Abstract

Background-

Mammary tumors are frequently seen in female dogs. Conventionally, these tumors are diagnosed by histopathology. Differentially expressed biomarkers could aid in non-invasive diagnosis of canine mammary tumors but their number is scanty. The present investigation focuses on assessing HSPD1 as a diagnostic biomarker of canine mammary tumors.

Methods and results-

Expression of \textit{HSPD1} transcript was analyzed by SYBR green based real time PCR (qRT-PCR). Gene encoding immuno-dominant region of HSPD1 was cloned using the expression vector pPROEX-HTa and expressed in a prokaryotic system. Upon purification by affinity chromatography, a 60KDa recombinant protein was obtained which was confirmed by Western blotting. Hyperimmune serum was raised against the rHSPD1 in mice and immunohistochemistry was standardized to assess expression of this protein in various histotypes of canine mammary tumors. Elevated level of \textit{HSPD1} mRNA expression (4.92 ± 0.65folds) was observed in canine mammary tumors as compared to the healthy mammary tissue. Further, HSPD1 protein expression in 80% of healthy tissues showed mild immunoreactivity whereas, moderate to high expression of HSPD1 was seen in 80% CMT tissue samples.

Conclusions-

The findings suggest that HSPD1 could act as molecular marker for the diagnosis of mammary tumors in canines and also to assess the response to these subjects to treatment.

Introduction

The ubiquity of mammary tumor is seen in humans, dogs and cats but is infrequent in other species [1]. Canine mammary tumors are the most common neoplasia that are prominently seen in unsprayed female dogs [2]. There are a plethora of factors that contribute to the threat of developing the mammary tumors which include breed, age, ovariectomy, exogenous hormonal exposure, diet and obesity [3]. Conventionally, CMT is diagnosed by histopathological examination of the stained tumor sections. However, differentially expressed biomarkers can also be used for more specific diagnosis. Hence, identification and characterization of CMT specific/associated biomarkers is greatly encouraged for specific diagnosis of this malady [4].

Heat shock proteins (HSP) are highly conserved proteins that serve as mediators of hyperthermia resistance [5, 6, 7]. These proteins act as molecular chaperones that help in correct folding of the nascent polypeptide chains, translocation of proteins across the membranes, and marking the denatured ones for
degradation [8, 9]. Apart from the canonical functions, HSP also play an important role in carcinogenesis, immune response and apoptosis [6, 10].

In animal cells, the 60KDa HSPD1, also known as HSP60, primarily resides in the mitochondria whereas in plants they are located in the chloroplast. However certain studies have elucidated that HSPD1 is also located in the cytosol, cell surface, extra cellular space and biological fluids [11, 12]. In human beings, the HSPD1 gene is situated on chromosome 2q33.1 [13]. It is abundantly expressed in normal cells but its expression is further induced by stress factors [14, 15].

Higher HSPD1 mRNA and protein levels have been significantly associated with breast carcinogenesis in human beings and auto-antibodies against this chaperone have been found to be useful for the early diagnosis of breast cancer [16–19]. Elevated HSPD1 expression is also observed in astrogliaoma cells [20], colorectal cancer [21], cervical cancer [22], ovarian cancer [23] and prostate cancer [24]. Moreover, HSPD1 over-expression has also been reported in cellular infiltrate of canine mixed mammary carcinoma [25]. Scanty reports are available on the expression of HSPD1 in various other histotypes of CMT. Hence, we undertook this study to compare the HSPD1 mRNA and protein expression in different histotypes of CMT.

**Methods**

**Sample sources**

CMT samples (n=20) were collected from 6-12 years old dogs with a median of 8.5 years, during surgeries executed in the Department of Veterinary Surgery and Radiology, GADVASU, Ludhiana, India. Healthy canine mammary tissues were also collected from age and breed matched dogs (n=20). For the extraction of total RNA, tissue samples were collected in RNAlater™ and stored at -20°C. For histopathological and immunohistochemical analyses, tissue samples were collected in 10% Neutral Buffered formalin. The Institutional Animal Ethics Committee (IAEC), GADVASU approved the collection of tissue samples and experimentation on mice via memo no. GADVASU/2020/IAEC/53/14; dated 25/01/2020. Moreover, approval from the Institutional Biosafety Committee (IBSC) was also procured via memo no. IBSC/20/9 dated 14/01/2020 for recombinant DNA technology work.

