**Abstract**

RNA splicing is a major regulatory mechanism for controlling eukaryotic gene expression. By generating various splice isoforms from a single pre-mRNA, alternative splicing plays a key role in promoting the evolving complexity of metazoans. Numerous splicing factors have been identified. However, the *in vivo* functions of many splicing factors remain to be understood. *In vivo* studies are essential for understanding the molecular mechanisms of RNA splicing and the biology of numerous RNA splicing-related diseases. We previously isolated a *Caenorhabditis elegans* mutant defective in an essential gene from a genetic screen for suppressors of the rubberband *Unc* phenotype of *unc-93(e1500)* animals. This mutant contains missense mutations in two adjacent codons of the *C. elegans* microfibrillar-associated protein 1 gene *mfap-1*. *mfap-1*(n4564 n5214) suppresses the *Unc* phenotypes of different rubberband *Unc* mutants in a pattern similar to that of mutations in the splicing factor genes *uaf-1* (the *C. elegans* U2AF large subunit gene) and *sfa-1* (the *C. elegans* SF1/BBP gene). We used the endogenous gene *tos-1* as a reporter for splicing and detected increased intron 1 retention and exon 3 skipping of *tos-1* transcripts in *mfap-1*(n4564 n5214) animals. Using a yeast two-hybrid screen, we isolated splicing factors as potential MFAP-1 interactors. Our studies indicate that *C. elegans* *mfap-1* encodes a splicing factor that can affect alternative splicing.

**Introduction**

RNA splicing removes non-coding introns and joins adjacent coding exons from pre-mRNAs to generate functional coding mRNAs. Alternative splicing can generate numerous splice isoforms from the same pre-mRNA [1]. The complex proteome encoded by mRNA splice isoforms is believed to be a major driving force for the evolving complexity of metazoans [1,2]. Numerous proteins and non-coding RNAs regulate RNA splicing [3]. The U1 snRNP complex and the SF1/U2AF65/U2AF35 protein complex recognize the 5’ and 3’ splice sites of an intron, respectively [4–11], and the U2 and U4/U5/U6 snRNP complexes assemble in a step-wise manner and undergo compositional and conformational rearrangements to drive the two steps of the trans-esterification reaction in RNA splicing [7,12]. Mutations in trans-splicing factors or co-regulatory splicing elements cause numerous diseases [13,14].

Over 200 protein factors have been shown to regulate splicing or associate with the splicing machinery or other splicing factors [3]. Splicing factors have been identified mostly using biochemical approaches, and the *in vivo* functions of many splicing factors remain largely unknown. *In vivo* analysis of these factors remains a challenge, since many are essential for viability and the analyses of their *in vivo* functions can be limited by the lethality caused by mutations in these factors.

Recent studies indicate that conclusions concerning splicing factors derived from *in vitro* analyses should be complemented by *in vivo* analyses. For example, *in vitro* studies suggest that the splicing factor SF1/BBP, once thought to be ubiquitously required for splicing, might be required for the splicing of only a subset of genes [15–17]. Some *Saccharomyces cerevisiae* core splicing factors, once thought to be essential for the splicing of all introns, were found to affect splicing of only a subgroup of introns when the effects of loss-of-function mutations in these factors were examined [18]. Also, the functions of some splicing factors extend beyond regulating RNA splicing. For example, the U2AF large subunit is required for the efficient export of intronless mRNAs in *Drosophila* in addition to its essential role in regulating 3’ splice site recognition [19]. Thus, *in vivo* functional analyses are essential for an accurate understanding of the biological functions of splicing factors.

In *Caenorhabditis elegans*, the genes *unc-93*, *sup-9* and *sup-10* encode components of a presumptive two-pore domain K+ channel complex that affects muscle activity [20–23]. Animals carrying rare gain-of-function (gf) mutations in any of these three genes are sluggish, defective in egg laying and exhibit a rubberband phenotype: when touched on the head, the animal contracts and relaxes along its entire body without moving backwards. Complete loss-of-function (lf) mutations of *unc-93*, *sup-9* or *sup-10* do not cause obvious abnormalities [21,22]. The SUP-
RNA splicing removes intervening intronic sequences from pre-mRNA transcripts and joins adjacent exonic sequences to generate functional messenger RNAs. The in vivo functions of numerous factors that regulate splicing remain to be understood. From a genetic screen for suppressors of the rubberband Unc phenotype caused by the Caenorhabditis elegans unc-93(e1500) mutation, we isolated a mutation that affects a highly conserved essential gene, mafp-1. Mafp-1 is a nuclear protein that is broadly expressed. Mafp-1 can affect the alternative splicing of the tos-1, an endogenous reporter gene for splicing, and is required for the altered splicing at a cryptic 3′ splice site of tos-1. mafp-1 enhances the effects of the gene uaf-1 (splicing factor U2AF large subunit) in suppressing the rubberband Unc phenotype of unc-93(e1500) animals. Our studies provide in vivo evidence that Mafp-1 functions as a splicing factor.

### Results

**n4564 n5214 suppresses the rubberband Unc phenotype of unc-93(e1500) animals**

Previously we performed a genetic screen for mutations that caused sterility and/or lethality and concurrently suppressed the rubberband Unc phenotype caused by the unc-93(e1500) mutation [29]. Besides uaf-1(n4564) and sfa-1(n4562), we also isolated the mutation n4564 [29], which we renamed n4564 n5214 in this study (see below). Although the precise mechanisms underlying the suppression of the rubberband Unc phenotypes by the uaf-1, sfa-1 [29] and n4564 n5214 (see below) mutations remain to be determined, the uaf-1 and sfa-1 mutations isolated and the splicing of the pre-mRNA of an unknown gene [29]. We identified the pre-mRNA of the gene tos-1 as abnormally spliced in uaf-1 and sfa-1 mutants and determined that tos-1 is a sensitive endogenous reporter for analyzing in vivo functions of splicing factors [30]. In this study, we describe a third isolate, n4564 n5214, from the genetic screen in which we identified the uaf-1 and sfa-1 mutations [29]. We found that the gene affected by n4564 n5214 encodes a novel splicing factor that affects alternative splicing in C. elegans.

