groups and co-compact discrete subgroups as

$$0 \rightarrow G^* \rightarrow \mathfrak{g} \rightarrow G \rightarrow 0, \quad 0 \rightarrow \Gamma^* \rightarrow \Lambda \rightarrow \Gamma \rightarrow 0, \quad \Gamma^* \subset G^*, \quad \Lambda \subset \mathfrak{g}, \quad \Gamma \subset G.$$
Then we define the double \( M \) as a torus bundle
\[
\mathbb{T}^{\dim N} = G^*/\Gamma^* \to M := S\gamma/\Lambda
\]
\[N = G/\Gamma.\]

### 3.2 Logarithmic fields

If we consider the current algebra in \([4]\) for a nilmanfold \( N = G/\Gamma \), and we restricted ourselves to the global sections of \((T N \oplus T^* N) \cong \frak{h} \times N\) then the current algebra is given by an affine Kac Moody vertex algebra
\[
V^1(\frak{h}) = \text{Ind}^{\hat{\frak{h}}}_{\frak{h}[t] \otimes \mathbb{C}K} |0\rangle,
\]
(17)
where \( \frak{h} \) is the Lie algebra \((13)\) and the bi-invariant pairing is given by \((14)\).

We are interested in considering more general fields than the fields of the vertex algebra \( V^1(\frak{h}) \). In order to introduce these fields we must work in larger space of states than \((17)\). In particular, we consider
\[
\mathcal{H} = \text{Ind}^{\hat{\frak{h}}}_{\frak{h}[t] \otimes \mathbb{C}K} L^2(M) \cong U(\hat{\frak{h}}) \otimes U(\frak{b}[t] \otimes \mathbb{C}K) L^2(M).
\]
(18)

Where we consider the induced action from the Lie group \( S\gamma \) (and therefore its Lie algebra \( \frak{h} \)) on \( L^2(M) \) by right translations, hence it arises the infinite dimensional \( \hat{\frak{h}} \)-module. We notice that \( L^2(M) \) is a completion of the group algebra \( \mathbb{C}[\Lambda]\) by Fourier expansion.

In this work we associate coordinates to logarithmic fields as follows. First, the nilmanifold \( M \) comes with a global framing on its cotangent bundle given by \( T^* M \cong \frak{h}^* \times M \), then we express with coordinates \((x_i)\) on \( M \) a basis \((\alpha_i)\) of \( \frak{h}^* \) and we assume that these are relations that satisfy their fields.
\[
\alpha_i = f(x_i) dx_i \quad \Rightarrow \quad \alpha_i(z) = f(x_i(z)) \partial_z x_i(z).
\]
(19)
The motivation behind this comes from the Hamiltonian formalism, the current algebra for \( N \) relates \((u_i, \alpha_i) \in T N \oplus T^* N\) with fields \((u_i(z)p_i(z), \alpha_i(z) \partial_z x_i(z))\). The elements that accompany \( \partial_z x_i(z) \) come from sections on the cotangent bundle on \( N \). On the double \( M \) this corresponds to \((19)\).

Second, we express the fields \( x_i(z) \) in modes such that they satisfy \((19)\). Therefore we must consider fields which are also expanded by \( \log(z) \) and their modes will be expressed by operators on \( \mathcal{H} \). Then we will have fields on
\[
\text{End}(\mathcal{H})[[z, z^{-1}]]\log z\]
(20)
Finally, the algebraic relations for \( x_i(z) \) are not necessarily expressed by singularities given by delta functions and their derivatives because we are working with logarithmic fields. In general, we do not know in advance what kind of singularities we could have between the \( x_i(z) \) fields. In this work we study the singularities that we could have for a particular class of nilmanifolds. Note that the singularities for the logarithmic fields are restricted by \((19)\) given that this impose relations with the affine Kac Moody algebra \( V^1(\frak{h})\).
Example 3.1 (The torus case, $k = j = 0$). In this case $\mathfrak{h}$ is abelian, then $M = \mathbb{T}^6$ and (19) gives us the simple relations

$$\alpha_i = dx_i, \quad \beta_i = dy_i \quad \Rightarrow \quad \partial_z x_i(z) = \alpha_i(z), \quad \partial_z y_i = \beta_i(z). \tag{21}$$

The more general fields which satisfies the relation above can be expressed by the logarithmic fields

$$x_i(z) = w_i \log z + \sum_{n \in \mathbb{Z}} x_n^i z^{-n}, \quad y_i(z) = p_i \log z + \sum_{n \in \mathbb{Z}} y_n^i z^{-n}.$$

These fields satisfy the logarithmic singularity

$$[x_i(z), y_j(w)] = \log(z - w),$$

we defined this singularity in (6).