**Histopathology**

Tissue samples collected in 10%NBF were processed and stained with Hematoxylin and Eosin (H&E). Classification and grading of the tumors were carried out according to WHO standards of classification and grading [26, 27].

**RNA isolation and cDNA synthesis**

Total RNA was extracted using TRIZol™ reagent (Life Technologies, USA) following the manufacturer’s protocol. Genomic DNA contamination (if any) was removed using DNase1. About 1µg of the isolated RNA was used for c-DNA synthesis using oligo dT primers and Bio-Rad iScript c-DNA synthesis kit (Bio-
Rad Laboratories, USA). Further the synthesized c-DNA was confirmed using specific GAPDH primers (Figure not shown here).

**Real Time PCR (qRT-PCR)**

Relative expression of *HSPD1* mRNA in tumorous and healthy canine mammary tissues was assessed by SYBR green based qRT-PCR. The specific primers targeting *HSPD1* gene (CGGGAACTAGCCTAAGCC and GTTCTTCCCTTGGCCCAT), along with endogenous housekeeping control genes, *RPS-19* (CCTTCCTCAAAAAAGTCTGGG and GTTCTCATCGTAGGAGCAAG) [28] and *β-actin* (CCGGAGAGATGACCAGA and GTGAGGATCTTCATGAGGTAGCG) [29] and iTaq universal SYBR® green supermix (BioRad, USA) were used for the expression profiling. The validity of these housekeeping genes had been previously checked in cancer studies [6]. Primers of all the three genes were used at 0.25µM final concentration. Annealing and extension of all the three genes were carried out at 60°C and dissociation curves were generated between 65°C to 95°C to assess the specificity of the amplicons.

The percent efficiencies of the PCR amplification for each gene was calculated as, $E = \left(10^{-1/slope} - 1\right) \times 100$, where slope was calculated for the semi-log regression curve plotted between log c-DNA (serially diluted cDNA samples) versus their threshold cycle (Ct) values [30]. For evaluating the fold change in *HSPD1* mRNA expression between canine mammary tumor and healthy mammary tissues, the Ct values of *HSPD1* gene and the geometric mean of the Ct values of *RPS-19* and *β-actin* after 40 cycles of amplification were utilized [31]. The statistical analyses were made according to Livak and Schmittgen (2001) [32] using SAS version 9.3. Further, qPCR score ($2^{-δCt}$) was also calculated for each sample to analyze the relationship between HSPD1 expression at mRNA and protein level.

**Cloning and sequencing of the canine HSPD1 gene**

Using the primer pick program of NCBI, primers AAC CAT GGA TAT GCT TCG ATT ACC CGC AGT (forward) AAC TCG AGA ACG TGG TTA ACA GAG AGG CCA (reverse) were designed to amplify the gene encoding *HSPD1* (Spanning 1643 bp). Further, to proceed with directional cloning, the sites for *Ncol* and *Xhol* restriction enzymes were added at the 5’ ends of both the primers. The primers were custom synthesized from Integrated DNA Technologies (IDT). Herculase II fusion DNA polymerase kit (Agilent, USA) was used to amplify the *HSPD1* gene as per the manufacturer’s instructions. 0.8 µM of each primer was used in 25µl reaction, which annealed with the template at 56°C. The product thus obtained was resolved on agarose gel (1.5%) and was purified using Quick gel extraction and PCR purification kit (Thermo Fisher Scientific, USA) following user’s guide.

