1. Introduction

The problems of hydromagnetic free convection flow of incompressible fluids over corrugated vibrating surface have drawn considerable attention from several medical researchers and engineers, resulting in the enhanced heat transfer performance by increasing the area over which heat transfer takes place. This technology is applied in the design of processing equipment that complies with cheap, environmental friendly, and energy-saving with high efficiency of mass and heat transfers. Temperature control is important in corrugated structures manufacturing because it helps to ensure a strong bond between the layers of the corrugated surface and indicates moisture content [1].

Fluid flow and heat transfer on corrugated channel laminar in nature were first studied by [2] for transitional and low Reynolds number turbulent flow. Magnetohydrodynamic free convection flow past an infinite vertical plate oscillating in its plane was studied in the case of an isothermal plate [3]. Rizwan et al. [4] investigated MHD natural convection flow enclosure in a corrugated cavity filled with a porous medium with a complete structure of corrugated surface for heat transfer effects in the presence of the uniform magnetic field. The unsteady flow of second-order thermoviscous incompressible forced oscillations of a fluid bounded by rigid bottom was studied by [5]. Also, Schlichting [6] observed experimentally and numerically that corrugated channels do not have significant effects on heat transfer enhancement if operated in a steady regime. Garg and Maji [7] numerically studied the heat transfer of sinusoidal wavy channels at zero degrees phase shift. A numerical analysis of laminar forced convection in corrugated-plate channels with a sinusoidal, ellipse, and rounded-vee wall shapes were studied [8]. Furthermore, Gbadeyan et al. [9] investigated Soret and Dufour effects on heat and mass transfer in chemically reacting MHD flow through a wavy channel using amplitude as the perturbation parameter.

This work attempts to study the effects of velocities, concentration, and temperature fields on the unsteady flow of incompressible fluid over the heated oscillating bottom for the various material parameters.
2. Mathematical Formulation

Consider a two-dimensional unsteady flow of a viscous incompressible fluid that is electrically conducting flows upwards on an oscillating bottom surface. The x-axis is taken along the infinite surface and the y-axis normal to it. The corrugated surface and the fluid are initially put at the same temperature. The fluid is initially at rest, responds to the fluctuations of the bottom and the periods of oscillation of the fluid response, and the temperature distribution are assumed to be oscillatory with the same frequency. At time $t > 0$, the plate starts vibrating with a frequency of oscillation $\omega$ and reference velocity $U_x$ forming boundary oscillating velocity $u = U_x \sin \omega t$ approximated [10]. A magnetic field $B_0$ of uniform strength is applied perpendicular to the plate along the positive z-axis and the magnetic Reynolds number is assumed to be small since the electric intensity $E$ is zero at the plate; therefore, it is assumed to be zero everywhere within the flow [11–13]. The bottom surface is subjected to perturbations through forced transverse oscillations. Linear sinusoidal displacement of the fluid along the vibrating surface, along the x-axis, is generated. Under the Navier–Stokes equation approximation, the viscous stress tensor is zero. The restoring force that produces the oscillation is the buoyancy force, and the waves are associated with these vibrations. The boundary contains the effect of confining the wave energy to a region of finite extent. Corrugation causes periodic variation in the force component and the oscillations due to vortex shedding [14]. Fluid damping is generated as a result of relative fluid movement to the vibrating structure [15]. It means that the cross-flow vibration is caused by the lift force while the inline flow vibration is caused by the drag force, which in all cases are vortex-induced vibrations represented by periodic corrugation [2]. From Lorentz force, a moving particle with velocity, carrying a charge, contains a force acting on this particle. Also, the magnetic field vector $B$ is perpendicular to the vibrating surface.

A current is induced in a conducting loop when magnetic flux linking the loop changes [16, 17]. The electric field intensity in a region of time with varying magnetic flux density is present. When the magnetic Reynolds number is small [3, 18] the induced magnetic field is negligible in comparison with the applied magnetic field, therefore becoming constant. Since the corrugated bottom surface is nonconducting, therefore the heat flux is zero at the surface and hence zero everywhere in the flow. There is a variation in the temperature and the density, but density is neglected everywhere [19, 20] apart from the buoyancy terms which varies linearly with the local temperature and mass fraction.