**n4564 n5214 contains two missense mutations in the gene mafp-1, which encodes a highly conserved nuclear protein**

We cloned the gene affected by n4564 n5214 by genetic mapping and transgene rescue experiments (Figure 1A, 1B; see Materials and Methods). The n4564 n5214 strain contains two missense mutations in the gene F43G9.10, changing the adjacent conserved amino acids Asp 426 and Thr 427 to Val (n4564) and Ala (n5214) in the predicted protein, respectively (Figure 1C). F43G9.10 encodes the C. elegans ortholog of a highly conserved mammalian protein that has been called “microfibrillar-associated protein 1” (41% identity between the C. elegans and human orthologs) (Figure 1D). We named MFAP-1 Affects Alternative Splicing.

### Table 1. Suppression of the rubberband Unc phenotype by mafp-1 mutations.

| Genotype | Bodybends per 30 sec (± SD) | n |
|----------|----------------------------|---|
| wild-type | 21.8±3.4 | 20 |
| wild-type (25 °C) | 28.3±4.4 | 20 |
| unc-93(e1500) | 0.9±1.3 | 20 |
| unc-93(e1500) (25 °C) | 0.8±0.8 | 20 |
| unc-93(n200) [29] | 15.6±3.5 | 20 |
| sup-10(n983) [29] | 4.3±1.9 | 20 |
| sup-9(n1550); sup-18(n1014) [29] | 0.1±0.4 | 20 |
| mafp-1(n4564 n5214) | 27.1±2.2 | 20 |
| mafp-1(n5214) | 28.4±3.3 | 20 |
| mafp-1(n5214) (25 °C) | 28.3±4.0 | 20 |
| mafp-1(n4564 n5214); unc-93(e1500) | 21.8±4.5 | 20 |
| mafp-1(n4564 n5214); unc-93(n200) | 13.9±3.0 | 20 |
| mafp-1(n4564 n5214); sup-10(n983) | 18.0±4.1 | 20 |
| mafp-1(n4564 n5214); sup-9(n1550); sup-18(n1014) | 0.3±0.5 | 20 |
| mafp-1(n5214); unc-93(e1500) | 1.8±1.3 | 20 |
| mafp-1(n5214); unc-93(e1500) (25 °C) | 8.0±3.6 | 20 |

1.8±1.3 20

**n4564 n5214 weakly suppressed the Unc phenotype of unc-93(e1500) animals at 15°C (L. Ma and H. R. Horvitz, unpublished observations) and was a stronger suppressor at 20°C (Table 1). n4564 n5214/+; unc-93(e1500) animals were as Unc as unc-93(e1500) animals (L. Ma and H. R. Horvitz, unpublished observations), indicating that n4564 n5214 is a recessive suppressor of the Unc phenotype of unc-93(e1500) animals and suggesting that n4564 n5214 causes a reduction or loss of mafp-1 function. We tested whether n4564 n5214 also suppressed the Unc phenotype caused by the rubberband mutants unc-93(n200), sup-9(n1550) and sup-10(n983), n200 is a weakly semi-dominant unc-93 allele that causes a weak rubberband Unc phenotype [22]. The sup-9(n1550) and sup-10(n983) gain-of-function mutations cause strong and moderate rubberband Unc phenotypes, respectively [20,21,23,31]. n4564 n5214 strongly suppressed sup-10(n983) but did not suppress unc-93(n200) or sup-9(n1550) (Table 1). Thus, n4564 n5214 suppressed the same rubberband Unc mutants as do the uaf-1(n4560) and sfa-1(n4562) mutations, both of which suppress the rubberband Unc phenotypes of unc-93(e1500) and sup-9(n983) animals but not the rubberband Unc phenotypes of unc-93(n200) or sup-9(n1550) animals [29].

Plasmids and strains were obtained from the C. elegans Genetic Stock Center (CGC) at The Jackson Laboratory (Bar Harbor, ME) and the Caenorhabditis Genetics Center (CGC, St. Paul, MN) (http://www.c elegansgenetics.org). C. elegans were maintained on NGM plates seeded with E. coli OP50 at 20°C. Nematodes were synchronized by a heat shock and the development of L2-stage larvae was arrested by growth on plates at 25°C. C. elegans were transferred onto fresh plates at 15°C every day until the L4 stage and then grown to adulthood at 20°C. During all experiments, control animals were maintained at 20°C. Animals were assessed at the same time of day. The C. elegans strains and plasmids used in this study are listed in Table S1. All experiments were repeated at least three times and the data were statistically analyzed using GraphPad software (GraphPad Prism, San Diego, CA). The significance of the results was determined by Student’s t-test.
protein 1). The chicken reduction or loss of mfap-1(tm3456 homozygotes is caused by the tm3456 mutation and retained the D426V (A427T) mutation. As expected, both mfap-1(n4564 n5214) and mfap-1(n4588 n5127) double mutants were viable at 20°C, and mfap-1(n4564 n5214); uaf-1(n4588) double mutants were viable at 15°C and became sterile at 20°C, and mfap-1(n4564 n5214); uaf-1(n4588) mutants were likely inviable at both 15°C and 20°C, since we failed to obtain progeny with this genotype from mfap-1(n4564 n5214)+/+; uaf-1(n4588)+/+ hermaphrodites (Table 3). All viable mfap-1; uaf-1 multiple mutant animals exhibited strong suppression of the unc-93(e1500) Unc phenotype, similar to that of the mfap-1(n4564 n5214) mutant animals (Table 3). That mfap-1; uaf-1 multiple mutant animals, except mfap-1(n4564 n5214); uaf-1(n5123), exhibited a stronger temperature-sensitive sterile or lethal phenotype than either mfap-1 or uaf-1 mutant animals suggests that the mfap-1(n4564 n5214) and uaf-1 mutations might have additive effects on animal survival.