Example 3.2 (The double twisted torus case $k = 0$, $j = 1$). In this case $\mathfrak{h}$ is not abelian but 2 step nilpotent, and $M$ is a $\mathbb{T}^3$-fibration over $\mathbb{T}^3$, (19) gives us the relations

$$\alpha_i = dx_i, \quad \beta_i = dy_i - \frac{1}{2} \varepsilon_{ijk} x_k dx_k \quad \Rightarrow \quad \partial_z x_i(z) = \alpha_i(z), \quad \partial_z y_i(z) = \beta_i(z) + \frac{1}{2} \varepsilon_{ijk} : x_j(z) \partial_z x_k(z):.$$

The more general fields which satisfies the relation above can be expressed by the logarithmic fields

$$x_i(z) = w_i \log z + \sum_{n \in \mathbb{Z}} x_n^i z^{-n}, \quad y_i(z) = p_i \log z + \sum_{n \in \mathbb{Z}} y_n^i z^{-n} + \frac{1}{2} \varepsilon_{ijk} w_j x_k(z) \log z.$$

These fields satisfy the following algebraic relations

$$[x_i(z), x_j(w)] = 0, \quad [x_i(z), y_j(w)] = \delta_{ij} \log(z - w),$$

$$[y_i(z), y_j(w)] = \varepsilon_{ijk} w_k \log(z, w) + \frac{1}{2} \varepsilon_{ijk} (\hat{x}_k(z) - \hat{x}_k(w)) \log(z - w). \tag{22}$$

Where we used the singularity (9) and the notation $\hat{x}_i(z)$ means the projection onto fields without log $z$ terms, that is $\hat{\cdot} : \text{End}(\mathcal{H})[[z, z^{-1}]] \log z \to \text{End}(\mathcal{H})[[z, z^{-1}]]$.

For the general case $k \neq 0$ and $j \neq 0$, we will express the algebraic relation between the modes $\{w_i, p_i, x_n^i, y_n^i\}$ for $n \in \mathbb{Z}$ and $i \in \{1, 2, 3\}$. For the particular examples before the algebra of these modes is a Lie algebra, but for the general case the modes will form a nonlinear Lie algebra.

### 3.3 Non-linear Lie algebras

In this section we follow [14]. Let $\mathfrak{g}$ a vector space, and let $T(\mathfrak{g})$ denote the tensor algebra over $\mathfrak{g}$. If $\mathfrak{g}$ is endowed with a linear map

$$[,] : \mathfrak{g} \otimes \mathfrak{g} \to T(\mathfrak{g}).$$

We extended it to $T(\mathfrak{g})$ by the Leibnitz rule, for $A, B \in T(\mathfrak{g})$

$$[A \otimes B, C] = [A, C] \otimes B + A \otimes [B, C], \quad [A, B \otimes C] = [A, B] \otimes C + B \otimes [A, C].$$
We define
\[ \mathcal{M}(\mathfrak{g}) := \text{span}\{ A \otimes (b \otimes c - c \otimes b - [b, c]) \otimes D | b, c \in \mathfrak{g}, A, D \in T(\mathfrak{g}) \}. \]

Note that \( \mathcal{M}(\mathfrak{g}) \) is the two sided ideal of the tensor product \( T(\mathfrak{g}) \) generated by elements \( (b \otimes c - c \otimes b - [b, c]) \), where \( a, b \in \mathfrak{g} \).

**Definition 3.1.** A non-linear Lie algebra \( \mathfrak{g} \) is a vector space with a linear map \([,] : \mathfrak{g} \otimes \mathfrak{g} \to T(\mathfrak{g})\) satisfying the following properties (\( a, b, c \in \mathfrak{g} \))

- skewsymmetry: \([a, b] = -[b, a] \).
- \([a, [b, c]] - [b, [a, c]] - [[a, b], c] \in \mathcal{M}(\mathfrak{g}) \).

The associative algebra \( U(\mathfrak{g}) = T(\mathfrak{g})/\mathcal{M}(\mathfrak{g}) \) is called the universal enveloping algebra of the non-linear Lie algebra \( \mathfrak{g} \).

## 4 Logarithmic fields and their singularities, case \( k \neq 0 \) and \( j \neq 0 \)

In this section we describe the double \( M(k, j) \), their logarithmic fields. We express the singularities of these fields, and also we give the expression of the algebra.

### 4.1 The double \( M(k, j) \) and their logarithmic fields \( x_i(z) \) and \( y_i(z) \)

Let \( k \in \mathbb{Z} \) and \( G_k \) be the 3-dimensional Heisenberg group. It is the manifold \( G_k = \mathbb{R}^3 \) with multiplication:

\[
(x, y, z)(x', y', z') = \left( x + x', y + y' - \frac{k}{2}xz' + \frac{k}{2}x'z, z + z' \right).
\]

Let \( \Gamma \subset G_k \) be the subgroup generated by the standard basis of \( \mathbb{R}^3 \). It is a co-compact lattice. We have the corresponding nilmanifold, usually referred to as the *Heisenberg nilmanifold* \( N(k) := G_k/\Gamma \). Notice that for all \( k \) the groups \( G_k \) are isomorphic, but under these isomorphisms, the corresponding \( \Gamma \) are not intertwined.

Let \( j \in \mathbb{Z} \simeq H^3(N, \mathbb{Z}) \) and consider a three form \( H_j = -jdz \wedge dy \wedge dz \) representing this class. In particular, sections of the bundle \( TN(k) \oplus T^*N(k) \) are endowed with a bilinear operation (the \( H \)-twisted Dorfman bracket (13)). This bundle admits a global framing with their respective brackets given in (10). Hence we obtain the 6 dimensional three step nilpotent Lie algebra \( \mathfrak{h}_{k,j} \) and the trivialization \( TN(k) \oplus T^*N(k) \simeq \mathfrak{h}_{k,j} \times N \). Notice that \( \mathfrak{h}_{k,j} \) fits into a short exact sequence as in (15), and this extension is an abelian extension but it is not a central extension if \( k \neq 0 \).