Under the above-stated conditions and assuming variation of density in the body force term under Boussinesq’s approximation [7], the problem is governed by the following momentum equations describing velocity profiles:

$$\frac{\partial u}{\partial t} + u \frac{\partial u}{\partial x} + v \frac{\partial u}{\partial y} = \nu \left( \frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} \right) + g \beta_T (T - T_\infty) + g \beta_C (C - C_\infty) - \frac{\sigma u B_0^2}{\rho},$$  \hspace{1cm} (1)

$$\frac{\partial v}{\partial t} + u \frac{\partial v}{\partial x} + v \frac{\partial v}{\partial y} = \nu \left( \frac{\partial^2 v}{\partial x^2} + \frac{\partial^2 v}{\partial y^2} \right) - \sigma v B_0^2,$$  \hspace{1cm} (2)

$$\frac{\partial C}{\partial t} = D_M \left( \frac{\partial^2 C}{\partial x^2} + \frac{\partial^2 C}{\partial y^2} \right) + D_l k_f \left( \frac{\partial^2 T}{\partial x^2} + \frac{\partial^2 T}{\partial y^2} \right) - u \frac{\partial C}{\partial x} - v \frac{\partial C}{\partial y},$$  \hspace{1cm} (3)

$$\frac{\partial T}{\partial t} + u \frac{\partial T}{\partial x} + v \frac{\partial T}{\partial y} = \frac{\kappa}{\rho C_p} \left( \frac{\partial^2 T}{\partial x^2} + \frac{\partial^2 T}{\partial y^2} \right) + \mu \left[ \frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} \right]^2 + \frac{D_M k_f}{C_p C_s} \frac{\partial C}{\partial x} \left( \frac{\partial C}{\partial x} + \frac{\partial C}{\partial y} \right) + \frac{\sigma B_0^2}{\rho C_p} (u'^2 + v'^2) + \frac{\partial q_r}{\partial z}.$$  \hspace{1cm} (4)

The heat due to viscous dissipation is taken into an account and thermal radiation is assumed to be present in the form of a unidirectional flux in the z-direction denoted by $q_r$. By using the Rosseland approximation [19], the radiative heat flux $q_r$ is given by

$$q_r = \frac{4 \sigma \, T^4}{3 k_c}.$$  \hspace{1cm} (5)

Since temperature differences within the flow are sufficiently small, then (5) can be linearized by expanding $T^4$ in Taylor series about $T_\infty$, which after neglecting higher-order terms is

$$T^4 \equiv 4 T^3 T_\infty^3 - 3 T^4_\infty.$$  \hspace{1cm} (6)

Substituting the partial derivative with respect to $T$ of (5) in (4), the rate of change of radiative heat becomes

$$\frac{\partial T}{\partial t} + u \frac{\partial T}{\partial x} + v \frac{\partial T}{\partial y} = \frac{\kappa}{\rho C_p} \left( \frac{\partial^2 T}{\partial x^2} + \frac{\partial^2 T}{\partial y^2} \right) + \mu \left[ \frac{\partial u}{\partial x} \right]^2 + \frac{D_M k_f}{C_p C_s} \frac{\partial C}{\partial x} \left( \frac{\partial C}{\partial x} + \frac{\partial C}{\partial y} \right) + \frac{\sigma B_0^2}{\rho C_p} (u'^2 + v'^2) - \frac{16 \sigma T^3_\infty}{3 k_c} \frac{\partial^2 T}{\partial y^2}.$$  \hspace{1cm} (7)
With initial and boundary conditions,
\[ t = 0 : u = 0, v = 0, T = 0, C = 0 \text{ at } 0 \leq x \leq L, \]
\[ t > 0: U = U_{co}, C = C_{w}, T = T_{w}, C = C_{co} \text{ at } x = 0, \]
\[ u = U_{r} \sin \omega t, \]
\[ T = T_{co} + (T_{w} - T_{co}), \]
\[ \nu = 0, \]
\[ C = C_{co} + (C_{w} - C_{co}) \text{ at } y = 0. \]

