We introduce in the present paper an intrinsic notion of "(effective) computability" in game semantics motivated by the fact that strategies in game semantics have been defined recursive if they are "computable in an extrinsic sense", i.e., they are representable by partial recursive functions, and so it has been difficult to regard game semantics as an autonomous foundation of computation. As a consequence, we have formulated a general notion of "algorithms" under the name of effective strategies, giving rise to a mathematical model of computation in the same sense as Turing machines but beyond computation on natural numbers, e.g., higher-order one, solely in terms of games and strategies. It subsumes computation of the programming language PCF, and so it is in particular Turing complete. Notably, effective strategies have a natural notion of types (i.e., games) unlike Turing machines, while they are non-inductively defined as opposed to partial recursive functions as well as semantic in contrast with λ-calculi and combinatory logic. Thus, in a sense, we have captured a mathematical (or semantic) notion of computation (and computability) that is more general than the "classical ones" in a fundamental level. Exploiting the flexibility of game semantics, our game-theoretic model of computation is intended to give a mathematical foundation of various (constructive) logics and programming languages.

1 Introduction

Game semantics [A+97, AM99, Hyl97] refers to a particular kind of semantics of logics and programming languages in which types and terms are interpreted as games and strategies, respectively. Historically, game semantics gave the first syntax-independent characterization of the programming language PCF [AJM00, HO00, Nic94], since then a variety of games and strategies have been proposed to model various programming features [Abr14, AM99]. An advantage of game semantics is this flexibility: It models a wide range of languages by simply varying constraints on strategies, which enables one to compare and relate different languages ignoring superfluous syntactic details. Its another characteristic is its conceptual naturality: It interprets syntax as dynamic interactions between Player and Opponent of a game, providing an intensional explanation of syntax in a natural and intuitive (yet mathematically precise) manner.

However, although game semantics has provided a unified framework to model various logics and programming languages, it has never been formulated as a mathematical model of computation in its own right in the same sense as Turing machines [Tur36, Koz12], the λ-calculus [Chu36, Chu40, B+84], combinatory logic [Sch24, Cur30], etc. More specifically, “(effective) computability” in game semantics has been always extrinsic [Abr14]: A strategy has been defined to be recursive if it is representable by a partial recursive function [AJM00, HO00]. This is mainly because a primal focus of the field has been full abstraction [Win93, Gun92], i.e., to characterize an observational equivalence in syntax in a syntax-independent manner; thus, it has not been concerned that much with (step-by-step) processes of computation. Nevertheless, it is unsatisfactory from a foundational point of view as it does not give much new insight on the notion of “effective computation”. Also, it raises an intriguing mathematical question in its own right: Is there any intrinsic (in the sense that it does not have recourse to the standard definition of computability) notion of “effective computability” in game semantics that is Turing complete (i.e., it contains every Turing-computable or partial recursive functions [Cut80, RR67])?

Motivated by the above consideration, in this paper we present the notion of effective strategies in game semantics defined solely in terms of games and strategies. Roughly, a strategy is finitary if its partial function representation that assigns the next Player’s move to a bounded size of partial history of previous moves, called its table, is finite, and effective if its table is “describable” by a finitary strategy. They give a reasonable notion of “computability” as finitary strategies are clearly “computable”, and so their “descriptions” can be “effectively read off”. Note that they are defined intrinsically in the sense stated above. The main idea is to allow strategies to look at only a bounded number of previous moves, and describe them by means that is clearly “effectively executable” but more expressive than finite tables, i.e., finitary strategies. This simple notion subsumes computation of the language PCF, and thus it is Turing complete, providing a positive answer to the question posted above. As a result, we have formulated a general notion of “algorithms”, which in turn gives rise to a mathematical model of computation in the same sense as Turing machines but beyond computation on natural numbers which we call the classical computation.

In hindsight, our game-theoretic model of computation may be seen as “interactive Turing machines” since its computation proceeds as an interaction between Player and Opponent, where Turing machines interact with Opponent only once as they just receive an input and produces an output (if it halts) once and for all, and the current position in a game serves as the current “state of mind” for effective strategies. It is this generalization of Turing machines that gives the game-theoretic model of computation an additional flexibility and computational power, inheriting their semantic and non-inductive nature.

To the best of our knowledge, effective strategies are the first intrinsic characterization of computability in game semantics that is Turing complete. Notably, they are non-inductively
defined as opposed to partial recursive functions, semantic in contrast with \(\lambda\)-calculi and combinatorial logic, and equipped with the notion of types, i.e., games, unlike Turing machines. Thus, in a sense, we have captured a mathematical notion of “computation” that is more general than the classical one, e.g., higher-order one [LN15], in a fundamental level. Therefore exploiting the flexibility of game semantics, our model of computation has a potential to give a mathematical foundation of a wide range of logics and programming languages.

The rest of the paper proceeds as follows. Defining our games and strategies in Section 2, we define effective strategies and show that they may interpret every term in the language PCF in Section 3. Finally, we make a conclusion and propose some future work in Section 4.

- **Notation.** We use the following notations throughout the paper:
  - We use bold letters \(s, t, u, v\), etc. for sequences, in particular \(e\) for the empty sequence, and letters \(a, b, c, d, m, n, x, y, z\), etc. for elements of sequences. We often abbreviate a finite sequence \(s = (x_1, x_2, \ldots, x_n)\) as \(x_1x_2\ldots x_n\) and write \(s_i\) as another notation for \(x_i\).
  - A concatenation of sequences is represented by a juxtaposition of them, but we write \(as, tb, uc\) for \((a)s, t(b), u(c)v\), etc. We sometimes write \(st\) for \(st\) for readability.
  - We write \(\text{even}(s)\) (resp. \(\text{odd}(s)\)) if \(s\) is of even-length (resp. odd-length). For a set \(S\) of sequences, we define \(S^{\text{even}} \overset{\text{df}}{=} \{s \in S \mid \text{even}(s)\}\) and \(S^{\text{odd}} \overset{\text{df}}{=} \{t \in S \mid \text{odd}(t)\}\).
  - We write \(s \preceq t\) if \(s\) is a prefix of \(t\). For a set \(S\) of sequences, \(\text{pref}(S) \overset{\text{df}}{=} \{s \mid \exists t \in S. s \preceq t\}\).
  - For a partially ordered set \(P\) and a subset \(S \subseteq P\), \(\text{sup}(S)\) denotes the supremum of \(S\).
  - \(X^* \overset{\text{df}}{=} \{x_1x_2\ldots x_n \mid n \in \mathbb{N}, \forall i \in \{1, 2, \ldots, n\}. x_i \in X\}\) for each set \(X\).
  - For a function \(f : A \rightarrow B\) and a subset \(S \subseteq A\), we define \(f \upharpoonright S : S \rightarrow B\) to be the restriction of \(f\) to \(S\). Also, \(f^* : A^* \rightarrow B^*\) is defined by \(f^*(a_1a_2\ldots a_n) \overset{\text{df}}{=} f(a_1)f(a_2)\ldots f(a_n)\).
  - Given sets \(X_1, X_2, \ldots, X_n\), for each \(i \in \{1, 2, \ldots, n\}\) we write \(\pi_i : X_1 \times X_2 \times \cdots \times X_n \rightarrow X_i\) for the \(i^\text{th}\)-projection function \((x_1, x_2, \ldots, x_n) \mapsto x_i\).
  - We write \(x \downarrow\) if an element \(x\) is defined and \(x \uparrow\) otherwise.

2 Preliminaries: dynamic games and strategies

This section presents our games and strategies. It is essentially the “dynamic refinement” of McCusker’s variant [AM99 McC98], which is proposed by the present author and Abramsky in [YA16]. Its main purpose is to refine the composition of strategies as “non-normalizing composition plus hiding” in order to capture dynamics and intensionality in computation. We have chosen this variant since the non-normalizing composition preserves “atomic computational steps” in strategies, and thus effective strategies are closed under it (but not under the usual composition). However, we need a minor modification: A particular implementation of tags for disjoint union of sets of moves (for constructions on games) has to be adopted as manipulations of the tags must be “effectively executable” by strategies, and strategies should behave “consistently” up to permutations of tags in exponential ! as in [AJM00 McC98].
2.1 On the tags for disjoint union of sets

In game semantics, we often take disjoint union of sets (of moves) when we form compound games such as tensor \( \otimes \), where we usually treat “tags” for such disjoint union informally for brevity [AM99, McC98]. However, since we are concerned with “effective computability”, including how to “effectively” handle “tags”, we have to formulate them rigorously. For this reason, we introduce:

**Definition 2.1.1** (Effective tags). An effective tag is a finite sequence over the alphabet \( \sum = \{\sharp, |\} \), where \( \sharp, | \) are arbitrarily fixed symbols. We write \( \sharp_i \) for \( | \ldots | \) for each \( i \in \mathbb{N} \).