Let \( \mathcal{N}_{k,j} \) be the nilpotent Lie group with Lie algebra \( \mathfrak{h}_{k,j} \). As a manifold it is \( \mathbb{R}^6 \), its
multiplication table can be found by the BCH formula:

\[
(x_1, x_2, x_3, y_1, y_2, y_3)(x_1^*, x_2^*, x_3^*, y_1^*, y_2^*, y_3^*) = (x_1^{**}, x_2^{**}, x_3^{**}, y_1^{**}, y_2^{**}, y_3^{**})
\]

\[
x_1^{**} = x_1 + x_1^*, \quad x_3^{**} = x_3 + x_3^*, \quad x_2^{**} = x_2 + x_2^* + \frac{k}{2}(x_3x_1^* - x_1x_3^*)
\]

\[
y_1^{**} = y_1 + y_1^* + \frac{k}{2}(y_2x_3^* - y_2^*x_3) + \frac{j}{2}(x_2x_3^* - x_2^*x_3) + \frac{k}{6}(x_3^* - x_3)(x_3x_1^* - x_1x_3^*)
\]

\[
y_2^{**} = y_2 + y_2^* + \frac{j}{2}(x_3x_1^* - x_1x_3^*)
\]

\[
y_3^{**} = y_3 + y_3^* + \frac{k}{2}(x_1y_2^* - x_1^*y_2) + \frac{j}{2}(x_1x_2^* - x_1^*x_2) + \frac{k}{6}(x_1 - x_1^*)(x_3x_1^* - x_1x_3^*)
\]

Remark 1. It turns out that \(M(k, j) = M(j, k)\), a phenomenon which can be explained by topological T-duality. \cite{[15]} gives a physics interpretation of the double. A similar construction is given in \cite{[6]} where instead of \(M(k, j)\) consider, \(N(k) \times T^3 N(j)\). Also, we consider nilmanifolds and work in particular with global sections therefore many properties that we studied comes from the nilpotent Lie algebras, then we have similar properties with Poisson-Lie T-duality \cite{[9]}.

\(M(k, j)\) is a nilmanifold therefore its cotangent bundle can be trivialized with left invariant forms given by:

\[
\alpha_1 = dx_1, \quad \alpha_2 = dx_2 - \frac{1}{2}kx_3dx_1 + \frac{1}{2}kx_1dx_3, \quad \alpha_3 = dx_3,
\]

\[
\beta_1 = dy_1 - \frac{kj}{3}x_3^2dx_1 + \frac{1}{2}jx_3dx_2 - \frac{1}{2}(ky_2 + jx_2)dx_3 + \frac{kj}{3}x_1x_3dx_3 + \frac{1}{2}kx_3dy_2,
\]

\[
\beta_2 = dy_2 - \frac{1}{2}jx_3dx_1 + \frac{j}{2}x_1dx_3,
\]

\[
\beta_3 = dy_3 + \frac{kj}{3}x_3x_1dx_1 + \frac{1}{2}(ky_2 + jx_2)dx_1 - \frac{1}{2}jx_1dx_2 - \frac{kj}{3}x_1^2dx_3 - \frac{1}{2}kx_1dy_2.
\]

And (19) gives us the relations

\[
\alpha_1(z) = \partial x_1(z), \quad \alpha_2(z) = \partial x_2(z) - \frac{1}{2}kx_3(z)\partial x_1(z) + \frac{1}{2}kx_1(z)\partial x_3(z), \quad \alpha_3(z) = \partial x_3(z),
\]

\[
\beta_1(z) = \partial y_1(z) + \frac{1}{2}j(x_3(z)\partial x_2(z) - x_2(z)\partial x_3(z)) + \frac{1}{2}k(x_3(z)\partial y_2(z) - y_2(z)\partial x_3(z)) - \frac{kj}{3}x_3^2(z)\partial x_1(z) + \frac{kj}{3}x_3(z)x_1(z)\partial x_3(z),
\]

\[
\beta_2(z) = \partial y_2(z) - \frac{1}{2}jx_3(z)\partial x_1(z) + \frac{j}{2}x_1(z)\partial x_3(z),
\]

\[
\beta_3(z) = \partial y_3(z) + \frac{1}{2}j(x_2(z)\partial x_1(z) - x_1(z)\partial x_2(z) + \frac{1}{2}k(y_2(z)\partial x_1(z) - x_1(z)\partial y_2(z)) - \frac{kj}{3}x_3^2(z)\partial x_3(z) + \frac{kj}{3}x_3(z)x_1(z)\partial x_1(z).
\]
The more general fields which satisfies the relation above can be expressed by the follow logarithmic fields

\[
x_1(z) = w_1 \log z + \sum x_n^1 z^{-n},
\]

\[
x_3(z) = w_3 \log z + \sum x_n^3 z^{-n},
\]

\[
x_2(z) = w_2 \log z + \sum x_n^2 z^{-n} + \frac{1}{2} j k_2 \log (w_3 x_1 (z) - w_1 x_3 (z)),
\]

\[
y_2(z) = p_2 \log z + \sum y_n^2 z^{-n} + \frac{1}{2} j k_2 \log (w_3 x_1 (z) - w_1 x_3 (z)),
\]

\[
y_1(z) = p_1 \log z + \sum y_n^1 z^{-n} + 1/2 k_1 \log (p_2 x_3 (z) - w_3 y_2 (z)) + j/2 \log (w_2 x_3 (z) - w_3 x_2 (z)) + \frac{k j}{6} x_3 (z) \log (w_3 x_1 (z) - w_1 x_3 (z)),
\]

\[
y_3(z) = p_3 \log z + \sum y_n^3 z^{-n} + 1/2 k_1 \log (w_1 y_2 (z) - p_2 x_1 (z)) + j/2 \log (w_1 x_2 (z) - w_2 x_1 (z)) - \frac{k j}{6} x_1 (z) \log (w_3 x_1 (z) - w_1 x_3 (z)).
\]

(26)

### 4.2 Algebraic relations between the logarithmic fields \(x_i(z)\) and \(y_i(z)\)

For arbitrary \(k\) and \(j\) the algebraic relations are substantially more complicated than the previous cases in the examples 3.1 and 3.2.