We next examined whether mfap-1(n5214) could enhance the suppressor activities of mfap-1 mutations for the Unc phenotype of unc-93(e1500) animals by generating mfap-1(n5214); uaf-1 double mutant animals carrying the unc-93(e1500) mutation (Table 3). mfap-1(n5214); uaf-1(n5123) double mutants were similar to mfap-1(n5214) or uaf-1(n5123) single mutants and were not substantially suppressed for the Unc phenotype of unc-93(e1500) animals (Table 3). mfap-1(n5214) enhanced the suppressor activity of the unc-93(e1500) animals, since both mfap-1(n5214); uaf-1(n5123) and mfap-1(n5214); uaf-1(n5123) strongly suppressed unc-93(e1500), since both unc-93(e1500) and uaf-1(n5123) are strong suppressors for unc-93(e1500) [29]. Although mfap-1(n5214) or uaf-1(n5123) mutants were apparently healthy at 20°C, mfap-1(n5214); uaf-1(n5123) mutant animals became partially sterile at 20°C (L. Ma and H. R. Horvitz, unpublished observations). Furthermore, mfap-1(n5214); uaf-1(n5123) double mutant animals were viable at 15°C but became sterile when grown at 20°C, which is a more severe temperature-sensitive phenotype than that of uaf-1(n5123) single mutants. That mfap-1 mutations enhance the temperature-sensitive phenotypes of uaf-1 mutants suggests that mfap-1 and uaf-1 might act in parallel in affecting unc-93 function and animal survival.

We tested if mfap-1(n4564 n5214), like the uaf-1(n5488) mutation [29], would cause the recognition of a cryptic 3’ splice site in exon 9 of unc-93(e1500). We did not observe any obviously altered recognition of this cryptic 3’ splice site (1.3% for wild type vs. 2% for mfap-1(n4564 n5214) animals) (Figure S1). Therefore, the suppression of the Unc phenotype of unc-93(e1500) by mfap-1(n4564 n5214) might not be caused by altered splicing of the unc-93(e1500) transcript.

mfap-1(n4564 n5214) alters the splicing of tos-1 by increasing intron 1 retention and exon 3 skipping

To analyze whether mfap-1 can affect alternative splicing, we examined the splicing of tos-1 in mfap-1(n4564 n5214) animals. We previously described tos-1 as a sensitive endogenous reporter for alternative splicing in C. elegans [30]. As shown in Figure 3A–3C, mfap-1(n4564 n5214) increased tos-1 intron 1 retention and exon 3 skipping, suggesting that the recognition of the 3’ splice sites in intron 1 or before exon 3 was reduced in mfap-1(n4564 n5214) animals. We note that the tos-1 splice isoforms we observed in mfap-1(n4564 n5214) and mfap-1(RNAi) animals can also be seen in wild-type animals (Figure 3A), indicating that alterations in mfap-1

The D426V(n5214) and T427A(n4564) mutations act together to suppress unc-93(e1500)

The temperature-sensitive lethal phenotype of mfap-1(n4564 n5214) at 25°C provided an approach to the identification of genes that interact with mfap-1 by seeking suppressors of the temperature-sensitive lethality. We screened about 50,000 haploid genomes and identified two independent suppressors, which we later found to cause the same intragenic change in mfap-1 [see Materials and Methods]. Specifically, both suppressors caused a reversion of the T427A (n4564) mutation (see Materials and Methods) to the wild-type codon (ACA) and amino acid (A427T) and retained the D426V(n5214) mutation. mfap-1(n5214) did not obviously suppress the rubberband Unc phenotype of unc-93(e1500) animals at 20°C but did do so at 25°C (Table 1), indicating that mfap-1(n5214) is a temperature-sensitive allele.

We examined how the two mfap-1 mutations, n4564 and n5214, contribute to the activity of mfap-1(n4564 n5214) as a suppressor of the Unc phenotype of unc-93(e1500) animals. We expressed MFAP-1::GFP fusion transgenes containing the n4564 (T427A) mutation, the n5214 (D426V) mutation or both mutations in the body-wall muscles of mfap-1(n4564 n5214); unc-93(e1500) animals and assayed the locomotion of transgenic animals (Table 2). Both the mfap-1(n4564):GFP and the mfap-1(n5214):GFP transgenes greatly rescued the suppression of unc-93(e1500) by mfap-1(n4564 n5214), while the mfap-1(n4564 n5214):GFP transgene only partially rescued the suppression (Table 2). These results suggest that individually the mutations n4564 or n5214 only slightly if at all affect the function of mfap-1 and that the strong suppression of unc-93(e1500) by mfap-1(n4564 n5214) probably results from an additive or synergistic effect of these two mutations, likely in reducing mfap-1 function.
Figure 1. Genetic mapping, cloning, and identification of mfap-1. (A) Genomic location of the n4564 n5214 mutation based on genetic mapping using visible markers and SNPs (e.g., SNP T01H8: 7110 on the left and SNP F36A2: 3334 on the right). Cosmids tested in rescue experiments are labeled. Only cosmids F43G9 rescued the three phenotypic characteristics of mfap-(n4564 n5214) individuals: suppression of the Unc phenotype of unc-93(e1500) animals; partial sterility at 20°C; and temperature-sensitive lethality at 25°C. (B) Transgene rescue experiments. Transgenes (nEx) were injected into the gonads of mfap-1(n4564 n5214); unc-93(e1500) animals, and lines stably transmitting the transgenes were established. Transgenic lines were analyzed for the rescue of each of three abnormalities: suppression of the Unc phenotype of unc-93(e1500) animals; partial sterility at 20°C; and temperature-sensitive lethality at 25°C. (C) Gene structure of mfap-1. Black boxes: coding exons. Open boxes: 5' and 3' UTRs. Positions of start (ATG) and stop codons (TGA) are indicated. The sites of the n4564 n5214 mutation, the n5214 mutation and the tm3456Δ deletion are labeled. (D) Sequence alignment of predicted MFAP-1 proteins from C. elegans, Drosophila, chicken and human. *: amino acids