**Definition 2.1.2** (Decoding and encoding). The decoding function \( \text{de} : \sum^* \rightarrow \mathbb{N}^* \) is defined by \( \text{de}(\gamma) \overset{\text{df}}{=} (i_1, i_2, \ldots, i_k) \in \mathbb{N}^* \) for all \( \gamma = i_1\sharp i_2\sharp \ldots \sharp i_{k-1}\sharp i_k \) and the encoding function \( \text{en} : \mathbb{N}^* \rightarrow \sum^* \) by \( \text{en}(j_1, j_2, \ldots, j_l) \overset{\text{df}}{=} j_1\sharp j_2\sharp \ldots \sharp j_{l-1}\sharp j_l \) for all \( (j_1, j_2, \ldots, j_l) \in \mathbb{N}^* \).

Clearly, the functions \( \text{de} : \sum^* \Rightarrow \mathbb{N}^* : \text{en} \) are mutually inverses (n.b. they both map \( e \) to itself). In fact, effective tags \( \gamma \) are to represent finite sequences \( \text{de}(\gamma) \) of natural numbers.

However, effective tags are not sufficient for our purpose: For “nested exponentials \( \mid \)”, we need to “effectively” associate a natural number to each finite sequence of natural numbers in an “effectively” invertible way. Of course it is possible as there is a computable bijection \( \langle \rangle : \mathbb{N}^* \rightarrow \mathbb{N} \) whose inverse is also computable by an elementary fact from computability theory [Cut80, RK67], but we cannot rely on it as we are aiming at developing an autonomous foundation of “effective computability”. On the other hand, this bijection is necessary only for manipulating effective tags, and so we would like to avoid an involved mechanism for it.

Our solution for this problem is to simply introduce some symbols to denote the bijection:

**Definition 2.1.3** (Extended effective tags). An extended effective tag is an expression \( e \in (\sum \cup \{\langle, \rangle\})^* \) generated by the rule \( e \overset{\text{df}}{=} \gamma|e_1;\sharp e_2|\langle e \rangle \), where \( \gamma \) ranges over effective tags.

**Definition 2.1.4** (Extended decoding). The extended decoding function \( \text{ede} : \mathcal{T} \rightarrow \mathbb{N}^* \) is defined by \( \text{ede}(\gamma) \overset{\text{df}}{=} \text{de}(\gamma) \), \( \text{ede}(e_1; e_2) \overset{\text{df}}{=} \text{ede}(e_1) \text{ede}(e_2) \), \( \text{ede}(\langle e \rangle) \overset{\text{df}}{=} \text{ede}(e) \), where \( \mathcal{T} \) is the set of extended effective tags, and \( \langle \rangle : \mathbb{N}^* \rightarrow \mathbb{N} \) is any computable bijection fixed throughout the present paper such that \( (i_1, i_2, \ldots, i_k) \neq (j_1, j_2, \ldots, j_l) \) whenever \( k \neq l \) (see, e.g., [Cut80]).

Of course, we lose the bijectivity between \( \sum^* \) and \( \mathbb{N}^* \) for extended effective tags, but in return, we may “symbolically execute” the bijection \( \langle \rangle : \mathbb{N}^* \rightarrow \mathbb{N} \) by just inserting \( \langle \rangle \). From now on, the word tags refers to extended effective tags, and we write \( e. f. g, h \) etc. for tags.

**Definition 2.1.5** (Tagged elements). A tagged element is any pair \( [m]_e \overset{\text{df}}{=} (m, e) \) with \( e \in \mathcal{T} \).

**Notation.** We often abbreviate a tagged element \( [m]_e \) as \( m \) if the tag \( e \) is not important.

2.2 Dynamic games

Our games are essentially dynamic games introduced in [YA16] equipped with an equivalence relation on positions that “ignores” permutations of tags in exponential ! as in [AM00, McC98].

The main idea of dynamic games is to introduce a distinction between internal and external moves; internal moves constitute “internal communication” between strategies, and they are to be a posteriori hidden by the hiding operation. Conceptually, internal moves are “invisible” to
satisfies $m$ or points $G$ in an arena interested in certain finite sequences of its moves equipped with a

Definition 2.2.2 (resp. $(\lambda$ transfinite ordinal $\lambda$)

Opponent as they represent how Player internally calculates the next external move. In this manner, dynamic games provide a “universe of computation” in which intensionality and dynamics in computation are represented by internal moves and the hiding operation, respectively. We first quickly review their basic definitions; see [YA16] for the details.

As games defined in [AM99, McC98], dynamic games are based on two preliminary concepts: arenas and legal positions. An arena defines basic components of a game, which in turn induces a set of legal positions that specifies the basic rules of the game.

Definition 2.2.1 (Arenas [YA16].) A (dynamic) arena is a triple $G = (M_G, \lambda_G, \vdash_G)$, where:

1. $M_G$ is a set of tagged elements called moves such that $\{\pi_1(m) | m \in M_G\}$ is finite
2. $\lambda_G : M_G \to \{O, P\} \times \{Q, A\} \times \mathbb{N}$ is a function called the labeling function, where $O, P, Q, A$ are arbitrarily fixed symbols, that satisfies $\sup((\lambda_G^N(m) | m \in M_G)) \in \mathbb{N}$
3. $\vdash_G \subseteq (\{\ast\} \cup M_G) \times M_G$ is a relation, where $\ast$ is an arbitrarily fixed symbol such that $\ast \notin M_G$, called the enabling relation that satisfies:
   - (E1) If $\ast \vdash_G m$, then $\lambda_G(m) = (O, Q, 0)$ and $n = \ast$ whenever $n \vdash_G m$
   - (E2) If $m \vdash_G n$ and $\lambda_G^A(n) = A$, then $\lambda_G^A(m) = Q$ and $\lambda_G^N(m) = \lambda_G^N(n)$
   - (E3) If $m \vdash_G n$ and $m \neq \ast$, then $\lambda_G^{OP}(m) \neq \lambda_G^{OP}(n)$
   - (E4) If $m \vdash_G n$, $m \neq \ast$ and $\lambda_G^{OP}(m) \neq \lambda_G^{OP}(n)$, then $\lambda_G^{OP}(m) = O$ (and $\lambda_G^{OP}(n) = P$)

in which $\lambda_G^{OP} \equiv \lambda_G; \pi_1 : M_G \to \{O, P\}$, $\lambda_G^{QA} \equiv \lambda_G; \pi_2 : M_G \to \{Q, A\}$, $\lambda_G^{N} \equiv \lambda_G; \pi_3 : M_G \to \mathbb{N}$.

A move $m \in M_G$ is initial if $\ast \vdash_G m$, an $O$-move (resp. a $P$-move) if $\lambda_G^{OP}(m) = O$ (resp. if $\lambda_G^{OP}(m) = P$), a question (resp. an answer) if $\lambda_G^{QA}(m) = Q$ (resp. if $\lambda_G^{QA}(m) = A$), and internal (resp. external) if $\lambda_G^{N}(m) > 0$ (resp. if $\lambda_G^{N}(m) = 0$). A sequence $s \in M_G$ is called $d$-complete ($d \in \mathbb{N} \cup \{\omega\}$) if it ends with an external or $d'$-internal move with $d' > d$, where $\omega$ is the least transfinite ordinal. We write $M_G^{\text{ext}}$ for the set of all initial moves in $G$.

That is, our variant of arena is an arena in [AM99] equipped with the degree of internality $\lambda_G^N$ on move $m$ and satisfying some additional axioms:

1. The set $\{\pi_1(m) | m \in M_G\}$ is required to be finite, so that each move is distinguishable.
2. The condition on the labeling function requires an upper bound of degrees of internality.
3. E1 adds $\lambda_G^N(m) = 0$ if $m \in M_G$ is initial as Opponent cannot “see” internal moves.
4. E2 additionally requires the degree of internality between a “QA-pair” to be the same.
5. E4 determines that only Player can make a move for a previous move if they have different degrees of internality because internal moves are “invisible” to Opponent.

From now on, the word arenas refers to the variant defined above. Given an arena, we are interested in certain finite sequences of its moves equipped with a justifying relation:

Definition 2.2.2 (Justified sequences [HO00, AM99, McC98].) A justified sequence ($j$-sequence) in an arena $G$ is a finite sequence $s \in M_G^\ast$ in which each non-initial move $n$ is associated with (or points at) a unique move $m$, called the justifier of $n$ in $s$, that occurs previously in $s$ and satisfies $m \vdash_G n$. We say that $n$ is justified by $m$, or there is a pointer from $n$ to $m$.

\footnote{We need all natural numbers for $\lambda_G^N$, not only the internal/external (I/E) distinction, to define a step-by-step execution of the hiding operation (see [YA16] for the details).}
Notation. We write $J_s(n)$ for the justifier of a non-initial move $n$ in a j-sequence $s$, where $J_s$ is the “function of pointers in $s$”, and $J_G$ for the set of all j-sequences in an arena $G$.

The idea is that each non-initial move in a j-sequence must be made for a specific previous move, called its justifier. Note that the first element $m$ of each non-empty j-sequence $ms \in J_G$ is an initial move in $G$; we call $m$ the opening move of $ms$ and write $O(ms)$ for it.