**Theorem 4.1.** For the fields \(x_i(z)\) and \(y_i(z)\) in (26) the next commutation relations imply that the fields \(\alpha_i(z)\) and \(\beta_i(z)\) in (25) satisfies the commutation relations in (11) for the affine Kac Moody vertex algebra \(V^1(\mathfrak{h}_{k,j})\).

\[
[x_1(z), y_j(w)] = \delta_{ij} \log (z - w),
\]

\[
y_1(z), y_2(w)] = \frac{j}{2} (x^3(z) - \hat{x}^3(w)) \log (z - w) + j w_3 r l (w, z),
\]

\[
y_1(z), x_2(w)] = \frac{k}{2} (x^3(z) - \hat{x}^3(w)) \log (z - w) + k w_3 r l (w, z),
\]

\[
y_2(z), y_3(w)] = \frac{j}{2} (x^1(z) - \hat{x}^1(w)) \log (z - w) + j w_1 r l (w, z),
\]

\[
x_2(z), y_3(w)] = \frac{k}{2} (x^1(z) - \hat{x}^1(w)) \log (z - w) + k w_1 r l (w, z),
\]

\[
y_1(z), y_1(w)] = -\frac{k j}{6} (x_3(z)^2 + \hat{x}_3(w)^2 - 3 x_3(z) \hat{x}_3(w)) \log (z - w)
\]

\[
+ \frac{k j}{6} w_3 (x_3(w) \log w + \hat{x}_3(z) \log z) log (z - w)
\]

\[
+ k j w_3 (x_3(w) - \hat{x}_3(z)) r l (z, w) + k j w_3 w_3 r l (z, w),
\]

\[
y_1(z), y_3(w)] = \frac{k}{2} (y_2(z) - \hat{y}_2(z)) \log (z - w) + \frac{j}{2} (\hat{x}_2(w) - \hat{x}_2(z)) \log (z - w)
\]

\[
+ \frac{k j}{6} (x_3(z) \hat{x}_1(z) + \hat{x}_1(w) \hat{x}_3(z) - 3 \hat{x}_3(z) \hat{x}_1(w)) \log (z - w)
\]

\[
+ \frac{k j}{6} (w_3 \hat{x}_1(w) \log w - 2 w_3 \hat{x}_1(z) \log z + w_1 \hat{x}_3(z) \log z - 2 w_1 \hat{x}_3(w) \log w) \log (z - w)
\]

\[
+ k j (w_1 \hat{x}_3(z) - w_3 \hat{x}_1(w)) r l (z, w) - (j w_2 + k p_2) r l (z, w) - k j w_3 w_1 t (z, w),
\]

12
\[ [y_3(z), y_3(w)] = -\frac{k_j}{6} (\hat{x}_1(z)^2 + \hat{x}_1(w)^2 - 3\hat{x}_1(z)\hat{x}_1(w)) \log(z - w) + \frac{k_j}{6} w_1 (\hat{x}_1(w)\log w + \hat{x}_1(z) \log z) \log(z - w) + k j w_1 (\hat{x}_1(w) - \hat{x}_1(z)) r_l(z, w) + k j w_1 w_1 t(z, w), \]

where the function \( t(z, w) \) is the function defined in (12).

The proof of this theorem is given in the appendix B.

The modes, when expressed as operators acting on \( \mathcal{H}(k, j) \) are not linearly closed under commutators. In fact, they form a non-linear Lie algebra, see section 3.3. The commutation relations between these modes, while not a linear combination of themselves, is compatible with the Jacobi identity.

**Theorem 4.2.** For each pair of integer numbers \( k, j \) there exists a non-linear Lie algebra with basis \( \{ x^i_n, y^i_m, w_i, p_j \}, i = 1, 2, 3, n \in \mathbb{Z} \), the quadratic commutation relations are given by