| Genotype | Rescue Lines/Total Lines | Locomotion | Sterility | Ts Lethality (25°C) |
|----------|--------------------------|------------|-----------|---------------------|
| n4564 n5214; unc-93(e1500); nEx[F43G9] | 4/4 | 1/4 | 1 (partial)/4 |
| n4564 n5214; unc-93(e1500); nEx[map-1] | 2/2 | 2/2 | 2 (partial)/2 |

nullated in mfap-1(n4564 n5214) mutants. Amino acids conserved in at least three orthologs are darkly shaded, while amino acids with similar physical properties or conserved in two orthologs are lightly shaded.

doi:10.1371/journal.pgen.1002827.g001

Figure 2. MFAP-1 is a nuclear protein expressed in multiple tissues. (A) A 2.5 kb 5′ promoter region upstream of the start codon of mfap-1 was used to drive the expression of a transcriptional fusion GFP reporter in transgenic animals. The tissues in which the GFP reporter was expressed are labeled. This figure shows a montage of two photographs, which were pseudo-colored from a gray-scale image to a green-scale image using Adobe Photoshop to reflect the level of GFP expression. (B) Transgene experiments were performed as described in Materials and Methods. The C. elegans MFAP-1::GFP fusion protein, when expressed in body-wall muscles using a myo-3 promoter in either wild-type or mfap-1(n4564 n5214) animals of mixed developmental stages, was exclusively localized in nuclei (left and middle panels). Similarly, human MFAP-1::GFP fusion protein, when expressed in the body-wall muscles of mfap-1(n4564 n5214) animals, was also exclusively localized in nuclei (right panels). Lower panels show typical nuclear GFP signals in adult transgenic animals. Genetic backgrounds and transgenes are indicated.

doi:10.1371/journal.pgen.1002827.g002

affect tos-1 alternative splicing events that occur in the wild type. We also examined whether mfap-1(n4564 n5214) could cause recognition of the cryptic 3′ splice site in tos-1 intron 1, which was recognized in uaf-1(n4588) animals [30]. We did not detect obvious recognition of the cryptic 3’ splice sites in mfap-1(n4564 n5214) animals (Figure 3D), suggesting that mfap-1(n4564 n5214) did not alter the specificity of 3′ splice-site recognition. We similarly examined mfap-1(n5214) animals and did not observe obvious effects on the splicing of tos-1 or the recognition of the intron 1 cryptic 3′ splice site (Figure S2B), suggesting that mfap-1(n5214) does not alter or has a very weak effect on tos-1 splicing. This result is consistent with the notion that n5214 is a weaker mfap-1 allele than n4564 n5214.

We next examined the splicing of tos-1 in animals fed dsRNA targeting mfap-1. We observed an apparent increase of tos-1 isoforms 1 and 2 (Figure 4A). Increased expression of isoforms 1 and 2 is caused by increased intron 1 retention and exon 3 skipping in tos-1 splicing, as was seen for mfap-1(n4564 n5214)
MFAP-1 interacts physically with known splicing factors in a yeast two-hybrid experiment

To further understand the function of MFAP-1, we sought to identify interacting proteins of MFAP-1 using a yeast two-hybrid screen (see Materials and Methods). We isolated and retested nine genes encoding proteins that might potentially interact with MFAP-1 (Table S1). Two of the genes, K04G7.11 and D1054.14, encode the C. elegans orthologs of the presumptive splicing factors SYF2 [34] and Prp38 [35]. Drosophila MFAP-1 (dMFAP1) was found to be in a protein complex with dPrp38 in co-immunoprecipitation experiments and to interact with dPrp38 physically [33]. SYF2 mutations were found to cause synthetic lethality with mutations in splicing factors clf1Delta2 and prp17/cdc40Delta in S. cerevisiae [34], and mammalian orthologs of SYF2 were identified in various splicesomal complexes by proteomic approaches [3], suggesting that SYF2 acts as a splicing factor. We also identified MFAP-1 as an interactor in the two-hybrid screen, indicating that MFAP-1 might form homodimers. The other potential interactors are two proteins involved in rRNA processing (C05C8.2 and T22H9.1), a ribosomal protein (RPS-6), a Ras-associated PH-domain containing protein (MIG-10), a Rab11 family-interacting protein 2 (Y39F10B.1) and a protein of unknown function (F43C11.9). Although the interactions between MFAP-1 and the proteins from the yeast two-hybrid screen remain to be verified by other approaches, the observation that two presumptive splicing factors (Prp38 and SYF2) are among the candidates is consistent with our findings and also those of Andersen and Tapon [33] indicating that MFAP-1 might function as a splicing factor.

We next examined the splicing of tos-1 in animals fed dsRNAs targeting mfap-1, D1054.14 and K07G7.11 (Figure 4). We found that D1054.14(RNAi) caused an increase of tos-1 splice isoform 2 similar to that seen in mfap-1(RNAi) animals (Figure S4). No apparent alteration in tos-1 splicing was detected in K07G7.11(RNAi) animals. This result is consistent with previous studies indicating that homologs of D1054.14 can function as splicing factors [33,35] and identified tos-1 as a target of D1054.14 in C. elegans.