We may consider justifiers from the “external viewpoint”:

Definition 2.2.3 (External justifiers [YA16]). Let $G$ be an arena, and $s \in J_G$, $d \in \mathbb{N} \cup \{\omega\}$. Each non-initial move $n$ in $s$ has a unique sequence of justifiers $nm_1m_2 \ldots m_km$ ($k \geq 0$), i.e., $J_s(n) = m_1$, $J_s(m_1) = m_2$, ..., $J_s(m_{k-1}) = m_k$, $J_s(m_k) = m$, such that $m_1, m_2, \ldots, m_k$ are $d'$-internal with $0 < d' \leq d$ but $m$ is not. We call $m$ the $d$-external justifier of $n$ in $s$.

Notation. We usually write $J^d_s(n)$ for the $d$-external justifier of $n$ in a j-sequence $s$.

Definition 2.2.4 (External justified subsequences [YA16]). Let $s$ be a j-sequence in an arena $G$ and $d \in \mathbb{N} \cup \{\omega\}$. The $d$-external justified (j-) subsequence $H^d_s(s)$ of $s$ is obtained from $s$ by deleting $d$-internal moves, $0 < d' \leq d$, equipped with the pointers $J^d_s$.

Hiding operation on arenas [YA16]. Let $d \in \mathbb{N} \cup \{\omega\}$, and $G$ an arena. The arena $H^d(G)$ is defined by $M_{H^d(G)} \overset{df}{=} \{m \in M_G | \lambda^d_G(n) = 0 \lor \lambda^d_G(m) > d\}$, $\lambda^d_{H^d(G)} \overset{df}{=} \lambda^d_G | M_{H^d(G)}$, $\lambda^d_G \overset{df}{=} (\lambda^G, \lambda^G \downarrow n \mapsto \lambda^d_G(n) \circ d)$. $x \circ d = \begin{cases} x - d & \text{if } x \geq d \\ 0 & \text{otherwise} \end{cases}$ for all $x \in \mathbb{N}$, and $m \vdash_{H^d(G)} n \overset{df}{=} \exists k \in \mathbb{N}, m_1, m_2, \ldots, m_{2k-1}, m_{2k} \in M_G \setminus M_{H^d(G)} \setminus M_{H^d(G)} \setminus M_{H^d(G)}, m \vdash_G m_1 \land m_1 \vdash_G m_2 \land \cdots \land m_{2k-1} \vdash_G m_{2k} \land m_{2k} \vdash_G n$ (note that $m \vdash_G n$ if $k = 0$).

I.e., $H^d(G)$ is obtained from $G$ by deleting all $d$-internal moves, $0 < d' \leq d$, decreasing by $d$ the degree of internality of the remaining moves and “concatenating” the enabling relation to form the “$d$-external” one. We clearly have:

Lemma 2.2.6 (Closure of arenas and j-sequences under hiding [YA16]). If $G$ is an arena, then so is $H^d(G)$ for all $d \in \mathbb{N} \cup \{\omega\}$ such that $H^0(G) = G$ and $H^d_0(s) \in J_G$ for all $s \in J_G$.

Next, let us recall the notion of “relevant part” of previous moves, called views:

Definition 2.2.7 (Views [HO00, AM99, McC98]). Given a j-sequence $s$ in an arena $G$, we define the Player view (P-view) $[s]_G$ and the Opponent view (O-view) $[s]_G$ by induction on the length of $s$ as follows:

- $[\epsilon]_G \overset{df}{=} \epsilon$
- $[sm]_G \overset{df}{=} [s]_G.m$ if $m$ is a P-move
- $[sm]_G \overset{df}{=} m$ if $m$ is initial
- $[smtn]_G \overset{df}{=} [s]_G.m$ if $n$ is an O-move with $J_{smtn}(n) = m$
- $[\epsilon]_G \overset{df}{=} \epsilon$
- $[sm]_G \overset{df}{=} [s]_G.m$ if $m$ is an O-move
- $[smtn]_G \overset{df}{=} [s]_G.m$ if $n$ is a P-move with $J_{smtn}(n) = m$
where the justifiers of the remaining moves in $[s]_G$ (resp. $[s]_G$) are unchanged if they occur in $[s]_G$ (resp. $[s]_G$) and undefined otherwise.

- **Notation.** We omit the subscript $G$ in $[s]_G$, $[s]_G$ when the underlying game $G$ is obvious.

  The idea behind this definition is as follows. Given a “position” or prefix $tm$ of a $j$-sequence $s$ in an arena $G$ such that $m$ is a $P$-move (resp. an $O$-move), the $P$-view $[t]$ (resp. the $O$-view $[t]$) is intended to be the currently “relevant” part of $t$ for Player (resp. Opponent). That is, Player (resp. Opponent) is concerned only with the last $O$-move (resp. $P$-move), its justifier and that justifier’s “concern”, i.e., $P$-view (resp. $O$-view), which then recursively proceeds.

  We are now ready to define:

- **Definition 2.2.8** (Legal positions [YA16]). A (dynamic) legal position in an arena $G$ is a sequence $s \in M^*_G$ (equipped with justifiers) that satisfies:
  
  - **Justification.** $s$ is a $j$-sequence in $G$.
  - **Alternation.** If $s = s_1 m n s_2$, then $\lambda^O_G(m) \neq \lambda^O_G(n)$.
  - **Generalized visibility.** If $s = t m u$ with $m$ non-initial and $d \in \mathbb{N} \cup \{\omega\}$ satisfy $\lambda_G(m) = 0 \lor \lambda_G(m) > d$, then $\mathcal{J}_s(m)$ occurs in $[H_G^d(t)]_{H^d(G)}$ if $m$ is a $P$-move, and it occurs in $[H_G^d(t)]_{H^d(G)}$ if $m$ is an $O$-move.
  - **IE-switch.** If $s = s_1 m n s_2$ with $\lambda_G(m) \neq \lambda_G(n)$, then $m$ is an $O$-move.

- **Notation.** We write $L_G$ for the set of all legal positions in an arena $G$.

  I.e., our (dynamic) legal positions are legal positions in [AM99] satisfying additional axioms:

  - **Generalized visibility** is a natural generalization of visibility [HO00, AM99, McC98]; it requires that visibility holds after any iteration of the “hiding operation on arenas” [YA16].
  - **IE-switch** states that only Player can change the degree of internality during a play because internal moves are “invisible” to Opponent.

From now on, the word **legal positions** refers to the variant defined above by default.

Next, note that in a legal position in an arena, there may be several initial moves; the legal position consists of chains of justifiers initiated by such initial moves, and chains with the same initial move form a thread. Formally,

- **Definition 2.2.9** (Threads [AM99, McC98]). Let $G$ be an arena, and $s \in L_G$. Assume that $m$ is an occurrence of a move in $s$. The chain of justifiers from $m$ is a sequence $m_0 m_1 \ldots m_k \in M^*_G$ such that $k \geq 0$, $m_k = m$, $J_s(m_k) = m_{k-1}$, $J_s(m_{k-1}) = m_{k-2}$, ..., $J_s(m_1) = m_0$, and $m_0$ is initial. In this case, we say that $m$ is hereditarily justified by $m_0$. The subsequence of $s$ consisting of the chains of justifiers in which $m_0$ occurs is called the thread of $m_0$ in $s$. An occurrence of an initial move is often called an initial occurrence.

- **Notation.** We write $s \upharpoonright I$, where $s \in L_G$ and $I$ is a set of initial occurrences in $s$, for the subsequence of $s$ consisting of threads of initial occurrences in $I$, and define $s \upharpoonright m \overset{df}{=} s \upharpoonright \{m\}$.

  We are now ready to define our variant of games:

- **Definition 2.2.10** (Games). A (dynamic) game is a tuple $G = (M_G, \lambda_G, \vdash_G, P_G, \simeq_G)$, where:
  
  - The triple $(M_G, \lambda_G, \vdash_G)$ forms an arena
\textbf{Example 2.2.14.} The \textit{terminal game} $I$ is defined by $I \overset{\text{df}}{=} (\emptyset, \emptyset, \emptyset, \{\emptyset, \emptyset\})$.

\textbf{Example 2.2.13.} The \textit{boolean game} $2$ is defined by:

- $M_2 \overset{\text{df}}{=} \{q, \top, \bot\}$, where each move has the empty tag $\epsilon$
- $\lambda_2 : q \mapsto (O, Q, 0), \top \mapsto (P, A, 0), \bot \mapsto (P, A, 0)$
- $\vdash_2 \overset{\text{df}}{=} \{(\ast, q), (q, \top), (q, \bot)\}$
- $P_2 \overset{\text{df}}{=} \text{pref}(\{(q, \top, q, \bot)\})$, where each non-initial move is justified by $q$
- $s \simeq_2 t \overset{\text{df}}{\Rightarrow} s = t$.

The positions $q, \top, q, \bot$ are intended to represent \textit{true} and \textit{false}, respectively.