\[
[x^i_n, y^i_m] = \delta_{ij} \delta_{n, -m} m, \\
[y^i_n, y^i_m] = \frac{j}{2} x^{i + m}_n \left( \frac{1}{n} + \frac{1}{m} \right) + j w_3 \delta_{n, -m} m^{-2}, \\
[y^i_n, x^i_m] = \frac{k}{2} x^{i + n}_m \left( \frac{1}{n} + \frac{1}{m} \right) + k w_3 \delta_{n, -m} m^{-2}, \\
[y^i_n, y^i_m] = \frac{j}{2} x^{i + m}_n \left( \frac{1}{n} + \frac{1}{m} \right) + j w_3 \delta_{n, -m} m^{-2}, \\
[y^i_n, x^i_m] = \frac{k}{2} x^{i + n}_m \left( \frac{1}{n} + \frac{1}{m} \right) + k w_3 \delta_{n, -m} m^{-2}, \\
[y^i_n, y^i_m] = -2k j w_3 w_3 \delta_{n, -m} m^{-3} - kj \left( \frac{1}{m} - \frac{1}{n} \right) w_3 x^{i + m}_n + kj \frac{2}{l} \sum_{l} x^{i + l}_n x^{i + m - l}_n \left( \frac{1}{m} - \frac{1}{n} \right), \\
[y^i_n, y^i_m] = \frac{1}{2} \left( k y^2_{n + m} + j x^2_{n + m} \right) \left( \frac{1}{n} + \frac{1}{m} \right) - (kp_2 + jw_2) \delta_{n, -m} m^{-2} + 2k j w_1 w_3 \delta_{n, -m} m^{-3} + kj \left( \frac{1}{m} - \frac{1}{n} \right) w_1 x^{i + m}_n + kj \frac{2}{l} \sum_{l} x^{i + l}_n x^{i + m - l}_n \left( \frac{1}{m} - \frac{1}{n} \right), \\
[y^i_n, x^i_m] = -2k j w_1 w_3 \delta_{n, -m} m^{-3} - kj \left( \frac{1}{m} - \frac{1}{n} \right) w_1 x^{i + m}_n + kj \frac{2}{l} \sum_{l} x^{i + l}_n x^{i + m - l}_n \left( \frac{1}{m} - \frac{1}{n} \right), \\
[w_i, p_j] = \delta_{ij} \delta_{0, m}, \quad [x^i_n, p_j] = -\delta_{ij} \delta_{0, n}, \quad [w_i, p_j] = [p_1, p_1] = [p_3, p_3] = 0, \\
[p_1, y^3_m] = \frac{j}{2} x^3_m, \quad [y^3_n, p_2] = \frac{j}{2} x^3_n, \quad [p_1, x^2_m] = \frac{k}{2} x^2_m, \quad [y^1_n, w_2] = \frac{k}{2} x^3_n, \\
[p_2, y^3_m] = \frac{j}{2} x^3_m, \quad [y^3_n, p_3] = \frac{j}{2} x^3_n, \quad [w_2, y^3_m] = \frac{k}{2} x^3_m, \quad [x^2_m, p_3] = \frac{k}{2} x^3_n, \quad [p_1, w_2] = kw_3, \quad [p_1, p_2] = jw_3, \quad [w_2, p_3] = kw_1, \quad [p_2, p_3] = jw_1, \quad [p_1, p_3] = +(jw_2 + k p_2), \\
[p_1, y^1_m] = -\frac{k j}{6} \sum_{l} x^{l + 3}_n x^{i - 3}_n - \frac{k j}{6} \sum_{l} x^{l + 3}_n x^{i - 3}_n, \\
[y^1_n, p_1] = \frac{k j}{6} \sum_{l} x^{l + 3}_n x^{i - 3}_n, \\
[p_1, y^3_m] = \frac{k j}{6} \sum_{l} x^{l + 3}_n x^{i - 3}_n + \frac{1}{2} (ky^2_m + jx^2_m), \quad [y^3_n, p_3] = \frac{k j}{6} \sum_{l} x^{l + 3}_n x^{i - 3}_n + \frac{1}{2} (ky^2_n + jx^2_n), \\
[p_3, y^3_m] = -\frac{k j}{6} \sum_{l} x^{l + 3}_n x^{i - 3}_n, \quad [y^3_n, p_3] = \frac{k j}{6} \sum_{l} x^{l + 3}_n x^{i - 3}_n. \]
Proof. The commutation relations above follow from the fields definition (26) and the algebraic relations given in the theorem 4.1. The computation to check the Jacobi identity is long but also straightforward, here we record the most complicated part:

\[
[y^1_n, [y^1_n, y^1_m]] = \frac{1}{2} \left( k j x^3_{\ell+n+m} \left( \frac{1}{\ell} + \frac{1}{m+n} \right) + k j w_2 \frac{\delta_{\ell-n-m}}{\ell^2} \right) \left( \frac{1}{n} + \frac{1}{m} \right) - k j x^3_{\ell} \frac{\delta_{n-m}}{m^2} = \frac{1}{2} \left( k j x^3_{\ell+n+m} \left( \frac{1}{\ell} + \frac{1}{m+n} \right) + k j w_2 \frac{\delta_{\ell-n-m}}{\ell^2} \right) \left( \frac{1}{n} + \frac{1}{m} \right) - k j x^3_{\ell} \frac{\delta_{n-m}}{m^2} \\
- 2 k j w_3 \delta_{\ell,0} \frac{\delta_{n-m}}{m^3} + k j \left( - \frac{1}{m^2} \delta_{\ell,0} x^3_{n-m} - \frac{1}{n^2} \delta_{\ell-n-m} x^3_{m} \right) \\
+ \frac{k j}{2} x^3_{\ell+n+m} \left( \frac{1}{\ell+m} \right) + k j \frac{1}{6} x^3_{\ell+n+m} \left( \frac{1}{m-n} \right)
\]

Therefore we have

\[
[y^1_n, [y^1_n, y^1_m]] + [y^3_m, [y^1_n, y^1_m]] + [y^1_n, [y^3_m, y^1_n]] = 0.
\]

\[\square\]