Introducing nondimensional numbers,
\[ x = Lx^{*}, \]
\[ y = Ly^{*}, \]
\[ u = U_{r} \sin \omega t, \]
\[ v = U_{r}v^{*}, \]
\[ t = t^{*} \frac{t_{r}}{L}, \]
\[ \nu = U_{r} \sin \omega t, \]
\[ v = U_{r}v^{*}, \]
\[ \frac{1}{\tau} = \frac{t^{*}}{t_{r}}, \]
\[ \frac{v}{\nu} = U_{r}v^{*}, \]
\[ \frac{T^{*}}{T_{w} - T_{co}} = T^{*} = T_{co} + (T_{w} - T_{co}), \]
\[ \frac{C^{*}}{C_{co} - C_{w}} = C^{*} = \frac{C_{co} - C_{w}}{C_{co} - C_{co}}, \]
\[ \frac{\Delta T}{T_{w} - T_{co}} = \Delta T^{*} = T_{w} - T_{co}, \]
\[ \frac{U_{r}}{(\nu g \beta \Delta T)^{1/3}} = U_{r} = \frac{U_{r}L}{\nu}, \]
\[ \frac{\Delta T^{*}}{T_{w} - T_{co}} = \Delta T^{*} = T_{w} - T_{co}. \]

Equations (1)–(3) and (6) are nondimensionalised as follows.

Momentum equations in \(x\)-axis and \(y\)-axis are given as
\[
\frac{\partial u^{*}}{\partial t^{*}} + u^{*} \frac{\partial u^{*}}{\partial x^{*}} + v^{*} \frac{\partial u^{*}}{\partial y^{*}} = \frac{1}{\text{Re}} \left( \frac{\partial^2 u^{*}}{\partial x^{*2}} + \frac{\partial^2 u^{*}}{\partial y^{*2}} \right) + \text{Gr}_{m} \Delta T^{*} - \text{Mu}^{*} + \text{Gr}_{m} \Delta T^{*} - \text{Mu}^{*},
\]
\[ \frac{\partial v^{*}}{\partial t^{*}} + u^{*} \frac{\partial v^{*}}{\partial x^{*}} + v^{*} \frac{\partial v^{*}}{\partial y^{*}} = \frac{1}{\text{Re}} \left( \frac{\partial^2 v^{*}}{\partial x^{*2}} + \frac{\partial^2 v^{*}}{\partial y^{*2}} \right) - \text{Mu}^{*}. \]

The energy equation is given as
\[
\frac{\partial T^{*}}{\partial t^{*}} + u^{*} \frac{\partial T^{*}}{\partial x^{*}} + v^{*} \frac{\partial T^{*}}{\partial y^{*}} = \frac{1}{\text{Pr}} \left( \frac{\partial^2 T^{*}}{\partial x^{*2}} + \frac{\partial^2 T^{*}}{\partial y^{*2}} \right) + \text{Ec} \left( \frac{\partial u^{*}}{\partial x^{*}} + \frac{\partial v^{*}}{\partial y^{*}} \right)^2 \]
\[ + D_{f} \text{Re} \left( \frac{\partial^2 C^{*}}{\partial x^{*2}} + \frac{\partial^2 C^{*}}{\partial y^{*2}} \right) \]
\[ + \Delta T \text{Re} \left( \frac{\partial^2 T^{*}}{\partial x^{*2}} + \frac{\partial^2 T^{*}}{\partial y^{*2}} \right). \]
With the following initial and boundary conditions,

\[ t^* = 0: \quad u^* = 0, \quad v^* = 0, \quad T^* = 0, \quad C^* = 0 \quad \text{at} \quad 0 \leq x^* \leq L, \]

\[ t^* = 0: \quad u^* = \sin \omega t, \quad v^* = 0, \quad T^* = 1, \quad C^* = 1 \quad \text{at} \quad x^* = 0, \]

\[ u^* = 0, \quad v^* = 0, \quad T^* = T_\infty + (T_w - T_\infty), \quad C^* = C_\infty + (C_w - C_\infty) \quad \text{at} \quad y^* = 0, \]

\[ u^* = 0, \quad v^* = 0, \quad T^* = 1, \quad C^* = 1 \quad \text{at} \quad x^* = L. \]

(15)