\textbf{Example 2.2.14.} The \textit{natural number game} $N$ is defined by:

- $M_N \overset{\text{df}}{=} \{\hat{q}, q, \ast, \hat{\bullet}\}$, where each move has the tag $\epsilon$, and we often abbreviate $\hat{q}$ as $q$
- $\lambda_N : \hat{q} \mapsto (O, Q, 0), q \mapsto (O, Q, 0), \ast \mapsto (P, A, 0), \hat{\bullet} \mapsto (P, A, 0)$
- $\vdash_N \overset{\text{df}}{=} \{\ast, \hat{q}, (q, \hat{b}), (q, \hat{\bullet}), (q, b), (q, \bullet), (\bullet, q)\}$
- $P_N \overset{\text{df}}{=} \text{pref}(\{\hat{q}(\cdot, q)^n.b | n \in \mathbb{N}\})$, where each non-initial move is justified by the last move
- $s \simeq_N t \overset{\text{df}}{\Rightarrow} s = t$.

The position $\hat{q}(\cdot, q)^n.b$ is to represent $n \in \mathbb{N}$. Let us define $n \overset{\text{df}}{=} \text{pref}(\{\hat{q}(\cdot, q)^n.b\})^{\text{even}}$. 

\textbf{Definition 2.2.11} (Finitely well-opened games). A game $G$ is \textit{finitely well-opened} if $[m]_e \in M_G^{\text{fin}}$ implies $e = \epsilon$, and $s, [m] \in P_G$ with $[m]$ initial implies $s = \epsilon$.

I.e., a game is finitely well-opened if it is \textit{well-opened} \cite{AM99, McC98} and its initial moves have the empty tag $\epsilon$ only. From now on, \textit{games} refer to finitely well-opened (dynamic) games.
Example 2.2.15. The tag game $G(T)$ is defined by:

- $M_{G(T)} \triangleq \{\hat{q}_{T}, q_{T}, \varepsilon, \emptyset, \},$ where each move has the tag $\varepsilon$, and $\hat{q}_{T}$ is often written $q_{T}$.
- $\lambda_{G(T)} : \hat{q}_{T} \mapsto (O, Q, 0), q_{T} \mapsto (O, Q, 0), \varepsilon \mapsto (P, A, 0),$ where $\varepsilon \in \{\varepsilon, \varepsilon, \varepsilon\}$.
- $\Gamma_{G(T)} \triangleq \{((x, y)) \mid x \in \{\hat{q}_{T}, q_{T}\}, y \in \{\varepsilon, \varepsilon, \varepsilon\}\} \cup \{(e, q_{T}) \mid e \in \{\varepsilon, \varepsilon, \varepsilon\}\}$
- $P_{G(T)} \triangleq \text{pref}(\hat{q}_{T} e_{1} q_{T} e_{2} \ldots q_{T} e_{k} q_{T} \varepsilon \mid k \in \mathbb{N}, e_{1} e_{2} \ldots e_{k} \in T),$ where each non-initial move is justified by the last move.

$s \simeq_{G(T)} t \iff s = t.$

The position $\hat{q}_{T} e_{1} q_{T} e_{2} \ldots q_{T} e_{k} q_{T} \varepsilon$ is intended to represent the tag $e_{1} e_{2} \ldots e_{k} \in T.$

Definition 2.2.16 (Subgames). A subgame of a game $G$ is a game $H$ that satisfies $M_H \subseteq M_G$, $\lambda_H = \lambda_G | M_H, \Gamma_H \subseteq \Gamma_G \cap \{\star\} \cup M_H, P_H \subseteq P_G, \simeq_H \subseteq \simeq_G.$ In this case, we write $H \subseteq G.$

Definition 2.2.17 (Hiding operation on games [YA16]). The d-hiding operation $\mathcal{H}^{d}$ on games for each $d \in \mathbb{N} \cup \{\omega\}$ is defined as follows. Given a game $G$, $\mathcal{H}^{d}(G)$ is the game such that $(M_{\mathcal{H}^{d}(G)}, \lambda_{\mathcal{H}^{d}(G)}, \Gamma_{\mathcal{H}^{d}(G)})$ is the arena $\mathcal{H}^{d}(G), P_{\mathcal{H}^{d}(G)} \triangleq \{H_{\mathcal{H}^{d}(G)}(s) \mid s \in P_G\},$ and $\mathcal{H}^{d}(s) \simeq_{\mathcal{H}^{d}(G)} \mathcal{H}^{d}(t) \iff s \simeq_{\mathcal{H}^{d}(G)} t.$ A game $G$ is static if $\mathcal{H}^{\omega}(G) = G.$

Theorem 2.2.18 (Closure of games under hiding). For any game $G$, $\mathcal{H}^{d}(G)$ forms a well-defined game for all $d \in \mathbb{N} \cup \{\omega\}$. Moreover, if $H \subseteq G$, then $\mathcal{H}^{d}(H) \subseteq \mathcal{H}^{d}(G)$ for all $d \in \mathbb{N} \cup \{\omega\}.$

Proof. First, $\simeq_{\mathcal{H}^{d}(G)}$ is well-defined as $\mathcal{H}^{d}(G) \simeq_{\mathcal{H}^{d}(G)} \mathcal{H}^{d}(t)$ does not depend on the representatives $s, t \in P_G$. By the corresponding result in [YA16], it suffices to verify the preservation of the axioms 11, 12, 13 under $\mathcal{H}^{d}$. Then 11, 12 for $\mathcal{H}^{d}(G)$ immediately follow from 12 on $G$. For 13, if $H_{\mathcal{H}^{d}(G)}(s) \simeq_{\mathcal{H}^{d}(G)} H_{\mathcal{H}^{d}(G)}(t)$ and $H_{\mathcal{H}^{d}(G)}(s).m \in P_{\mathcal{H}^{d}(G)}$, we can assume $d \neq \omega \land d' \neq \omega$ since otherwise 13 on $\mathcal{H}^{d}(G)$ is reduced to that on $G$, then $\exists s' m \in P_G, H_{\mathcal{H}^{d}(G)}(s') = H_{\mathcal{H}^{d}(G)}(s).m$ and $H_{\mathcal{H}^{d+d'}(s')} = H_{\mathcal{H}^{d+d'}(s)} \simeq_{\mathcal{H}^{d+d'}(G)} H_{\mathcal{H}^{d+d'}(t)}$ (see [YA16] for the proof). Thus by 13 on $G$, we can conclude $\exists t_0 \in P_G. H_{\mathcal{H}^{d}(G)}(t_0) \simeq_{\mathcal{H}^{d}} H_{\mathcal{H}^{d+d'}}(t_0),$ whence $\exists t_0 \in P_{\mathcal{H}^{d}(G)}, H_{\mathcal{H}^{d}(G)}(t_0) = H_{\mathcal{H}^{d}(G)}(s').$ Finally for $H \subseteq G \Rightarrow \mathcal{H}^{d}(H) \subseteq \mathcal{H}^{d}(G),$ again by the result in [YA16] it suffices to show $\simeq_{H} \subseteq \simeq_{G} \Rightarrow \simeq_{\mathcal{H}^{d}(H)} \subseteq \simeq_{\mathcal{H}^{d}(G)},$ but it is immediate from the definition.

At the end of the present section, we define constructions on games based on the standard ones [McC98,AM99,YA16] with tags explicit, equipping them with constructions on identifications of positions. For this, like variable convention [Han94], we assume that there are countably infinite copies of the symbols $|, \oplus$, and write $\alpha_\lambda, \gamma_\beta,$ etc., where $\alpha, \beta \in \{0, 1\}^\ast$, for these copies. However, for readability, we usually omit these subscripts $\alpha$ unless necessary. Also, we define $e_\alpha \triangleq (e_1)e_2 \ldots (e_k)$ for all $e = e_1 e_2 \ldots e_k \in T$, $\alpha \in \{0, 1\}^\ast$.