A From the Hamiltonian formalism to CFT

Until now, we have only considered the Poisson brackets using the vertex algebras formalism (11), now we will also consider the Hamiltonian operator. The Hamiltonian is given by a field \( h(z) = \sum_{n \in \mathbb{Z}} h_n z^{-n-2} \), more specifically, by its zero mode \( h_0 \). The equations of motion for a field \( A(z) = \sum_{n \in \mathbb{Z}} a(n) z^{-n-1} \) are given by

\[
\frac{d}{d\tau} A(z) = [h_0, A(z)] \quad \Rightarrow \quad A(z, \tau) = e^{\tau h_0} A(z) e^{-\tau h_0} = \sum_{n \in \mathbb{Z}} a(n)(\tau) z^{-n-1}.
\] (28)

Because of \( A(z, 0) = A(z) \) and \( B(z, 0) = B(z) \), we know the brackets relations in \( \tau = 0 \) for the fields \( A(z, \tau) \) and \( B(z, \tau) \). On the other hand, for an arbitrary \( \tau \) the brackets depend on the equations of motion that in general could be hard to solve.

Now, it could happen that for some cases the theory satisfies extra properties. For example, the beta equations that give us a CFT. In this case, some fields are described into two chiral
parts\textsuperscript{9} which depend on $\zeta = e^{r+i\sigma}$ and $\bar{\zeta} = e^{r-i\sigma}$. This means, we will have fields $C(z) = \sum_{n \in \mathbb{Z}} c(n) z^{-n-1}$ and $D(z) = \sum_{n \in \mathbb{Z}} d(n) z^{-n-1}$ such that the equations of motion give

$$
\begin{cases}
C(\zeta) := C(z, \tau) = \sum_{n \in \mathbb{Z}} c(n)(\tau) z^{-n-1} = \sum_{n \in \mathbb{Z}} c(n) \zeta^{-n-1} \\
D(\bar{\zeta}) := D(z, \tau) = \sum_{n \in \mathbb{Z}} d(n)(\tau) z^{-n-1} = \sum_{n \in \mathbb{Z}} d(n) \bar{\zeta}^{-n-1}
\end{cases}
$$

and $[C(\zeta), D(\bar{\zeta})] = 0$, (29)

i.e. the modes of the fields are diagonal for the Hamiltonian. Note that we know the brackets between these kind of fields since we already know the algebra of their modes.

A.1 Torus case

On the $\mathbb{T}^3$ torus case, we can consider the Hamiltonian\textsuperscript{10} as the zero mode of the field $h(z) = \partial_x z_1(z) \partial_x x_1(z) + \partial_x y_1(z) \partial_x y_1(z)$. In this case, we have a CFT. We are interested in the particular fields\textsuperscript{11} $C(z) := \partial_x y_1(z) + \partial_x x_1(z)$ and $D(z) := \partial_x y_1(z) - \partial_x x_1(z)$, they satisfy the conditions in (29). In particular, we can use these fields to describe the fields $x(z, \tau) = x(\zeta, \bar{\zeta}) = x'(\zeta) + x''(\bar{\zeta})$ such that $\partial_{\zeta} x' = C(\zeta)$ and $\partial_{\bar{\zeta}} x'' = D(\bar{\zeta})$ using the notation in (5), we have

$$
\begin{align*}
[x'_i(\zeta), x'_j(\omega)] &= \delta_{ij} 2\log(\zeta - \omega) \\
[x'_i(\zeta), x''_j(\omega)] &= 0 \\
[x''_i(\zeta), x''_j(\omega)] &= \delta_{ij} 2\log(\zeta - \omega)
\end{align*}
$$

where $T(\zeta)$ and $T(\bar{\zeta})$ are two copies of the Virasoro algebra with central charge $\dim \mathbb{T}^3 = 3$.

A.2 Twisted torus case

Now for the twisted torus $\mathbb{T}^3$ with $H_j$ flux, the Hamiltonian is given by the zero mode of the field $h(z) = \partial_x z_1(z) \partial_x x_1(z) + \partial_x y_1(z) \partial_x y_1(z)$. In this case, we do not have a CFT. In [2] this case was studied as a perturbative CFT until first order because the beta equations are satisfied until this order. We are interested in the particular\textsuperscript{12} fields

$$C(z) := -\beta_1(z) + \alpha_1(z) + j \epsilon_{ijk} x_j(z)(\beta_k(z) - \alpha_k(z)), \quad D(z) := \beta_1(z) + \alpha_1(z) + j \epsilon_{ijk} x_j(z)(\beta_k(z) + \alpha_k(z)).$$

Where $\epsilon_{ijk}$ is the Levi Civita tensor. These fields satisfy the conditions in (29) until first order in $j$. Therefore, in this approach $j$ loses its topological meaning. We can use these fields to describe the field $y(z, \tau) = y(\zeta, \bar{\zeta}) = y'(\zeta) + y''(\bar{\zeta}) + O(j^2)$ such that $\partial_{\zeta} y' = C(\zeta)$ and $\partial_{\bar{\zeta}} y'' = D(\bar{\zeta})$. In particular, using the notation in (9), we have

$$
\begin{align*}
[y'_i(\zeta), y'_j(\omega)] &= -2\delta_{ij} \log(\zeta - \omega) - j \epsilon_{ijk} [\bar{y}'_k(\zeta) - y'_k(\omega)] \log(\zeta - \omega) - j \kappa^r l(\zeta, \omega) + O(j^2) \\
[y'_i(\zeta), y''_j(\omega)] &= 0 + O(j^2) \\
[y''_i(\zeta), y'_j(\omega)] &= 2\delta_{ij} \log(\zeta - \omega) + j \epsilon_{ijk} [\bar{y}'_k(\zeta) - y'_k(\omega)] \log(\zeta - \omega) - j \kappa^r l(\zeta, \omega) + O(j^2)
\end{align*}
$$

\textsuperscript{9}Physically this comes from the quantization of the conformal symmetry, that gives us the two non-vanishing components of the energy momentum tensor.