Restriction enzyme double digestion (REDD) reaction was individually initiated for purified PCR product and circular pPROEX-HTa expression vector using *Xhol and Ncol* (New England Biolabs, UK) restriction enzymes. Both the digested vector and insert were ligated using T4 DNA ligase at 22°C and the ligated product was transformed into competent BL21DE3 cells and plated onto LB agar plates containing ampicillin (100µg/ml). Following 16 hours incubation, off-white colonies containing the recombinant plasmids were collected and allowed to grow in LB broth supplemented with the ampicillin (100µg/ml).
Subsequently, plasmids were isolated by alkaline lysis method [33] and restriction double digestion was performed to confirm the accurate orientation of insert into the vector using Ncol and Xhol (New England Bio labs, UK) restriction enzymes. Stabs containing the positive clones were forwarded to University of Delhi, South Campus (UDSC), New Delhi for custom sequencing. The deduced sequence was then deposited to NCBI & accession number was obtained.

**Heterologous expression of the recombinant HSPD1 (rHSPD1) and its purification**

A positive clone was cultured in bulk and subjected for IPTG induction (1mM) and pelleted down after 6 hours of induction. Purification of recombinant protein was performed under denaturing conditions as per standardized lab protocol [6]. Further, purified HSPD1 recombinant protein was dialyzed in Snake Skin Dialysis tubing, 10K MWCO (Thermo-Scientific, USA) for the removal of any residual urea and other undesired contaminant proteins. Expression of rHSPD1 was assessed by SDS-PAGE [34] and to confirm the expressed recombinant HSPD1 protein, western blotting [35] was carried using commercially available anti-HSPD1 antibody.

**Raising hyperimmune sera against canine rHSPD1 in mice**

To raise hyperimmune sera against rHSPD1, 10 Swiss Albino mice (4 months old) were used. Firstly mice were acclimatized for 1 week and later used for immunization. Purified recombinant HSPD1 protein was mixed with equivalent amount of Freund’s Complete Adjuvant (FCA) and was subcutaneously injected in mice (50µg protein/ mice) for the priming. Booster doses were injected on 7th, 14th, 21st and 28th day post priming with half the initial quantity of the protein emulsified in FIA. On 29th day, test bleeding was done from the tail veins of mice to examine the titer of antibodies [4]. The final bleeding was accomplished on 30th day by cardiac puncture and sera were collected. IgG purification kit (Thermo Scientific, USA) was used to purify immunoglobulin G from the harvested hyper immune sera. Western Blotting [39] was carried out using the purified IgG raised to detect HSPD1 in mammary tumor tissue homogenate.

**Immunohistochemistry (IHC) to analyze the tissue level expression of HSPD1**

IHC was carried out as per the protocol standardized in the lab [4]. Briefly, the tissue samples stored in 10%NBF were processed and paraffin wax blocks were prepared. Using rotary microtome 5µm thick sections of tissues were cut and mounted on slides coated with poly-L lysine. Slides were firstly deparaffinized by 2 changes of xylene and then rehydrated by immersing them in graded alcohols. Further, heat induced retrieval of epitope was done by dipping the slides in citrate buffer and heating in microwave for varied time and watts (3 minutes at 850W, 7 minutes at 450W). Slides were cooled down to room temperature and washed with 3 changes of PBST. Subsequently endogenous blocking was carried out by mixing 35µl of H₂O₂ in 1000ml of methanol and incubated in humidify chamber for 30 minutes. In order to minimize non-specific binding 2.5% Normal Horse Serum (Vector laboratories, USA)
was added and incubated for 40 minutes. After the completion of incubation period, primary antibody (purified IgG from hyperimmune serum) was poured in 1:250 dilution, and in the negative control unimmunized mice serum was added and slides were incubated at 4°C for overnight.

On the subsequent day, secondary HRP conjugate antibody (ImmPRESS Universal polymer kit, peroxidase, Vector Laboratories, USA) was poured and the slides were incubated at room temperature for 30 minutes in humidify chamber. Impact DAB substrate kit (Vector Laboratories, USA) was used for color development. Then slides were counterstained with Gill’s hematoxylin for 1 minute and were furthered dehydrated with graded alcohols and were finally mounted.