Definition 2.2.19 (Tensor [AM99,McC98]). The tensor (product) $A \otimes B$ of games $A, B$ is defined by:

- $M_{A \otimes B} \triangleq \{(m, 0)_{e_0} \mid m \in M_A \} \cup \{(m', 1)_{e'} \mid m' \in M_B\}$
- $\lambda_{A \otimes B}([m, i]_{e}) \triangleq \begin{cases} \lambda_A([m]_{e}) & \text{if } i = 0 \\ \lambda_B([m]_{e}) & \text{if } i = 1 \end{cases}$
\[ \lambda_{A \rightarrow B}([m, i]_{e}), \ \text{df} \ \ (i = 0 \wedge \ast \vdash_{A} [m]_{e} \vee (i = 1 \wedge \ast \vdash_{B} [m]_{e}) \]

\[ [(m, i)]_{e}, \ \ast \vdash_{A \rightarrow B}([m', j]_{e'}), \ \text{df} \ \ ((i = 0 = j \wedge [m]_{e} \vdash_{A} [m']_{e'}) \vee (i = 1 = j \wedge [m]_{e} \vdash_{B} [m']_{e'}) \]

\[ P_{A \rightarrow B}, \ \text{df} \ \ \{ s \in L_{A \rightarrow B} | s \vdash 0 \in P_{A}, s \vdash 1 \in P_{B} \} \]

\[ s \simeq_{A \rightarrow B} t, \ \text{df} \ \ (\pi_{2} \circ \pi_{1})^{*}(s) = (\pi_{2} \circ \pi_{1})^{*}(t) \land s \vdash 0 \simeq_{A} t \land 0 \wedge s \vdash 1 \simeq_{B} t \land 1. \]

**Definition 2.2.20** (Linear implication [AM99] [McC98]). The *linear implication* \( A \rightarrow B \) from a static game \( A \) to another game \( B \) is defined by:

\[ M_{A \rightarrow B}, \ \text{df} \ \ \{ ([m, 0]_{e_{0}} | [m]_{e} \in M_{A}) \cup ([m', 1]_{e'} | [m']_{e'} \in M_{B}) \} \]

\[ \lambda_{A \rightarrow B}([m, i]_{e}), \ \text{df} \ \ \begin{cases} \lambda_{A}([m]_{e}) & \text{if } i = 0 \\ \lambda_{B}([m]_{e}) & \text{if } i = 1 \end{cases} \]

\[ \ast \vdash_{A \rightarrow B}([m, i]_{e}), \ \text{df} \ \ i = 1 \wedge \ast \vdash_{B} [m]_{e} \]

\[ [(m, i)]_{e}, \ \ast \vdash_{A \rightarrow B}([m', j]_{e'}), \ \text{df} \ \ ((i = 0 = j \wedge [m]_{e} \vdash_{A} [m']_{e'}) \vee (i = 1 = j \wedge [m]_{e} \vdash_{B} [m']_{e'}) \]

\[ P_{A \rightarrow B}, \ \text{df} \ \ \{ s \in L_{A \rightarrow B} | s \vdash 0 \in P_{A}, s \vdash 1 \in P_{B} \} \]

**Definition 2.2.21** (Product [AM99] [McC98]). The *product* \( A \& B \) of games \( A, B \) is defined by:

\[ M_{A \& B}, \ \text{df} \ \ \{ ([m, 0]_{e_{0}} | [m]_{e} \in M_{A}) \cup ([m', 1]_{e'} | [m']_{e'} \in M_{B}) \} \]

\[ \lambda_{A \& B}([m, i]_{e}), \ \text{df} \ \ \begin{cases} \lambda_{A}([m]_{e}) & \text{if } i = 0 \\ \lambda_{B}([m]_{e}) & \text{if } i = 1 \end{cases} \]

\[ \ast \vdash_{A \& B}([m, i]_{e}), \ \text{df} \ \ (i = 0 \wedge \ast \vdash_{A} [m]_{e} \vee (i = 1 \wedge \ast \vdash_{B} [m]_{e}) \]

\[ [(m, i)]_{e}, \ \ast \vdash_{A \& B}([m', j]_{e'}), \ \text{df} \ \ ((i = 0 = j \wedge [m]_{e} \vdash_{A} [m']_{e'}) \vee (i = 1 = j \wedge [m]_{e} \vdash_{B} [m']_{e'}) \]

**Definition 2.2.22** (Generalized product [YA16]). The *generalized product* \( L \& R \) of games \( L, R \) such that \( \mathcal{H}^{\omega}(L) \leq C \rightarrow A, \mathcal{H}^{\omega}(R) \leq C \rightarrow B \) for some static games \( A, B, C \) is defined by:

\[ M_{L \& R}, \ \text{df} \ \ \{ ([m, 0]_{e_{0}} | [m]_{e} \in M_{(C, 0)} \cap (M_{L} \cup M_{R})) \cup ([m', 0]_{e_{0}} | [m']_{e'} \in M_{L} \setminus M_{(C, 0)}) \cup ([m', 1]_{e'} | [m']_{e'} \in M_{R} \setminus M_{(C, 0)}), \text{where } M_{(C, 0)}, \ \text{df} \ \ ([c, 0]_{e_{0}} | [c]_{e} \in M_{C}) \}

\[ \lambda_{L \& R}([m, i]_{e}), \ \text{df} \ \ \begin{cases} \lambda_{C}([c]_{e'}) & \text{if } [m, i]_{e_{1}} = ([c, 0], 0)_{e_{0}} and ([c, 0]_{e_{0}})_{e_{0}'}, \in M_{(C, 0)} \\ \lambda_{L}([m]_{e}) & \text{if } i = 0 \text{ and } [m]_{e} \notin M_{(C, 0)} \\ \lambda_{R}([m]_{e}) & \text{if } i = 1 \end{cases} \]
\[\ast \vdash_{L \& R} [(m, i)_e, \text{df}] \iff (i = 0 \land \ast \vdash_L [m]_e) \lor (i = 1 \land \ast \vdash_R [m]_e)\]

\[\ast \vdash_{L \& R} [(m', j)]_{e'} \iff (i = 0 = j \land [m]_e \vdash_L [m']_e) \lor (i = 1 = j \land [m]_e \vdash_R [m']_e)\]

\[\ast \vdash_{L \& R} [\pi_1 \circ \pi_1]^* (s) = (\pi_2 \circ \pi_1)^* (t) \land L \succeq_L t \land L \land s \vdash R \succeq_R t \land R.\]

**Definition 2.2.23 (Exponential \textbf{McC98}).** The exponential !A of a game A is defined by:

\[M_A \text{df} = \{[(m, i)_e]_{e'} \mid [m]_e \in M_A, f \in T\} \text{ and } \lambda_A[(m, f)]_{e'} \text{df} = \lambda_A[(m)]_e\]

\[\ast \vdash_{L \& R} [m]_{e'} \iff \ast \vdash_A [m]_{e} \text{ and } [m]_{e'} \vdash_A [m']_{e'} \text{df} = \exists f \land \lambda_A [m]_{e'} \vdash_A [m']_{e'}\]

\[P_A \text{df} = \{s \in L_A \mid \forall i \in \mathbb{N}, s \vdash P_A\}, \text{ where } s \vdash i \text{ is the subsequence of } s \text{ consisting of moves } [m]_{e'} \text{ such that } ede((f)) = i \text{ but changed into } [m]_{e} \]

\[s \succeq_{L \& R} t \text{df} \iff \exists \theta \in \mathcal{P}(\mathbb{N}). (\pi_1 \circ \theta \circ \pi_2)^* (s) = (\theta \circ \pi_2)^* (t) \land \forall i \in \mathbb{N}, s \vdash \theta(i) \succeq_A t \land i, \text{ where } \mathcal{P}(\mathbb{N}) \text{ denotes the set of all permutations of natural numbers.}\]

I.e., our exponential !A is a slight modification of the one in [McC98] by generalizing threads \([m]_{e}\) to \([m]_{e'}\) \((m, e) \in M_A\). Since we are focusing on well-opened games A, there is at most one thread with a tag \((f)_{e'}\) such that \(ede((f)) = i\) for each \(i \in \mathbb{N}\) in a position of !A. As a consequence, our exponential !A is the same as the one in [McC98] except that there is a choice in the implementation \((f)\) of tags \(i \in \mathbb{N}\) (but that implementation \((f)\) is unique within !A).

**Definition 2.2.24 (Concatenation \textbf{YA16}).** Let \(J, K\) be games such that \(H^-(J) \subseteq A \rightarrow B\), \(H^-(K) \subseteq B \rightarrow C\) for some static games \(A, B, C\). Their concatenation \(J \upharpoonright K\) is defined by:

\[M_{J \upharpoonright K} \text{df} = \{[(m, 0)_e]_{e_0} \mid [m]_e \in M_J\} \cup \{[(m', 1)]_{e'} \mid [m']_{e'} \in M_K\}\]

\[\lambda_{J \upharpoonright K}[(m, i)]_{e} \text{df} \begin{cases} \lambda_{J}^{\mu}[(m)]_e & \text{if } i = 0 \text{ and } [m]_e \text{ comes from } B \\ \lambda_{J}^{\mu}[(m)]_e & \text{if } i = 0 \text{ and } [m]_e \text{ does not come from } B \\ \lambda_{K}^{\mu}[(m)]_e & \text{if } i = 1 \text{ and } [m]_e \text{ comes from } B \\ \lambda_{K}^{\mu}[(m)]_e & \text{if } i = 1 \text{ and } [m]_e \text{ does not come from } B \\ \end{cases}\]

is defined by \(\mu \text{df} \iff \sup(\{\lambda_{J}^{\mu}[(m)]_e \mid [m]_e \in M_J\} \cup \{\lambda_{K}^{\mu}[(m)]_e \mid [m']_{e'} \in M_K\}) + 1 ; \quad \lambda_{G}^{\mu} \text{df} \iff \lambda_{G}^{\mu} \iff \lambda_{G}^{\mu} : n \rightarrow \lambda_{G}^{\mu}(n) + \mu \text{ for any game } G\)

\[\ast \vdash_{L \& K} [(m, i)_e]_{e_0} \iff i = 1 \land \ast \vdash_{K} [m]_e\]

\[\ast \vdash_{L \& K} [(m', j)]_{e'} \iff (i = 0 = j \land [m]_e \vdash_{J} [m']_{e'}) \lor (i = 1 = j \land [m]_e \vdash_{K} [m']_{e'})\]

\[P_{J \upharpoonright K} \text{df} = \{s \in \mathcal{J}_{J \upharpoonright K} \mid s \vdash P_J, s \vdash P_K, s \vdash B_1, B_2 \in \text{pr}_B\}, \text{ where } B_1, B_2 \text{ are the two copies of } B, s \vdash B_1, B_2 \text{ is the subsequence of } s \text{ consisting of moves in } B_1, B_2 \text{, i.e., external moves } [(m, i)]_{e} \text{ such that } (i = 1 \lor j = 0) \lor (i = 0 \land j = 1), \text{ with the justifiers in } s \text{ but changed into } [(m, i)]_{e}, \text{ pr}_B \text{df} \iff \{t \in P_{B \rightarrow B} \mid \forall u \leq t. \text{ even}(u) \Rightarrow u \vdash u = u \land 1\}\]
Definition 2.2.3

\[ (\pi_2 \circ \pi_1)^*(s) = (\pi_2 \circ \pi_1)^*(t) \land s \downarrow t \lor 0 \land s \mid 1 \]
3 Effective strategies