**Table 2.** mfap-1(n4564) and mfap-1(n5214) are weak mutations that act together to suppress the rubberband Unc phenotype of unc-93(e1500) animals.

| Genotype | Bodybends per 30 sec (± SD) | n |
|----------|-----------------------------|---|
| nEx[Pmyo-3 mfap-1 cDNA (wt)::GFP] line 1 | 1.3±1.4 | 20 |
| nEx[Pmyo-3 mfap-1 cDNA (wt)::GFP] line 2 | 2.1±2.1 | 20 |
| nEx[Pmyo-3 mfap-1 cDNA (wt)::GFP] line 3 | 1.7±2.0 | 20 |
| nEx[Pmyo-3 mfap-1 cDNA (n4564)::GFP] line 1 | 1.3±1.1 | 20 |
| nEx[Pmyo-3 mfap-1 cDNA (n4564)::GFP] line 2 | 1.6±1.7 | 20 |
| nEx[Pmyo-3 mfap-1 cDNA (n4564)::GFP] line 3 | 3.8±1.4 | 20 |
| nEx[Pmyo-3 mfap-1 cDNA (n5214)::GFP] line 1 | 3.4±1.6 | 20 |

animals (Figure 3). The similarity of mfap-1(n4564 n5214) and mfap-1(RNAi) in affecting tos-1 splicing further suggests that n4564 n5214 causes a reduction or loss of mfap-1 function. Reducing mfap-1 expression by RNAi feeding did not cause the recognition of the cryptic 3′ splice site in intron 1 (Figure 4B). Similarly, that cryptic splice site was not recognized in mfap-1(n4564 n5214) animals (Figure 3D).

To determine whether uaf-1 mutations and mfap-1 mutations could interact in affecting RNA splicing, we examined the splicing of tos-1 and the recognition of the cryptic 3′ splice site of tos-1 intron 1 in mfap-1; uaf-1 mutant animals. For each mfap-1; uaf-1 mutant, the splicing of tos-1 appeared to be similar to that in the corresponding uaf-1 single mutant or mfap-1 single mutant (Figure S2A, S2B, top panels). We did not observe additive or synergetic effects of uaf-1 and mfap-1 mutations on intron 1 retention (Figure S3A, e.g., compare mfap-1(n4588 n5127) with mfap-1(n4564 n5214); uaf-1(n4588 n5127) or exon 3 skipping (Figure S3B, e.g., compare mfap-1(n4564 n5214) with mfap-1(n4564 n5214); uaf-1(n4588 n5127)). Interestingly, the recognition of the cryptic 3′ splice site was reduced by about 50% in mfap-1(n4564 n5214); uaf-1(n4588 n5127) and mfap-1(n5214); uaf-1(n4588 n5127) mutant animals compared to that in uaf-1(n4588 n5127) mutant animals (Figure S2A, S2B, bottom panels and Figure S3C), suggesting that wild-type mfap-1 function might be required for the recognition of the cryptic 3′ splice site in uaf-1(n4588 n5127) animals.
Discussion

MFAP-1 is essential for animal development

MFAP1 was initially identified as a putative extracellular matrix protein based on a screen of embryonic chicken cDNA expression library using antibodies against elastic fiber microfibrils-enriched bovine ocular zonule proteins [32]. Our analysis of C. elegans mfap-1 and the study of the Drosophila ortholog dMFAP1 [33] indicate that MFAP-1 orthologs in these two species are nuclear proteins that affect RNA splicing. In addition, the human ortholog of MFAP-1 was found to be associated with spliceosomes by mass spectrometry analysis [36–38]. Since the human ortholog of mfap-1 can rescue the activity of C. elegans mfap-1(n4564 n5214) for suppressing the Unc phenotype of unc-93(e1500) animals, the function of MFAP-1 is likely conserved from nematodes to humans.

Drosophila dMFAP1 acts with several other splicing factors in G2/M progression during mitosis and affects the ratio of pre-mRNA to mature mRNA of the γ-tubulin gene and the mRNA level of the stg/cdc2e gene [33]. It is not known if dMFAP1 affects alternative splicing [33]. C. elegans mfap-1(n4564 n5214) mutants exhibit a temperature-sensitive phenotype with normal growth at 15°C and embryonic lethality at 25°C; mfap-1(tm3456Δ) homozygous animals arrest at L1 to L2 larval stages at 20°C, and mfap-1 RNAi-treated animals arrest at variable larval stages at 20°C (L-Ma and H. R. Horvitz, unpublished observations). These observations indicate that C. elegans mfap-1 is essential for animal development. Whether the developmental defect of mfap-1-deficient animals is caused by mitotic defects remains to be determined.

MFAP-1 is probably required for the recognition of weak 3’ splice sites

We isolated mfap-1(n4564 n5214) from the same genetic screen in which we identified mutations affecting uaf-1 and sfa-1 [29]. mfap-1(n4564 n5214) suppressed the phenotypes of different rubberband Unc mutants in patterns similar to those of uaf-1(n4588) and sfa-1(n4562) mutations. The findings led us to hypothesize that MFAP-1 might function as a splicing factor. Our analysis of tos-1 splicing in mfap-1 mutant animals and in animals treated with mfap-1 RNAi provided molecular evidence that mfap-1 can affect alternative splicing. mfap-1(n4564 n5214) and mfap-1(RNAi) both increased tos-1 intron 1 retention (with a weak 3’ splice site) and tos-1 exon 3 skipping (with a different weak 3’ splice site), and neither affected the splicing of intron 3 (with a strong consensus 3’ splice site TTTTCAG). These observations suggest that MFAP-1 might be required for the recognition of weak 3’ splice sites and not for the recognition of strong 3’ splice sites. We propose that MFAP-1 can act much like UAF-1 and SFA-1, mutations in which cause reduced recognition of the weak 3’ splice sites in introns 1 and 2 and do not affect the recognition of the consensus 3’ splice site in intron 3 of tos-1 [30]. Similar to sfa-1(n4562), mfap-1(n4564 n5214) or mfap-1(RNAi) did not cause recognition of the cryptic 3’ splice site in tos-1 intron 1, suggesting that MFAP-1 probably is not essential for determining the specificity of 3’ splice sites.