**Scoring of HSPD1 positive cells**

IHC analysis was carried out by applying semi-quantitative approach. In this method the intensity of developed brown color together with percentage of the cells showing positive staining were considered [4]. Scoring was carried out by a pathologist without considering the history of the patients [36]. To evaluate the H or SI score (staining index), the assigned score for the percentage of HSPD1 positive cells were multiplied with score provided for staining intensity. In order to detect the higher (SI>6) or lower (SI<6) HSPD1 expression at tissue level, SI score was used. Percentage of the positive cells were calculated by randomly allotted scores as- 1 for 0-25% positive cells, 2 for 26-50% positive cells, 3 for 51-75% positive cells and 4 for 76-100% positive cells. Staining intensity was scored as follows- no staining-0, mild staining- 1, moderate staining-2, intense staining- 3 respectively.

**Statistical Analysis**

Statistical analyses were performed with Statistical analysis software (SAS ver. 9.3). Pearson correlation coefficient (r) was calculated between H-score and $2^{-\delta Ct}$ (qRT-PCR score) in order to determine any association between them. Spearman's rank correlation was also calculated between the scores. Statistical association of tumor histotypes with tumor grades, qRT-PCR score and H score, was assessed using the Kruscal Wallis test.

**Results**

**Histopathological analysis of CMT**

Of the 20 tumor samples, 11 were classified as complex carcinoma, three were anaplastic carcinoma, two each were papillary carcinoma and mixed tumor respectively, one each were hemangiosarcoma and mast cell tumor. About 55% (n=11) were designated as grade II (moderately differentiated), 30% tumors (n=6) were found to be of grade I (well differentiated) and only 15% tumors (n=3) belonged to grade III (poorly differentiated).

**Expression analysis of HSPD1 mRNA using Real Time PCR**
In our study, HSPD1, RPS19 and β-actin genes had amplification efficiencies of 86.78%, 95.63%, and 96.44% respectively, suggesting that the exponential efficiencies of HSPD1 gene along with the internal controls were suitable for real time PCR. A significantly elevated expression of $4.92 \pm 0.65$ folds ($p<0.05$) for HSPD1 mRNA was observed in canine mammary tumors as compared with healthy tissue samples.

**Cloning, expression of HSPD1 gene and purification of recombinant HSPD1 protein**

A single specific band corresponding to 1643 bp was resolved upon the PCR amplification using specific primers targeting the HSPD1 gene (Fig. 1). The isolated plasmids from the cultured positive clones, upon NcoI and XhoI restriction enzyme double digestion released a specified insert of 1643bp (Fig. 2), which confirmed proper cloning of the gene. The obtained positive clones were forwarded for custom sequencing and the deduced sequence was deposited to GenBank of National Center for Biotechnology information (NCBI) with an accession no. OK484370.

Upon induction with 1mM IPTG, the expression kinetics revealed that after 6 hours post IPTG induction, expression level of rHSPD1 was optimum. Upon Ni-NTA based affinity chromatography, under denaturing conditions, the purified recombinant protein was resolved as a 60kDa protein on SDS-PAGE analysis (Fig. 3). The total yield of the rHSPD1 protein was 6.2 mg/L of the induced culture. A specified immunoreactivity corresponding to 60kDa on the nitrocellulose membrane post Western blotting confirmed the recombinant protein (Fig. 4).

The IgG purified from the hyperimmune sera also distinctly reacted with native HSPD1in the tumor tissue homogenate upon Western blotting (Fig. 5), which confirmed that the purified IgG specifically reacted with the native cellular HSPD1.