\textsuperscript{10}The Hamiltonian could be more general considering a flat metric $G_{ij}$, but here we are considering the simplest case $G_{ij} = \delta_{ij}$.

\textsuperscript{11}We used the fields $y_i(z)$ on the double torus, this matches with the standard description by the relation $\partial_1 y_1(z) = p(z)$.

\textsuperscript{12}We arrive at these fields from the classical theory that we have not considered here.
\[
\begin{aligned}
[\partial_{\xi} y_i(\zeta), \partial_{\omega} y_j(\omega)] &= -2\delta_{ij}\partial_{\omega}\delta(\zeta - \omega) - j\epsilon_{ijk}\partial_{\omega}y_k\delta(\zeta - \omega) + O(j^2) \\
[\partial_{\xi} y_i(\zeta), \partial_{\omega} y_j(\omega)] &= 0 + O(j^2) \\
[\partial_{\xi} y_i(\zeta), \partial_{\omega} y_j(\omega)] &= 2\delta_{ij}\partial_{\omega}\delta(\zeta - \omega) - j\epsilon_{ijk}\partial_{\omega}y_k\delta(\zeta - \omega) + O(j^2)
\end{aligned}
\]

where \( T(\zeta) \) and \( T(\bar{\zeta}) \) are two copies of the Virasoro algebra until first order in \( j \) with central charge \( \dim T^3 = 3 \).

The relations in (31) were found in [2] from a different point of view, we have arrived at this expression using the Hamiltonian interpretation of vertex algebras. Also, the equation in (30) is implicit in their work, they used the correlators language. Finally, for the general case \( k \neq 0 \) and \( j \neq 0 \) the beta equations are not satisfied at any order therefore a similar procedure is not possible in the general case.

### B Proof of the singularity

We will proof that the logarithmic singularities imply that (25) satisfy the commutation relations in (11) for the affine Kac Moody vertex algebra \( V^{1}(h_k,j) \). First, we proof the same result for the example 3.2, \( k = 0 \) and \( j = 1 \).

#### B.1 The double twisted torus case \( k = 0, j = 1 \)

First, we compute the expression that result from differentiate the identity\(^{13}\) \([y_1(z), y_3](w)\) in the theorem (4.1)

\[
[\partial_{\xi} y_i(z), \partial_{w} y_j(w)] = \partial_{w}(\epsilon_{ijk}w^kr l(z, w) + \frac{1}{2}\xi_{ijk}(\hat{x}_k(z) - \hat{x}_k(w))\log(z - w))
\]

\[
= \epsilon_{ijk}w^k(-\frac{1}{2}(\log z - \log w)\partial_w\delta(z, w)) + \frac{1}{2}(-\partial_z\hat{x}_3(z) - \partial_w\hat{x}_3(w))\delta(z, w) + \frac{1}{2}(\hat{x}_3(z) - \hat{x}_3(w))\partial_w\delta(z, w).
\]

Then we compute the same expression using the equations (25)

\[
[\partial_{\xi} y_i(z), \partial_{w} y_j(w)] = [\beta_1(z) + \frac{1}{2}x_2\partial_zx_3(z) - \frac{1}{2}x_3\partial_zx_2(z), \beta_2(z) + \frac{1}{2}x_3\partial_zx_1(z) - \frac{1}{2}x_1\partial_zx_3(z)]
\]

\[
= \alpha_3(w)\delta(z, w) + \frac{1}{2}x_3(w)\partial_w\delta(z, w) - \frac{1}{2}\delta(z, w)\partial_wx_3(w) - \frac{1}{2}\delta(z, w)\partial_w\delta(z, w),
\]

where we used that \([x_2(z), \beta_2(w)] = [x_2(z), \partial_w y_2(w)] = -\delta(z, w)\) and in the same way \([\beta_1(z), x_1(w)] = \delta(z, w)\).

The fact that these two results are the same follows from the next theorem

**Theorem B.1.** Let \( a(z) \) be a formal distribution and let \( N \) be a non-negative integer. Then one has the following equality of formal distributions in \( z \) and \( w \):

\[
\partial_{w}^N\delta(z - w)a(z) = \partial_{w}^N\delta(z - w)\sum_{j=0}^{N} \partial^j a(w)(z - w)^j
\]

See [10] for a proof of this theorem.