We have presented our variant of games and strategies. In this main section, we introduce an intrinsic notion of “effective computability” of strategies that subsumes computation of the programming language PCF [Plo77, Mit96], and so it is Turing complete in particular.

Notation. We often write $A \Rightarrow B$ or $A \Rightarrow \Rightarrow B$ for the linear implication $A \rightarrow B$ for any games $A, B$. The operations $\rightarrow, \Rightarrow, \Rightarrow \Rightarrow$ are all right associative.

3.1 Effective strategies

As history-free strategies are expressive enough to model the language PCF [AJM00], it suffices for our strategies to refer to at most three last moves in the P-view and the (“semi”) opening moves of the position, which is clearly “effective”. Thus, it remains to formulate the notion of “effective computability” of the next move from such a bounded number of previous moves.

Since the set $\{ \langle m \rangle | \langle m \rangle \in M_G \}$ is finite for any game $G$, finitary innocent [HO00, AM99, McC98] strategies in the sense that their view functions [HO00, McC98] are finite seem sufficient at first glance. However, to model the fixed-point combinators in PCF, strategies need to be able to initiate new threads unboundedly many times [HO00, AJM00]; also, they have to model promotion (\_)† for which infinitely many manipulations of tags are necessary. Thus, finitary strategies are not strong enough.

Then how can we define a stronger notion of “effective computability” of the next move from previous moves solely in terms of games and strategies? Our solution is as follows. A strategy $\sigma : G$ is effective if it is “describable” by a finitary strategy on the instruction game:

**Definition 3.1.1** (Instruction games). Given a game $G$, its instruction game $G(M_G)$ is the product $G(\pi_1(M_G)) \& G(T)$, where the component game $G(\pi_1(M_G))$ is defined by:
\( M_{G(π(M_G))} \overset{df}{=} \{ qG, □ \} \cup π_1(M_G) \), where \( qG, □ \) are arbitrarily chosen with \( qG \not∈ π_1(M_G) \), \( □ \not∈ π_1(M_G) \), and each move has the empty tag \( ε \).

- \( λ_G(π(M_G)) : G ↦ (O, Q, 0), (m ∈ π_1(M_G)) ↦ (P, A, 0), □ ↦ (P, A, 0) \)
- \( Γ_G(π(M_G)) \overset{df}{=} \{(\ast, qG), (qG, □)\} \cup \{(qG, m) | m ∈ π_1(M_G)\} \)
- \( P_G(π(M_G)) \overset{df}{=} \text{pref}(\{qG.m | m ∈ π_1(M_G)\} \cup \{qG.□\}) \), where \( qG \) justifies \( m \) and \( □ \)

\( s ≜ G(π(M_G)) t \overset{df}{=} s = t \).

The positions \( qG.m, qG.□ \) are to represent \( m ∈ π_1(M_G) \), “no element”, respectively.

- **Notation.** Given a sequence \( s = x_kx_{k-1} \ldots x_1 \) ∈ \( M_G^* \) of moves in an arena \( G \) and a number \( l ∈ \mathbb{N} \), we define \( s | l = \begin{cases} s & \text{if } l ≥ k \\ x_kx_{k-1} \ldots x_l & \text{otherwise.} \end{cases} \) A function \( f : π_1(M_G) \rightarrow \{\top, \bot\} \) induces another \( f^* : G_φ \rightarrow π_1(M_G)^* \) by \( f([m_k]_{e_k}[m_{k-1}]_{e_{k-1}} \ldots [m_1]_{e_1}) \overset{df}{=} m_km_{i-1} \ldots m_i, l ≤ k \), where \( m_i m_{i-1} \ldots m_1 \) is a subsequence of \( m_k m_{k-1} \ldots m_1 \) that consists of \( m_i \) such that \( f(m_i) = \top \).

- **Notation.** Let \( G \) be a game, and \( [m]_e \in M_G, e = e_1e_2 \ldots e_k ∈ T \). We write \([m]_e\) for the strategy \( (m, \varepsilon) : G(M_G), \) where \( m : G(π(M_G)), \varepsilon : G(T) \) are defined by \( m \overset{df}{=} \text{pref}([qG,m])^\text{even} \), \( \varepsilon \overset{df}{=} \text{pref}([qG,□])^\text{even} : G(π_1(M_G)) \), and \( \varepsilon_n \overset{df}{=} ([□] \ldots [□], [m[1]_{e[1]}], [m[2]_{e[2]}] \ldots [m[1]_{e[1]}]) : G(M_G)^n \overset{df}{=} G(M_G) \cup \varepsilon \cup G(M_G)^n \), where the pairing and product are left associative. Given a strategy \( σ : G(M_G) \), we define \( M(σ) ∈ G(M_G) \) to be the unique move such that \( M(σ) = σ \) if it exists, and undefined otherwise.

We will be particularly concerned with games \( P_{G(M_G)} \overset{df}{=} G(M_G) \) shortly. The symbols \( (.) \) in any position \( s ∈ P_{G(M_G)} \overset{df}{=} G(M_G) \) form unique pairs similarly to “QA-pairs” for bracketing condition \( [HO00][AM99] \). Specifically, each \( ) \) is paired with the most recent “still unpaired” \( ( \) in the same component game \( G(T) \); one is called the mate of the other. Moreover, we define:

**Definition 3.1.2** (M-views). Let \( G \) be a game. The matching view (m-view) \( [s]_G \) (we often abbreviate it as \( [s] \)) of a position \( s ∈ P_{G(M_G)} \overset{df}{=} G(M_G) \) is defined by: \( [ε]_G \overset{df}{=} ε, [s.(t.)]_G \overset{df}{=} [s]_G.(\cdot), \) where \( ( \cdot \) is the mate of \( ), \) and \( [sm]_G \overset{df}{=} [s]_G.m, m \not= \cdot \).

We are now ready to make the notion of “describable by a finitary strategy” precise.

**Definition 3.1.3** (Algorithms). An algorithm \( A \) on a game \( G \), written \( A :: G \), is a collection \( A = (A_m)_{m∈\mathcal{S}_A} \) of finite partial functions \( A_m : \partial_m(P_{G(M_G)} \overset{df}{=} G(M_G)) \rightarrow M_{G(M_G)} \overset{df}{=} G(M_G) \), where \( \mathcal{S}_A \subseteq π_1(M_G)^* \setminus \{ε\} \) is a finite set of states, \( \partial_m(tx) \overset{df}{=} (O(tx)), [tx] | [A_m], [tx] | [A_m]) \) for all \( tx ∈ P_{G(M_G)} \overset{df}{=} G(M_G) \), \( [A_m], [A_m] ∈ \mathbb{N} \) are the scopes of \( A_m \), and \( A_m \) also specifies the justifier of each output equipped with the query function \( Q_A : π_1(M_G) \rightarrow \{\top, \bot\} \) such that \( [m] ∈ M_G^{\text{Init}} \Rightarrow Q_A(m) = \top \) and \( Q_A(m) = \top \Rightarrow ∃ e ∈ T. [m]_e ∈ M_G \) is initial or internal.

**Remark.** Note that \( Q_A(s) = ε \) for any \( s ∈ \mathcal{S}_G \setminus \{ε\} \) since \( [m] ∈ M_G^{\text{Init}} \Rightarrow Q_A(m) = \top \).

\(^2\)But we usually treat this structure implicit as in \([AM99][Mc98]\).
Convention. Since we shall focus on consistent strategies of the form \( A \Rightarrow B \) in this paper, it is reasonable to require each algorithm \( A \) not to refer to any outer tags when it computes the next internal element. Also, since a strategy of our interest modifies (i.e., not just “copy-cats”) the outer tag of the last move only if it initiates a new thread in the domain game, we assume that the only outer tag \( A \) investigates when it computes the next outer tag is just the one of the last move in the P-view, and it reads it off at most once. We call algorithms that satisfy these two conditions standard; from now on, the word algorithms refers to standard ones by default. Algorithms in this paper are all standard, and standard algorithms are closed under all constructions on algorithms we shall introduce later. This convention will save work in the proof to show the closure property of effective strategies under promotion (see Theorem 3.3.9).