**Immunohistochemical detection of HSPD1 expression in canine mammary neoplasia**

The HSPD1 immunopositive cells were stained brown, which was restricted to the cytoplasm of the cells alone. The negative controls, in which unimmunized mice serum was used, didn't show any immunostaining with the raised HSPD1 antibodies. Immunoreactivity against cellular HSPD1 was judged based on the staining index (SI) obtained by multiplying the number of immunopositive cells in random fields with the staining intensity score of the pathologist. Tissue expression of HSPD1 was judged as strong when SI was greater than/equal to 6 and it was referred to as mild when SI was less than 6 [4]. Based on this convention, a mild expression of HSPD1 was detected in most (80%) of the healthy mammary glands (Fig. 6), while a varied HSPD1 expression was evident in most of the CMT histotypes under study. The immunoreactivity for HSPD1 was found to be strong in 80% of the CMT tissues (Fig. 7). Further, a weak HSPD1 expression was indicated in all the specimens of hemangiosarcoma and papillary carcinoma, while, a strong HSPD1 expression was seen rest of the histotypes of CMT under study (mixed mammary tumors, anaplastic carcinomas complex carcinomas and mast cell tumors). When, HSPD1 expression was compared with different grades of CMT, a strong HSPD1 expression was discerned in 50%, 72.73% and 85.57% of grade-1, grade-2 and grade-3 CMT respectively.
**Relationship between HSPD1 expression at mRNA and protein level in various types of CMT**

The statistical analysis between the IHC score and qRT-PCR score revealed that there was no significant correlation between HSPD1 transcript and protein expression. However, the Kruscal Wallis test revealed significant differences ($P<0.05$) in the H scores alone with respect to different CMT histotypes. The Wilcoxon mean rank for H score was highest in mixed mammary tumor and least in papillary carcinoma indicating that HSPD1 expression was least in papillary carcinoma and was highest in mixed mammary tumors among the CMT histotypes under study. Moreover, one way ANOVA was also carried out to check for the significant differences of HSPD1 expression (if any) in various histotypes of CMT based on the H scores. It was found that, the expression of the protein (H-score) in complex carcinoma (9.00±0.69), mixed mammary tumors (10.00±0.91) and mast cell tumors (8.00±1.29) were significantly higher ($P<0.05$) than that in papillary carcinoma (1.68±1.05).

**Discussion**

In this contemporary epoch, the incidence of canine mammary neoplasia, is raising day by day globally. But, with the advent of advanced technology, it is possible to diagnose a majority of these tumors at an early stage. For the diagnosis of CMT, the histopathological examination is valuable but involves an invasive tissue collection process and fine needle aspiration which is less invasive is less specific too. In this pursuit, the identification of certain biomarkers to diagnose this malady is absolutely crucial. The progressive research in the cancer biology has depicted the significance of HSP as potential biomarkers of carcinogenesis for certain human cancer types [6]. HSPD1 is a heat shock protein that also plays an indispensable role in immune responses has anti-apoptotic characteristics and promotes tumor growth, progression, invasion, and metastasis. It is also accountable for treatment resistance and worse survival rates. During carcinogenesis, HSPD1 is deposited on the outside of mitochondria, in the cytoplasm, plasma membrane, and secretory vesicles, protecting tumour cells from external environmental stress and promoting cell proliferation. HSPD1 also plays a role in the permeabilization of the mitochondrial membrane by interacting with cyclophilin D, a protein that regulates the permeability transition pore in mitochondria. HSPD1 controls the action of p53 and causes a cytoprotective cascade by stabilising the quantum of survivin. The mitochondrial survivin stores are depleted as a result of acute HSPD1 extraction. Survivin is known for inhibiting apoptosis, as well as increasing p53 expression and triggering p53-dependent apoptosis in tumour cells. These cytoprotective characteristics of HSPD1 have been thoroughly investigated in vivo in malignancies, where HSPD1 is selectively upregulated in contrast to normal cells, while HSPD1 deficiency in normal cells is not connected to mitochondrial malfunction or cell death.

Moreover, HSPD1 not only stabilises the amount of survivin in the mitochondria, but it also provides cytoprotection through another method, which involves the formation of a complex by HSPD1’s connection with p53, which inhibits the function of p53 tumor cells [37]. Several reports advocate that
HSPD1 is up-regulated in human breast cancer. Provided that, CMT and human breast cancer share a close association, we chose to study the expression of HSPD1 in canine mammary tumors.