The Skin friction, Nusselt number, and Sherwood number at the corrugated surfaces are estimated as follows:

\[ C_f = \left( \frac{\partial u}{\partial x} \right)_{x=0}, \]

\[ \text{Nu}_x = \left( \frac{\partial T}{\partial x} \right)_{x=0}, \quad (16) \]

\[ \text{Sh} = \left( \frac{\partial C}{\partial x} \right)_{x=0}. \]

### 3. Numerical Technique

The partial differential equations (10)–(14) show the solutions to highly nonlinear coupled governing equations of velocity, concentration, and temperature with the various physical parameters, and the associated boundary conditions in (15) are solved numerically using the explicit finite difference method of the Forward Time Backward Space (FTBS) scheme since this method is stable and is validated using computer software. This is carried out by discretizing the computational domain with nonuniform grids of sinusoidal elements. The flow is in two dimensions and therefore flow domain is confined by the \( x, y \), and \( t \) axes. The approximate values of \( u^* \), \( v^* \), \( C^* \), and \( T^* \) are found at every nodal point for particular \( i \) at \((k+1)\)th time level. A necessary condition for time stability, the Courant–Friedrichs–Lewy (CFL) condition, which depends on time and space discretization, is used. The FTBS finite difference method is applied to replace continuous derivatives with difference formulas that involve only the discrete values associated with positions on the mesh. The basic unknowns for the above differential equations are the velocity components \( U_{k,j}^m, V_{k,j}^m \), the temperature \( T_{k,j}^m \), and the concentration \( C_{k,j}^m \).

Momentum equations expressed in finite differences is given as

\[
U_{k,j}^{m+1} = \left( \left[ U_{k,j}^m - (\Delta t/2\Delta x)U_{k+1,j}^m - U_{k-1,j}^m + (\Delta t/2\Delta x)^2 \right] \left[ 2U_{k+1,j}^m + U_{k,j}^m - 2U_{k-1,j}^m \right] + \left[ (\Delta t/2\Delta x)^2 \right] \left[ (U_{k+1,j}^m + U_{k,j}^m + U_{k-1,j}^m) \right] - M(\Delta t/2)U_{k,j}^m \right) - \left[ (1 + U_{k,j}^m)(\Delta t/2\Delta x) + (\Delta t/\text{Re}(\Delta x)^2) + (\Delta t/\text{Re}(\Delta y)^2) + M\Delta t \right]^{-1},
\]

\[
V_{k,j}^{m+1} = \left( \left[ V_{k,j}^m - (\Delta t/2\Delta y)V_{k+1,j}^m - V_{k-1,j}^m + (\Delta t/2\Delta y)^2 \right] \left[ 2V_{k+1,j}^m + V_{k,j}^m - 2V_{k-1,j}^m \right] + \left[ (\Delta t/2\Delta y)^2 \right] \left[ (V_{k+1,j}^m + V_{k,j}^m + V_{k-1,j}^m) \right] - M(\Delta t/2)V_{k,j}^m \right) - \left[ (1 + V_{k,j}^m)(\Delta t/2\Delta y) + (\Delta t/\text{Re}(\Delta x)^2) + (\Delta t/\text{Re}(\Delta y)^2) + M\Delta t \right]^{-1}.
\]

The concentration equation expressed in finite differences is given as

\[
C_{k,j}^{m+1} = \left( \left[ C_{k,j}^m - (\Delta t/2\Delta x)C_{k+1,j}^m - C_{k-1,j}^m \right] + \left[ (\Delta t/2\Delta x)^2 \right] \left[ (C_{k+1,j}^m + C_{k,j}^m + C_{k-1,j}^m - 2C_{k,j}^m) \right] - M(\Delta t/2)C_{k,j}^m \right) - \left[ (1 + (\Delta t/2\Delta x)T_{k,j}^m + (\Delta t/\text{ReSc(\Delta x)^2}) + (\Delta t/\text{ReSc(\Delta y)^2}) + M\Delta t \right]^{-1}.
\]

\[(19)\]
4. Discussion of the Results

The effects of various parameters on the flow field of the physical problem for velocities, concentration, and temperature are discussed based on the following considerations:

(i) The value of Prandtl number Pr is taken to be to 0.71 corresponding to air
(ii) The value of Schmidt number Sc is chosen 0.22 which represents hydrogen at approx. \( T_m = 25^\circ C \) and 1 atm
(iii) The values of Dufour number Df and Soret number Sr are chosen in such a way that their product is constant provided that the mean temperature \( T_m \) is kept constant as well
(iv) The radiation parameter \( N \) is kept constant at \( N = 3 \) as an indication that there is strong thermal radiation compared with thermal conduction

4.1. Velocity Profiles. The analytical solutions to the coupled equations (10)–(14) together with the boundary condition (15) yield the velocity distribution. Figures 1–10 show the variations of velocity profiles with different values of different parameters. The graphs shown the figures are generated using MATLAB Code, for instance, by fixing the values of \( Gr_\beta = 10 \), \( Gr_m = 10 \), \( M = 0.2 \), \( Ec = 0.5 \), \( Df = 0.03 \), \( Sr = 0.08 \), \( Sc = 0.22 \), \( R = 0.2 \), and \( \omega t = \pi / 6 \) and varying the value Pr.

As shown in Figure 1, the magnitude of the Prandtl number, \( Pr \), is varied in Table 1, that determines whether the thermal boundary layer is larger for \( Pr \leq 1 \), where buoyancy forces are in balance with the thin viscous boundary layer, or smaller for \( Pr \geq 1 \), where inertial and buoyancy forces are in balance with the momentum boundary layer; this is shown at the oscillating bottom surface with the wave-like motion. A smaller value of \( Pr \) is an indication that heat diffuses faster than velocity; therefore, it is clear that fluids with small Prandtl numbers are free-flowing liquids with high thermal conductivity and are therefore a good choice for heat-conducting liquids, as shown in Figure 1.

Figure 2 shows the effect of Reynolds number on secondary velocity profiles. Since Re is associated with the smoothness of fluid flow, at lower velocities the flow is laminar and this is pictured as a series of parallel layers moving at different velocities. In the presence of oscillations, the fluid flows vigorously and reaches a velocity at which the velocity changes from laminar to turbulence. When a small Re is used, it applies that the viscous force is predominant thus imposing drug in the fluid and reducing the fluid flow.

The effect of local mass Grashof number \( Gr_m \) on velocity is shown in Figure 3. In this case, mass transfer natural convection is as a result of concentration gradients rather than temperature gradients. It is clear that when the value of \( Gr_m \) increases, the velocity rises as it reaches the greatest value near the surface due to the enhancement in the buoyancy force (Tables 1–3).

The inline vibration of a structure is caused by the oscillating drag force with different ranges in the reduced velocities. A similar effect is experienced when thermal Grashof number \( Gr_\beta \) is used, as shown in Figure 4. By varying the values of \( Gr_\beta \), the effects of free convection currents on the flow are indicated and the fluid’s velocity increases since fluid flow is aided by the free convection currents.

Figure 4 shows that when the values of \( Gr_\beta \) causes a rise in velocity profiles on a cooled surface due to the varying nature of boundary conditions, an indication that the thermal radiation parameter produces significant increases in the thermal conditions of the fluid temperature which consequently induces more fluid in the boundary layer through buoyancy effect to the viscous force, therefore enhancing fluid velocity. Variation in \( Gr_\beta \) and \( Gr_m \), as shown in Figure 5, has an increasing effect on velocity near the
center as a result of thermal and mass buoyancy forces due to cooling of the surface, by making the bond between the fluids to become weaker, strengthening the internal friction to reduce, and the gravity becoming stronger enough. Due to oscillation, thermal and flow patterns adjacent to the boundary are mainly affected.

A reverse effect in the case of heating of the surface, where $Gr_m < 0$ and $Gr \theta < 0$, is shown in Figure 6. Reducing the effect on velocity near the center as a result of thermal and mass buoyancy forces due to the heating of the surface is carried out by making the bond between the fluids to become stronger thus strengthening the internal friction to increase and the gravity becoming weaker enough.