The effects of mfap-1(n4564 n5214) and mfap-1(RNAi) on tos-1 splicing are qualitatively similar but quantitatively different. We also observed differences in the effects on tos-1 splicing by genetic mutations and RNAi treatments in our previous studies of uaf-1 and sfa-1, in which we found that uaf-1(n4588) or sfa-1(n4562) caused more dramatic alterations of tos-1 splicing than did either uaf-1(RNAi) or sfa-1(RNAi). This difference was at least partially caused by an altered function of UAF-1 in uaf-1(n4588) animals [30]. Thus, differing effects on target gene splicing by RNAi-treatment and genetic mutation of a splicing factor gene could be caused by several factors, including the differing level of the splicing factor in RNAi-treated and mutant animals and the effects of mutations on the function of the splicing factor.

MFAP-1 might interact with multiple partners to affect RNA splicing

From a yeast two-hybrid screen, we identified nine candidate MFAP-1-interacting proteins. One, D1054.14, is homologous to the S. cerevisiae splicing factor Prp38 [33]. Another, K04G7.11, is orthologous to the S. cerevisiae candidate splicing factor SYF2 [34]. Drosophila splicing factors DPrp38 and DSFV1 were found in a protein complex with dMFAP1, and DPrp38 interacts with dMFAP1 in GST-pulldown experiments [33]. We did not identify orthologs of SYF1 or several other splicing factors found in the Drosophila dMFAP1 complex, possibly because the co-immunoprecipitation experiments could have identified Drosophila proteins that did not directly interact with dMFAP1, whereas our yeast two-hybrid screen could identify only proteins that directly interact with MFAP-1. Both studies suggest that MFAP-1 interacts with multiple splicing factors directly or indirectly and that MFAP-1 might play multiple roles in affecting RNA splicing.

We found that reducing the expression of D1054.14 by RNAi caused alterations in tos-1 splicing similar to those caused by mfap-1(RNAi) (Figure S4), suggesting that MFAP-1 and D1054.14/PRP38 might interact to regulate the splicing of the same set of genes. We did not identify alterations in tos-1 splicing in animals fed dsRNA targeting K04G7.11, indicating that K04G7.11 might not be required for the splicing of tos-1.

mfap-1 and uaf-1 might interact to affect RNA splicing

We previously concluded that the suppression of the rubberband Unc phenotype of unc-93(e1500) animals by uaf-1(n4588) and sfa-1(n4562) is probably caused by altered splicing of an unknown gene [29]. The splicing of unc-93(e1500) appears to be normal in mfap-1(n4564 n5214) animals, indicating that altered splicing of unc-93(e1500) transcripts similarly is not the cause of the suppression of unc-93(e1500) Unc phenotype by mfap-1(n4564 n5214).

The uaf-1(n4588) mutation likely causes the recognition of the cryptic 3’ splice site of tos-1 intron 1 by altering rather than decreasing the function of the UAF-1 protein [30]. uaf-1(n4588 n5127) is a weaker mutation than uaf-1(n4588), and the recognition of the cryptic 3’ splice site in uaf-1(n4588 n5127) animals but not in uaf-1(n4588) animals was reduced by the presence of the mfap-1(n4564 n5214) and mfap-1(n5214) mutations (Figure S3C). These results suggest that the recognition of the cryptic 3’ splice site of tos-1 requires MFAP-1 only if that recognition is already weak as in uaf-1(n4588 n5127) mutants. These results further support our conclusion that MFAP-1 affects alternative splicing.

In short, we propose that MFAP-1 can act as a splicing factor. Future studies should reveal how MFAP-1 interacts with other splicing factors to affect C. elegans development by regulating splicing of its target genes.

Materials and Methods

Strains

C. elegans strains were grown at 20°C as described unless otherwise indicated [39]. N2 (Bristol) was the reference wild-type strain [39]. Other strains used in the study were:

LGL: mfap-1(n4564 n5214, n5214, tm3456Δ) (this study).
Figure 3. *mfap-1(n4564 n5214) affects the splicing of *tos-1*. (A) RT-PCR experiments showing the effect of *mfap-1(n4564 n5214)* on *tos-1* alternative splicing. *tos-1* splice isoforms are illustrated on the right. (B) The molar ratios of all *tos-1* splice isoforms with intron 1 retention (isoforms 1 and 2), presented as a percentage of all isoforms combined (isoforms 1, 2, 3, 4 and 5). Error bars: standard deviations. *p<0.05. (C) The molar ratios of all *tos-1* splice isoforms with exon 3 skipping (isoforms 2 and 5), presented as a percentage of all isoforms combined (isoforms 1, 2, 3, 4 and 5). Error bars: standard deviations. *p<0.05. (D) RT-PCR experiments showing the effect of the *mfap-1(n4564 n5214)* mutation on the recognition of the cryptic 3' splice site of *tos-1* intron 1. For all analyses, isoform intensities were obtained by analyzing biological duplicates or triplicates using NIH ImageJ software.

LGIV: sfa-1(n4562) [29].
LGX: sup-10(n983) [21].
CB4856 (Hawaiian) [40]

We used the genetic translocation hT2[bl-4(e937) let-7(q792) qIs48] LG I; LG III [41], which carries an integrated pharyngeal GFP element [42], to balance the mfap-1(tm3456) mutation.