\(^{13}\)Note that we have the identities

\[
\partial_{w}\log(z - w) = -\partial_w\log(z - w) = \delta(z, w), \quad \partial_{w}\partial_z r l(z, w) = -\frac{1}{2}(\log z - \log w)\partial_w\delta(z, w)
\]
B.2 General case

First, we compute the expression that results from differentiate the identity\(^{14}\) of theorem 4.1

\[
\partial_z \partial_w [y_1(z), y_3(w)] = \\
= -\frac{j}{2} w_2 (-\log z - \log w) \partial_w \delta(z, w) + \frac{j}{2} (\partial_z \hat{x}_2(z) + \partial_w \hat{x}_2(w)) \delta(z, w) + \frac{j}{2} (\hat{x}_2(w) - \hat{x}_2(z)) \partial_w \delta(z, w) \\
- \frac{k}{2} y_2 (-\log z - \log w) \partial_w \delta(z, w)) + \frac{k}{2} (\partial_z \hat{y}_2(z) + \partial_w \hat{y}_2(w)) \delta(z, w) + \frac{k}{2} (\hat{y}_2(w) - \hat{y}_2(z)) \partial_w \delta(z, w) \\
+ \frac{kj}{6} (x_3(z)x_1(z) + x_3(w)x_1(w)) \partial_w \delta(z, w) + \frac{kj}{6} (\partial_w x_3(w)x_1(w)) - \partial_z (x_3(z)x_1(z)) \delta(z, w) \\
- \frac{kj}{2} (\partial_z \hat{x}_3(z) \partial_w \hat{x}_1(w) \log(z - w) + \hat{x}_3(z) \partial_w \hat{x}_1(w) \delta(z, w) - \partial_z \hat{x}_3(z) \hat{x}_1(w) \delta(z, w) + \hat{x}_3(z) \hat{x}_1(w) \partial_w \delta(z, w)) \\
- \frac{kj}{2} (w_3 \partial_z \hat{x}_1(z) \log z + w_1 \partial_w \hat{x}_3(w) \log w) \delta(z, w) - \frac{kj}{2} (w_3 \hat{x}_1(z) \log z + w_1 \hat{x}_3(w) \log w) \partial_w \delta(z, w) \\
+ kj (w_1 \partial_z \hat{x}_3(z) - w_3 \hat{x}_1(w)) (-\frac{1}{2w} \log(z - w) + \frac{1}{2} (\log z - \log w) \delta(z, w)) \\
- kj (w_3 \partial_w \hat{x}_1(w) (-\frac{1}{2z} \log(z - w) - \frac{1}{2} (\log z - \log w) \delta(z, w)) \\
+ k j w_3 \partial_z \hat{x}_1(z) (-\frac{1}{2} (\log z - \log w) \delta(z, w)) \\
- k j w_3 \partial_w \hat{x}_1(w) (-\frac{3}{6wz} \log(z - w) + \frac{1}{2} \log z \log w \delta(z, w))
\]

Then we compute the same expression using the equations in \((25)\)

\[
[\partial_z y_1(z), \partial_w y_3(w)] = \\
= -(j \alpha_2(w) + k \beta_2(w)) \delta(z, w) + \frac{j}{2} (\partial_w x_2(w) + \partial_z x_2(z)) \delta(z, w) + \frac{k}{2} (x_2(z) - x_2(w) \partial_w \delta(z, w)) \\
\frac{j}{2} (\partial_w x_2(w) \delta(z, w) - x_2(w) \partial_w \delta(z, w)) + \frac{k}{2} (\partial_w y_2(w) \delta(z, w) - y_2(w) \partial_w \delta(z, w)) \\
\frac{kj}{2} ((x_1(w) \partial_w x_3(w) - x_3(w) \partial_w x_1(w)) \delta(z, w) + x_1(w) x_3(w) \partial_w \delta(z, w)) \\
\frac{j}{2} (\partial_z x_2(z) \delta(z, w) + x_2(z) \partial_w \delta(z, w)) + \frac{k}{2} (\partial_z y_2(z) \delta(z, w) + y_2(z) \partial_w \delta(z, w)) \\
\frac{kj}{2} ((x_1(z) \partial_z x_3(z) - x_3(z) \partial_z x_1(z)) \delta(z, w) + x_1(z) x_3(z) \partial_w \delta(z, w)) \\
\frac{kj}{3} ((2x_1(w) \partial_w x_3(w) - x_3(w) \partial_w x_1(w)) \delta(z, w) - x_3(w) x_1(w) \partial_w \delta(z, w)) \\
\frac{kj}{3} ((-2x_3(z) \partial_w x_1(z) + x_1(z) \partial_w x_3(z)) \delta(z, w) - x_3(z) x_1(z) \partial_w \delta(z, w)) \\
\frac{kj}{2} (-\partial_x \partial_z x_1(w) \delta(z, w) - x_3(z) x_1(w) \delta(z, w) - \partial_z x_3(z) \partial_w x_1(w) \log(z - w) + x_3(z) \partial_w x_1(w) \delta(z, w)),
\]

\(^{14}\)Note that we have the identities

\[
\partial_z r_1(z, w) = \frac{1}{2} \log(z - w) - \frac{1}{2} (\log z - \log w) \delta(z, w)
\]

\[
\partial_z \partial_w t(z, w) = -\frac{1}{6} (\log z - \log w) (\frac{1}{2} \delta(z, w)) + \frac{1}{3} \left( \frac{3}{wz} \log(z - w) \right) - \frac{1}{6} (\log z^2 - 3 \log z \log w + \log w^2) \partial_w \delta(z, w)
\]

17
where we used that $[\beta_1(z), x_2(w)] = \frac{k}{2} x_3(w) \delta(z, w)$ and $[\beta_1(z), y_2(w)] = \frac{j}{2} x_3(w) \delta(z, w)$ and in the same way $[x_2(z), \beta_3(w)] = \frac{k}{2} x_1(z) \delta(z, w)$ and $[y_2(z), \beta_3(w)] = \frac{j}{2} x_1(z) \delta(z, w)$.

The fact that these two results are the same follows from theorem B.1.