It is observed from Figure 7 that while all other participating parameters are held constant, the values of $Sc$ from
hydrogen to atmosphere pressure reduce the velocity due to oscillation. Since Sc is the ratio velocity boundary layer to the concentration boundary layer which is comparable to Prandtl number in heat transfer, therefore Sc is applied to characterize flows when there are simultaneous momentum and mass transfer.

Figure 8 depicts the effects of velocity on the magnetic parameter $M$. Velocity rises as values of $M$ improves because the frictional or drag force (Lorentz force) in the magnetic field is responsible, which affects the velocity field that opposes the fluid motion, causing the velocity to decrease.

An increase in magnetism significantly reduces the thickness of the boundary layer, thereby reducing the velocity components. A reversal in the direction of the secondary velocity profiles is achieved by using large values of $M$. Here, the effective conductivity of the fluid rises with a rise in $M$ as a result of damping force due to oscillation.

The Soret effect causes the main-flow shear stress to rise and the cross-flow shear stress to fall, as shown in Figure 9. By decreasing the values of Sr effect leads to a rise in the main flow and cross-flow velocities, as an indication that the velocity boundary layer thickness decreases with an increase in Sr as a result of mass buoyancy force. This brings about the thermal diffusion effect.

Figure 10 shows that when the values of the Dufour number increases, velocity rises as an indication that the velocity boundary layer thickness increases due to mass diffusion effect.

4.2. Concentration Profiles. Prandtl number shows how fast thermal diffusion takes place in comparison to momentum diffusion. Here, the values of Prandtl number Pr used are Pr = 0.16 representing a mixture of noble gases, Pr = 0.63 for oxygen, Pr = 0.71 for air, Pr = 1.38 for gaseous ammonia,
and Pr = 7.56 for water at 20°C and one-atmosphere pressure. It is clear from Figure 11 that an increase in Pr causes a fall in concentration due to the Brownian motion of the fluid as a result of an increase in migration from the high concentration regions to the regions with low concentration.

The Reynolds number used is assumed to be small so that the induced magnetic field is neglected within the fluid particles as the fluid moves due to vibration, as shown in Figure 12. It is clear that the Reynolds number is varied in Table 2, to help predict flow patterns in different fluid flow situations.

As the values of Schmidt number rises, i.e., 0.22 (hydrogen), 0.62 (water vapour), and 0.78 (ammonia), from Figure 13, the concentration profile rises because the concentration profile and the boundary layer thickness decreases, corresponding to a thinner concentration boundary layer relative to the momentum boundary layer.

The effect of oscillation on velocity is overcome by freestream velocity, leading to the observed crossover of concentration profiles. When the values of Dufour number increases, the fluid concentration field reduces the boundary layer thickness due to oscillation, as shown in Figure 14.

4.3. Temperature Profiles. An increase in Prandtl number results in a fall in temperature, as shown in Figure 15, because the thermal boundary layer thickness decreases with increasing Pr. This is because the fluid viscosity becomes larger and reduces the thickness of the thermal boundary layer. In cases where Pr is high in liquids, the instability is hydrothermal and the related mechanism involves communication between free-surface temperature perturbations and bulk-liquid temperature. By eliminating the free-surface temperature, oscillations caused by hydrothermal wave coupling could be broken and they would cease. A smaller value of Pr is an indication that heat diffuses quickly compared to the velocity.

Reynolds number incorporates the physical properties of liquid density and dynamic viscosity which are directly related to temperature. This means that dynamic viscosity decreases in response to falling density. From Figure 16, as the temperature rises, the change in viscosity decreases due to the presence of the inertia force. Reynolds number is directly proportional to the temperature.

The Eckert number influences the self-heating of a fluid due to dissipation as a result of internal friction of the fluid. If dissipation is neglected at Ec ≤ 1 as shown in Table 3. Using Figure 17, it is shown that for higher values of the Eckert number Ec, the rate of heat transfer decreases. All the terms in the energy equation describing the effects viscous dissipation and body forces on the energy balance can be neglected, and the equation reduces to a balance between conduction and convection. The effect of viscous dissipation on the flow field is to increase
the energy, resulting in greater fluid temperature and as a consequence greater buoyancy force. The increase in the buoyancy force due to an increase in the dissipation parameter enhances the temperature.