Example 3.1.7. The zero strategy \( \text{zero} \) \( \overset{df}{=} \text{pref}(\{[q_1]|p_1]\})^\text{even} : [I_0]|e| \Rightarrow [N_1] \) is effective since we may give an algorithm \( A(\text{zero}) \) by \( \mathcal{A}_A(\text{zero})(m) \overset{df}{=} \begin{cases} \top & \text{if } m = q_1; \mathcal{A}_A(\text{zero}) \overset{df}{=} \{q_1\}, \\
\bot & \text{otherwise, } \mathcal{A}_A(\text{zero}) \overset{df}{=} \{q_1\}, \end{cases} \)

\(|A(\text{zero})|_q \overset{df}{=} 1 \) and \( A(\text{zero})|_q : [q \Rightarrow N]|_1 \mapsto [p_1]|_1 \rightarrow [\checkmark]|_1. \) Then the instruction strategy \( A(\text{zero})^*_q \) is as depicted in the following diagram:

\[
\begin{array}{ccc}
\mathcal{G}(M|\Rightarrow N)|_0 & \& \mathcal{G}(M|\Rightarrow N)|_1 & \& \mathcal{G}(M|\Rightarrow N)|_0 \\
\Rightarrow & \Rightarrow & \Rightarrow
\end{array}
\]

Clearly, \( \text{st}(A(\text{zero})) = \text{zero} \).

Next, let us consider the successor strategy

\( \text{success} \overset{df}{=} \text{pref}(\{[q_1]|p_0)0^\ast([\bullet]|q_0)|0^\ast|n^\ast[\bullet]|p_1]|n \in \mathbb{N})^\text{even} : [N_0]|e| \Rightarrow [N_1]. \)

We give an algorithm \( A(\text{success}) \) for success by defining \( \mathcal{A}_A(\text{success})(m) \overset{df}{=} \begin{cases} \top & \text{if } m = q_1; \mathcal{A}_A(\text{success}) \overset{df}{=} \{q_1\}, \\
\bot & \text{otherwise, } \mathcal{A}_A(\text{success}) \overset{df}{=} \{q_1\}, \end{cases} \)

\(|A(\text{success})|_q \overset{df}{=} 5, \quad \text{and}

\( A(\text{success})|_q : [q_N \Rightarrow N]|_3 \mapsto [q_N \Rightarrow N]|_2 \mapsto [q_N \Rightarrow N]|_3[q_N \Rightarrow N]|_2[q_N \Rightarrow N]|_0 \mapsto [q_0]|_0 | \\
[q_N \Rightarrow N]|_3[q_N \Rightarrow N]|_2[q_N \Rightarrow N]|_0[x]|_0 \mapsto [q_0]|_0 | \\
[q_N \Rightarrow N]|_3[q_N \Rightarrow N]|_2[q_N \Rightarrow N]|_0[y]|_0 \mapsto [p_1]|_3 | \\
[q_T]|_3 \mapsto [q_N \Rightarrow N]|_2[q_N \Rightarrow N]|_0 \mapsto [q_T]|_3[q_N \Rightarrow N]|_2[q_N \Rightarrow N]|_0 \mapsto [q_T]|_3 | \\
[q_N \Rightarrow N]|_3[q_N \Rightarrow N]|_2[q_N \Rightarrow N]|_0 \mapsto [q_T]|_3[q_T]|_1[q_T]|_3[q_T]|_3 \mapsto [\checkmark]|_3 | \\
[q_T]|_3[q_N \Rightarrow N]|_2[q_N \Rightarrow N]|_0 \mapsto [q_T]|_3[q_T]|_1[q_T]|_3[q_T]|_3 \mapsto [\checkmark]|_3 | \\
[q_T]|_3[q_N \Rightarrow N]|_2[q_N \Rightarrow N]|_0 \mapsto [q_T]|_3[q_T]|_1[q_T]|_3[q_T]|_3 \mapsto [\checkmark]|_3 |
\]

where \( x \in \{\square, \bullet\} \) \( y \in \{\bullet, \cdot\} \). Consequently, \( A(\text{success})|_q^* \) is as depicted in the following:

\[
\begin{array}{ccc}
\mathcal{G}(M|\Rightarrow N)|_0 & \& \mathcal{G}(M|\Rightarrow N)|_1 & \& \mathcal{G}(M|\Rightarrow N)|_2 \\
\Rightarrow & \Rightarrow & \Rightarrow
\end{array}
\]

\[ [q_N \Rightarrow N]|_0 | \\
[q_1]|_2 | \\
[q_0]|_3 \]
We clearly have \( \text{st}(A(\text{succ})) = \text{succ} \), which establishes the effectivity of \( \text{succ} \).

**Example 3.1.8.** Consider the fixed-point strategy \( \text{fix}_A : ([A_{00}]_{(e)_{[\varepsilon]}_{[\varepsilon]}_{[f]} \Rightarrow [A_{10}]_{(e)_{[\varepsilon]}}_{[f]} \Rightarrow [A_1]_{[f]}} \) for each game \( A \) that interprets the fixed-point combinator \( \text{fix}_A \) in PCF [AJM00, HO00, McC98]. Roughly, \( \text{fix}_A \) computes as follows (for its detailed description, see [Hyl97, HO00]):

1. After the first O-move \([a_1]_{[\varepsilon]}\), \( \text{fix}_A \) copies it and makes the second move \([a_{10}]_{[\varepsilon]}_{[\varepsilon]}_{[f]}\), where note that the first move must have the empty outer tag \( \varepsilon \) as \( A \) is finitely well-opened.
2. If Opponent initiates a new thread \([a'_0]|(e')|(e)|f\) in the inner implication, then \(\text{fix}_A\) copies it and launches a new thread in the outer implication by \([a'_0]|(e')|(e)|f\).

3. If Opponent makes a move \([a'_0]|(e')|(e)|f\) (resp. \([a''_0]|(e'')|(e'')|f\), \([a''_0]|(e'')|(e'')|f\)) in an existing thread, then \(\text{fix}_A\) copies it and makes the next move \([a''_{10}](e'')|(e'')|f\) (resp. \([a''_{10}](e'')|(e'')|f\), \([a''_{10}](e'')|(e'')|f\)) in the “dual thread” (to which the third last move belongs).

Clearly, \(\text{fix}_A\) is not finitary for the calculation of outer tags. It is, however, effective for any game \(A\), which is perhaps surprising to many readers. Here, let us just informally describe an algorithm \(\text{Afix}_A\) that realizes \(\text{fix}_A\) (see Section 3.2 for the detailed treatment):

- \(\mathcal{A}_{\text{Afix}_A}(m) = \top\) iff \([m]\) is initial, and \(\mathcal{A}_{\text{Afix}_A} = \{ m \in \pi_1(M\langle A \Rightarrow A \rangle) | \top (A \Rightarrow A) = \top [m] \} \).
  - If the rightmost component of the input strategy for \(\mathcal{A}_{\text{Afix}_A}\) is of the form \([(a_1)|f]\), then \(\mathcal{A}_{\text{Afix}_A}\) calculates the next move \([a_{11}]|f\) once and for all for the internal element and “digit-by-digit” for the outer tag.
  - If the rightmost component is of the form \([(a_0)|f]\), then \(\mathcal{A}_{\text{Afix}_A}\) recognizes it by investigating the third rightmost component, and calculates the next move \([a_1]|f\) once and for all for the internal element and “digit-by-digit” for the outer tag.
  - If the rightmost component is of the form \([(a_0)|(e')|(e)|f]\), then \(\mathcal{A}_{\text{Afix}_A}\) calculates the next move \([a_{00}](e')|(e)|f\) in a similar manner to the above case but with the help of m-views for the outer tag; see Section 3.2 for the details.

- If the rightmost component is of the form \([(a_{10})|(e')|(e)|f]\), then \(\mathcal{A}_{\text{Afix}_A}\) calculates the next move \([a_1]|f\) in a similar manner to the first case with the help of m-views for the outer tag (n.b. the justifier may not be the last or third last move in the P-view, but in that case it is the opening move \([n]\)); see Section 3.2 for the details.

- **Theorem 3.1.9 (Constructions on effective strategies).** Consistent and effective strategies are closed under tensor \(\otimes\), pairing \(\langle - , \rangle\), promotion \(\langle - \rangle\) and concatenation \(\hat{\circ}\).