In our study majority of the tumors were complex carcinomas. Many reports in the past also advocate that complex carcinomas, among all other canine mammary tumors are the most pervasive [6, 10, 25, 38, 39, 40, 41]. In our study, HSPD1 mRNA was 4.92 ± 0.65 folds overexpressed in CMT. In the past, Desmetz et al (2008) [16] reported an elevated expression of HSPD1 in early breast cancer. Apart from breast cancer, an increased HSPD1 mRNA expression has also been reported in ovarian [42] and colorectal cancer [43] in human beings. However, a down regulation of HSPD1 mRNA expression has also been reported in hepatocellular carcinoma [44].

In human breast pathology, IHC is routinely used in the diagnosis and prognosis of breast neoplasia. In the present study, we found a strong expression of HSPD1 in a majority of CMT tissues. In the past, a moderate to high cytoplasmic expression of HSPD1 has been reported in cellular infiltrate of mixed canine mammary carcinomas [25] and triple negative human breast cancer [45] which was associated with an advanced stage of tumor. It has also been reported that the elevated expression of HSPD1 in initial stages of breast carcinogenesis has a significant correlation with tumor growth and progression [16]. In our study, we found a strong HSPD1 expression in a majority of CMT histotypes. Hence, adding HSPD1 to the current panel of CMT biomarkers will certainly improve the sensitivity and specificity of CMT diagnosis.

**Conclusion**

We report an elevated level of HSPD1 expression in various histotypes of canine mammary tumors. HSPD1 protein expression was maximum in mixed mammary tumors whereas in the papillary carcinoma the expression was minimum. However, due to the smaller sample size, the data need to be confirmed in a study employing a large number and types of CMT in future.

Figures
Figure 1

Amplicon of *HSPD1* gene (Lane 1: 1kb plus DNA ladder; Lane 2: ~1643bp *HSPD1*amplicon; Lane 3: non template control (NTC)
Figure 2

Restriction enzyme double digestion of pPROEXHTa- HSPD1 plasmid (Lane 1: undigested plasmid; Lane 2: 1 kb plus DNA ladder; Lanes 3-6: NcoI and XhoI digested plasmid)
Figure 3

SDS PAGE depicting purified recombinant HSPD1 protein (Lane M: Pre-stained protein ladder; Lane 1-3: purified protein)
Figure 4

Western blotting analysis of recombinant HSPD1 protein (Lane M: Pre-stained protein ladder; Lane 1: Immuno reactive rHSPD1)
Figure 5

Western Blot analysis of rHSPD1 protein by using IgG purified from hyperimmune sera raised against rHSPD1 in mice (Lane M: Pre-stained protein ladder; Lane 1: Immuno reactive rHSPD1)
Figure 6

Immunolocalization of HSPD1 showing mild expression of HSPD1 within the cytoplasm in healthy tissue (IHC, 20μm).
Figure 7

(a) Anaplastic carcinoma: Immunolocalisation of HSPD1 showing intense expression of HSPD1 within the cytoplasm and mostly perinuclear area of the neoplastic epithelial cells (IHC, 20\(\mu\)m); (b) Hemangiosarcoma: Immunolocalisation of HSPD1 showing mild expression of HSPD1 in the cytoplasm of the neoplastic epithelial cells (IHC, 20\(\mu\)m); (c) Papillary Carcinoma: Immunolocalisation of HSPD1 showing mild expression of HSPD1 in the cytoplasm of the neoplastic epithelial cells (IHC, 20\(\mu\)m); (d) Complex Carcinoma: Immunolocalisation of HSPD1 showing intense expression of HSPD1 in the cytoplasm of the neoplastic epithelial cells which are arranged in nest (IHC, 20\(\mu\)m); (e) Mixed mammary tumor: Immunolocalisation of HSPD1 showing moderate expression of HSPD1 in the cytoplasm of the epithelial cells and fibroblast (IHC, 20\(\mu\)m); (f) Mixed mammary tumor: Immunolocalisation of HSPD1 showing moderate expression of HSPD1 in the cytoplasm of the epithelial cells and fibroblast (IHC, 20\(\mu\)m).