Figure 18 shows that the Dufour number is directly proportional to the fluid temperature when other parameters are kept constant as a result of thermal boundary layer thickness.

The values of skin friction, Nusselt number, and Sherwood number are computed from random values generated from MATLAB, as shown in Table 4.
From Table 4, as time increases, the Nusselt number, Sherwood number, and Skin friction decrease, as it physically implies that shear stresses decrease with an increase in time. A higher value of radiation parameter leads to an increase in magnitudes of skin frictions and Nusseltnumber as a result of an increase in the rate of species concentration. The effect of radiation is to decrease the rate of energy transport to the fluid, thereby decreasing the temperature of the fluid, but it decreases in Sherwood number.

5. Conclusion

A numerical study has been conducted on free convective heat and mass transfer of an incompressible electrically...
conducting fluid on a vibrating bottom surface. Comparing from various pieces of literature, it is clear that

(i) Concentration is directly proportional to Reynolds number and inversely proportional to the Prandtl, Schmidt, Dufour, and Soret numbers, respectively.
(ii) Temperature profiles are directly proportional to the Reynolds, Eckert, and Dufour numbers, respectively, and inversely proportional to the Prandtl number.
(iii) The velocity profiles are directly proportional to Re, Gr_g, and Gr_m and inversely proportional to M.
(iv) Fluid damping is generated as the bottom surface vibrates normal to the flow, and this is proportional to the surface velocity. Therefore, an increase in damping causes an increase in velocity. Therefore, corrugated bottom surface is effective on heat transfer enhancement by breaking and destabilizing the thermal boundary layer.

Nomenclature

| Symbol | Description |
|--------|-------------|
| B_o    | Magnetic field strength (Wbm^{-1}) |
| B      | Magnetic flux density (Wbm^{-2}) |
| Sc     | Schmidt number |
| Sr     | Soret number |
| Df     | Dufour number |
| D_M    | Molecular diffusion coefficient (m^2s^{-1}) |
| M      | Magnetic parameter |
| T      | Dimensional temperature of the fluid (K) |
| N      | Radiative parameter |
| g      | Acceleration due to gravity (ms^{-2}) |
| Pr     | Prandtl number |
| Ec     | The Eckert number |
| L      | Characteristic length (m) |
| Gr_g   | Thermal Grashof number |
| Gr_m   | Local mass Grashof number |
| k_f    | Thermal diffusion ratio (m^{2}s^{-1}) |
| T_{in} | Ambient temperature (K) |
| T_{m}  | Mean fluid temperature (K) |
| T_{w}  | Wall surface temperature (K) |
| C_{oo} | Concentration in the fluid away from the surface (kgm^{-3}) |
| C_{os} | Concentration at the surface (kgm^{-3}) |
| Re     | Hydromagnetic Reynolds number |
| E      | Electric field strength (Vm^{-1}) |
| Sh     | Sherwood number |
| Nu     | Nusselt number |
| Ec     | Eckert number |
| u, v   | Dimensionless velocity components |
| x, y   | Cartesian coordinates |
| u^*, v^* | Nondimensional velocity components in the x* and y* directions |
| R      | Joules heating parameter |
| U_g    | Reference velocity (ms^{-2}) |
| q      | Velocity vector (ms^{-2}) |
| Pr     | Prandtl number |
| C_f    | Concentration susceptibility parameter (kmolm^{-3}) |
| C_p   | Specific heat at constant pressure (kg^{-1}k^{-1}) |
| k_s   | Mean absorption coefficient (m^2mol^{-1}) |
| C_{f_1} | The local skin friction coefficient due the primary velocity profiles |
| C_{f_2} | The local skin friction coefficient due the secondary velocity profiles |
| v      | Gradient operator |

Greek Symbols

| Symbol | Description |
|--------|-------------|
| β      | Volumetric coefficient of thermal expansion (K^{-1}) |
| σ      | Electrical conductivity (Ω^{-1}m^{-1}) |
| ρ      | Density (kgm^{-3}) |
| α      | Dynamic viscosity (m^{2}s^{-1}) |
| υ      | Kinematic viscosity (m^{2}s^{-1}) |
| α      | Thermal diffusivity (m^{2}s^{-1}) |