Cloning of mfap-1
We used single-nucleotide polymorphism (SNP) mapping [40] to localize n4564 n5214 to the right of nucleotide 7110 (SNP T01H8: 7110 S = AT) on cosmid T01H8 (T01H8 sequences refer to nucleotides of GenBank accession no. Z80219) and to the left of nucleotide 3334 (SNP F36A2: 3334 S = CT) on cosmid F36A2 (F36A2 sequences refer to nucleotides of GenBank accession no. Z81077) (Figure 1A). We isolated 10 Dpy recombinants after crossing dpy-5(e61) n4564 n5214 hermaphrodites with males of the Hawaiian strain CB4856, and six Unc recombinants after crossing n4564 n5214 unc-75(e950) hermaphrodites with CB4856 males.

Cosmid F43G9 rescued three phenotypic characteristics of the n4564 n5214 strain: suppression of unc-93(e1500), partial sterility and temperature-sensitive lethality at 25°C (Figure 1B). We determined the coding sequences of F43G9.10 and identified two missense mutations (GAT-to-GTT (D426V) and ACA-to-GCA (T427A)) in the fourth exon of F43G9.10 (Figure 1C). The predicted proteins encoded by the F43G9.10 orthologs in C. elegans, Drosophila, chicken and human are highly conserved, and the Asp-Thr dipeptide altered in the mfap-1(n4564 n5214) mutant is completely conserved (Figure 1D). A genomic fragment containing a 2.5 kb promoter region, the entire 1.7 kb coding region and a 1.5 kb 3' downstream region exhibited rescuing activity similar to that of the F43G9 cosmid (Figure 1B). Transgenes expressing F43G9.10 and or the human ortholog of F43G9.10 (Hsfap-1) in body-wall muscles each rescued the suppression of unc-93(e1500) by mfap-1(n4564 n5214) (Figure 1B). A transgene carrying the mfap-1(n4564 n5214) mutation (mut) failed to rescue the suppression of unc-93(e1500) by mfap-1(n4564 n5214) (Figure 1B), suggesting that this mutation caused the suppressor activity in mfap-1(n4564 n5214) animals.

Screen for suppressors of mfap-1(n4564 n5214)
Synchronized L4 mfap-1(n4564 n5214) animals (P0) grown at 15°C were mutagenized with ethyl methanesulfonate (EMS) as described [39] and grown to gravid adults at 15°C. The P0 adults were bleached, and their F1 progeny were grown to young adults at 15°C and moved to 25°C. After three days at 25°C, the plates were examined for surviving fertile animals. From about 50,000 haploid genomes (F2) screened, two independent suppressed strains were isolated. As animals with a mfap-1(n4564 n5214) phenotype (partial sterility at 20°C and temperature-sensitive lethality at 25°C) were not identified from about 1800 progeny of mfap-1(n4564 n5214) sup/++ animals, we concluded that the two suppressors were either intragenic or extragenic and very closely linked to mfap-1. DNA sequence determination identified in both suppressors the same...
nucleotide change (GCA to ACA at codon 427), which converted the mutated amino acid alanine in the mfap-1(n4564 n5214) mutant to the wild-type threonine (A27T) while retaining the D426V mutation. One of the two isolates was used for subsequent studies, and the single mutation it carried was designated mfap-1(n5214).

Yeast two-hybrid screen
We used a yeast two-hybrid screen [43,44] to identify proteins that might interact with MFAP-1. A pACT2.2 C. elegans yeast two-hybrid library (Addgene plasmid 11523, provided by Dr. Guy Caldwell) was used to screen for MFAP-1 interactors. For the bait, a full-length mfap-1 cDNA was subcloned into the pGBK T7 plasmid (Clontech) and then transfected into the S. cerevisiae strain PJ69-4A, pGBK T7-mgap-1-positive yeast cells were transfected with 2 μg of DNA from the pACT2.2 yeast two-hybrid library, and cells were grown on a SD-Leu-Trp-His medium with 5 mM 3-AT. Positive clones were picked and grown in separate cultures using the same SD medium. Plasmids were obtained from each clone by the smash-and-grab method [45]. Purified plasmids were transfected into the bacterial strain DH5α and grown on LB-ampicillin plates. Plasmids were purified from the bacterial cultures, and sequences of the inserts were determined. Using yeast two-hybrid assays, we confirmed that these clones did not cause survival of yeast cells transfected with the pGBK T7 empty vector on SD-Leu-Trp-His medium, suggesting that proteins encoded by these clones potentially interact with MFAP-1 but not with the GAL4 DBD domain expressed by the pGBK T7 vector.

RNA interference
Young adult animals were fed HT115 (DE3) bacteria containing plasmids directing the expression of dsRNAs targeting uaf-1, sfa-1, mfap-1, D1054.14 or K04G7.11 on NGM plates with 1 mM IPTG and 0.1 mg/ml Ampicillin [46]. F₁ progeny of these animals, which arrested at various developmental stages, were washed off plates, rinsed with H₂O and resuspended in Trizol (Invitrogen) for preparation of total RNA. The DNA construct that expresses dsRNA targeting uaf-1 and the bacterial strain that expresses dsRNA targeting sfa-1 were described previously [29]. We obtained a bacterial strain expressing dsRNA targeting mfap-1 from a whole-genome RNAi library [47] and bacterial strains expressing dsRNAs targeting mfap-1, D1054.14 or K04G7.11 from an ORFeome-based RNAi library [40]. The sequences of plasmids from single colonies were determined to confirm the presence of coding sequences for each gene.

Body-bend assay
L4 animals were picked 16–24 hrs before being tested. One day later, young adults were individually picked to plates with OP50 bacteria, and body-bends were counted for 30 sec using a dissecting microscope as described [49].

Molecular biology
Total RNA was purified with Trizol (Invitrogen), and cDNA was generated following the protocol provided with the SuperScript II kit (Invitrogen). PCR was performed with Eppendorf Cyclers, and DNA products were resolved using agarose gels. NIH ImageJ software was used to quantify tos-1 splice isoforms [30]. The percentages of tos-1 intron 1 retention, exon 3 skipping and the recognition of the intron 1 cryptic 3' splice were analyzed as described [30]. We performed RT-PCR experiments with animals at different developmental stages and found no indication that tos-1 splicing is regulated developmentally (Figure S5). DNA sequence analysis was performed using an ABI Prism 3100 Genetic Analyzer and an ABI 3730XL DNA Analyzer.

Plasmids
mfap-1 cDNAs were amplified by RT-PCR from wild-type, mfap-1(n4564 n5214) or mfap-1(n3214) animals and subcloned to the pPD93.97 vector in-frame with GFP using BamH I and AgeI restriction sites. For constructs expressing the mfap-1(n4564) transgene, the n4564 mutation was introduced into the pPD93.97::mfap-1 cDNA construct using a QuickChange Site-Directed Mutagenesis Kit (Stratagene) with primers containing the n4564 mutation. For the plasmid used as bait in the yeast two-hybrid screen, full-length mfap-1 cDNA was released from the pGEM-T Easy vector (Promega) with NcoI blunt/PstI and subcloned in-frame into the pGBK T7 vector (Trp1, Kan'') (Clontech) using BamH I blunt/PstI restriction sites. To construct a P_mfap-1::GFP transcriptional fusion transgene, an mfap-1 promoter fragment of about 2.5 kb was amplified using PCR and subcloned into the pPD95.79 vector using PstI/SmaI restriction sites.

Transgene experiments
Microinjection of DNA into the syncytial gonad and the generation of animals with germline transmission of transgenes were performed as described [50] with mfap-1(n4564 n5214) animals grown at 15°C. DNA injection mixtures generally contained 20 μg/ml 1 kb DNA ladder, 20 μg/ml Arabidopsis genomic DNA and 20 μg/ml of the transgene of interest. When the transgene did not express a GFP fusion protein, 20 μg/ml pPD95.86-GFP plasmid (which expresses GFP in body-wall muscles) was added to the injection mixture as a visible fluorescence marker.

Supporting Information
Figure S1 mfap-1(n4564 n5214) does not obviously affect the altered splicing of unc-93(e1500) exon 9. Real-time RT-PCR was performed as described [29] to quantify the recognition of the cryptic 3' splice site of unc-93(e1500) exon 9. No apparent difference between unc-93(e1500) and mfap-1(n4564 n5214); unc-93(e1500) animals was detected. *: results reported previously by Ma and Horvitz (2009) [29]. (TIF)

Figure S2 mfap-1 and uaf-1 mutations do not exhibit additive or synergistic effects on the altered splicing of tos-1. (A) RT-PCR experiments showing the splicing of tos-1 (top panel) or the recognition of the cryptic 3' splice site of tos-1 intron 1 (bottom panel) in mfap-1(n4564 n5214) single or mfap-1(n4564 n5214); uaf-1 mutant animals. Genotypes are indicated at the top, and tos-1 splice isoforms on the right. (B) RT-PCR experiments showing the splicing of tos-1 (top panel) or the recognition of the cryptic 3' splice site of tos-1 intron 1 (bottom panel) in mfap-1(n5214) single or mfap-1(n5214); uaf-1 double mutant animals. Genotypes are indicated at the top, and tos-1 splice isoforms on the right. (TIF)

Figure S3 Quantification of tos-1 intron 1 retention, exon 3 skipping and the recognition of the intron 1 cryptic 3' splice site in mfap-1; uaf-1 multiple mutant animals. (A) The molar ratios of all tos-1 splice isoforms with intron 1 retention, presented as a percentage of all isoforms combined. Error bars: standard deviations. (B) The molar ratios of all tos-1 splice isoforms with exon 3 skipping, presented as a percentage of all isoforms combined. Error bars: standard deviations. (C) Percentages of tos-1 isoforms spliced at the cryptic 3' splice site of tos-1 intron 1
compared to all isoforms spliced at either the endogenous 3′ splice site or the cryptic 3′ splice site. For all analyses, isoform intensities were obtained by analyzing biological duplicates or triplicates using NIH ImageJ software. N.S., no significant difference.

(TIF)

Figure S4 Reducing the expression of mfasf-1 or D1054.14 by RNA interference altered the splicing of tos-1. RT-PCR experiments showing the effects of reducing the expression of mfasf-1, D1054.14 or K04G7.11 by RNAi feeding on tos-1 alternative splicing. mfasf-1(RNAi) and D1054.14(RNAi) caused similar alterations in tos-1 splicing, while K04G7.11(RNAi) did not obviously affect the splicing of tos-1. RNAi bacterial strains were obtained from an ORFeome-based RNAi library [48].

(TIF)

Figure S5 The splicing of tos-1 is not regulated developmentally. RT-PCR experiments examining the splicing of tos-1 in animals at different synchronized developmental stages. tos-1 splicing was similar in all developmental stages examined. Acknowledgments

We thank members of the Horvitz laboratory and the Ma laboratory, especially Anna Corrirom, Nicolas Paquin, Takashi Hirose, Shuo Luo, Dengke Ma, Zhaofa Xu, and Ben Wu, for suggestions. We thank Nicolas Paquin for help with the yeast two-hybrid screen. We thank Na An and Yaoou Zhong for strain maintenance and Rita Droste and Fei Wang for technical support. We thank Andy Fire for providing the pPD plasmids we used for constructing transgene constructs. We thank Shohei Mizani of Tokyo Women’s Medical University for providing the tos-1456A. Some genomic sequences and polymorphisms were identified by the WUSTL Genome Center. Some C. elegans strains were provided by the Caenorhabditis Genetics Center. H. R. Horvitz is the David H. Koch Professor of Biology at MIT and an Investigator of the Howard Hughes Medical Institute.