  **Proof.** The preservation of consistency is straightforward as in [McC98]. We first show that tensor \(\otimes\) preserves effectiveness of strategies. Let \(\sigma : [A_0]e \rightarrow [C_1]e, \tau : [B_0]f \rightarrow [D_1]f\) be effective strategies with algorithms \(A(\sigma), A(\tau)\) realizing \(\sigma, \tau\), respectively. We have to construct an algorithm \(\tilde{A}(\sigma \otimes \tau)\) such that \(\tilde{A}(\sigma \otimes \tau) = \sigma \otimes \tau : [A_0]e \otimes [B_0]f \rightarrow [C_1]e \otimes [D_1]f\). Define the set \(\mathcal{A}_{\sigma \otimes \tau}\) of states and the query \(\mathcal{Q}_{\sigma \otimes \tau} : \pi_1(M_{A\otimes B \rightarrow C \otimes D}) \rightarrow \{\top, \bot\}\) by:

\[
\mathcal{A}_{\sigma \otimes \tau}(m) = \mathcal{A}_{\sigma}(m) \wedge \mathcal{A}_{\tau}(m)
\]

\[
\mathcal{Q}_{\sigma \otimes \tau}(m) = \mathcal{Q}_{\sigma}(m) \wedge \mathcal{Q}_{\tau}(m)
\]

Note that \(\mathcal{Q}_{\sigma \otimes \tau}\) clearly satisfies the required condition, i.e., it outputs \(\top\) if the input is initial, and if it outputs \(\bot\), then the input is initial or internal. Now, construct the finite partial functions \(\tilde{A}(\sigma \otimes \tau)_{m_0}^{n_0} m_{n_0}^{k_0} \ldots m_{n_0}^{k_0} \ldots m_{n_1}^{k_1} \ldots m_{n_1}^{k_1}\) from \(A(\sigma)_{m_0}^{k_0} m_{n_0}^{k_0} \ldots m_{n_0}^{k_0} \ldots m_{n_1}^{k_1} \ldots m_{n_1}^{k_1}\) simply by changing symbols of the form \(m_i\) into \(m_{n_i}\) (including ones for tags) respectively in their (finite) tables. Since P-views of \(\sigma\) and \(\tau\) never interact to each other in \(\sigma \otimes \tau\) (which is shown by induction on the length of positions), it is straightforward to see that \(\tilde{A}(A(\sigma \otimes \tau)) = A(\sigma \otimes \tau)\).
\[ \sigma \otimes \tau \text{ holds. Intuitively, } A(\sigma \otimes \tau) \text{ sees the new digit (0 or 1) of the current state } s \in \mathcal{F}_{A(\sigma \otimes \tau)} \] and decides \( A(\sigma) \text{ or } A(\tau) \) to apply (n.b. \( \mathcal{D}_{A(\sigma \otimes \tau)} \) "tracks" every initial move, and so a possible state must be non-empty in the non-trivial case\(^4\) and so it indicates the component game "at work"). Note that tags are also distinguished in this manner as each component game uses a distinguished copy of the symbols \( |, \tau, \{, \} \), and we distinguish them by 0, 1 digits.

Next, consider the pairing \((\phi, \psi) : L \times R \) of effective strategies \( \phi : L, \psi : R \) such that \( \mathcal{H}^a(L) = C \iff A, \mathcal{H}^a(R) = C \iff B \) for some static games \( A, B, C \). Let \( A(\phi), A(\psi) \) be algorithms realizing \( \phi, \psi \), respectively. Note that \( L \times R \) is the generalized pairing defined in \([YA10]\); roughly, it is the usual pairing but moves in \( C \) and decides \( \sigma \) digits lie on the righthand side, and inner tags of moves in \( A \) with an algorithm in \( A \) way that if \( P \)-moves \( J \in A \) decide the states and the query by:

\[ \mathcal{J}_{A(1)\kappa} \equiv \{ n_{j_1}^{(i)} \ldots n_{j_k}^{(1)} (m_{i_k}^{(0)} \ldots m_{i_0})^{(1)} | n_{j_1}^{(i)} \ldots n_{j_k}^{(1)} \in \mathcal{J}_{A(i)} \} \]

\[ \mathcal{D}_{A(1)\kappa} : m_{i_0} \mapsto \mathcal{A}_{A(i)}(m_{i_0}) | n_{j_1} \mapsto \mathcal{A}_{A(k)}(n_{j_1}). \]

Now, define the finite partial function \( A(\iota \kappa) n_{j_1}^{(i)} \ldots n_{j_k}^{(1)} (m_{i_k}^{(0)} \ldots m_{i_0})^{(1)} \) as \( A(k) n_{j_1}^{(i)} \ldots n_{j_k}^{(1)} \) if \( k = 0 \), and \( A(i) m_{i_k}^{(0)} \ldots m_{i_0}^{(1)} \) otherwise, where we again insert additional bits 0, 1 on the righthand side of internal tags of symbols in the table. Note that \( P \)-views in \( \iota \kappa \) are those in \( \iota \) followed by those in \( \kappa \); therefore it is straightforward to see that \( \text{st}(A(\iota \kappa)) = \iota \kappa \) holds.

Finally, let \( \varphi^\dagger : \{!A_0[\varphi]^{\dagger} \mapsto [B_1]^{\dagger} \} \) be the promotion of a strategy \( \varphi : \{!A_0[\varphi]^{\dagger} \mapsto [B_1]^{\dagger} \} \) with an algorithm \( A(\varphi) \) that realizes \( \varphi \). We define \( \mathcal{J}_{A(\varphi^\dagger)} \equiv \mathcal{J}_{A(\varphi)} \) and \( \mathcal{D}_{A(\varphi^\dagger)} \equiv \mathcal{D}_{A(\varphi)} \). Then roughly, the partial function \( A(\varphi^\dagger)_{m} \) for each \( m \in \mathcal{J}_{A(\varphi^\dagger)} \) is obtained from \( A(\varphi)_{m} \) in such a way that if \( P \)-moves \( [a_0]^{\dagger} \mapsto [b_1]^{\dagger} \) occur in a play for \( \varphi \), and the corresponding play for \( \varphi^\dagger \) begins with an initial move \([b_1]_{[a_0]^{\dagger}}\), then \( \varphi^\dagger \) makes the corresponding moves \([a_0]^{\dagger} \mapsto [b_1]^{\dagger} \mapsto [e']^{\dagger} \) in that play. This is certainly possible by modifying the manipulation of outer tags by \( A(\varphi)_{m} \) appropriately with the help of m-views as follows:

1. The calculation of the next internal element by \( A(\varphi^\dagger)_{m} \) is the same as \( A(\varphi)_{m} \) since \( A(\varphi) \) is assumed to be standard. Below, we focus on the calculation of outer tags.
2. Duplicate the input/output pairs in \( A(\varphi)_{m} \) involved in the calculation of the next internal element but replace the opening move \([q_{A \leftarrow b}^{[a_0]^{\dagger}}] \) and the last moves \([m_3] \) by \([q_T^{[a_0]^{\dagger}}] \) and \([q_{A \leftarrow b}] \), respectively. Also, we "postpone", by m-views, \( A(\varphi^\dagger)_{m} \)’s calculation of the next outer tag until the additional symbol \( [e']^{\dagger} \) has been read off. Since \( A(\varphi^\dagger)_{m} \) sees whether the opening move is \([q_{A \leftarrow b}] \) or \([q_{A \leftarrow b}] \), i.e., its input includes an opening move, the newly added computations will never be confused with the old ones. In this manner, \( A(\varphi^\dagger)_{m} \) learns \( !A \) or \( !B \) the last and the next moves in the P-view respectively belong to.
3. If the last and the next moves in the P-view both belong to \( !A \) (resp. \( !B \)), then their outer tags are of the form \([e']^{\dagger} \mapsto [e]^{\dagger} \mapsto [f]^{\dagger} \) (resp. \([e']^{\dagger} \mapsto [e]^{\dagger} \mapsto [f]^{\dagger} \)).

\(^4\)I.e., when the underlying game is not the terminal game \( I \).
We do not give a formal description of \( A(\varphi) \)'s corresponding computation is standard and maps \( \langle (e')\sharp(e)\rangle \sharp \hat{f} \) (resp. \( \langle (e')\sharp f \) to \( \langle (e')\sharp(e)\rangle \sharp \hat{f} \) (resp. \( \langle (e')\sharp \hat{f} \) whatever \( e' \) is (roughly it first "copy-cats" \( \langle (e')\sharp(e)\rangle \sharp \hat{f} \)) and then the m-view at this point tells it to simulate the computation \( \langle e\rangle \sharp \hat{f} \mapsto \langle \hat{e}\rangle \sharp \hat{f} \) (resp. \( \hat{f} \mapsto \hat{f} \)), inserting another ) between ) and \( \sharp \).

4. If the last and the next moves belong to \( !B \) and \( !A \), respectively, then their outer tags are of the form \( (\langle (e')\sharp(e)\rangle \sharp \hat{f} \) (resp. \( \langle (e')\sharp \hat{f} \) by \( \varphi \)) \). Note that they correspond to moves with the same internal elements and the outer tags \( \langle e\rangle \sharp \hat{f} \), respectively, in \( A(\varphi) \). When \( A(\varphi) \) continues, it first adds the symbol (, and then "copy-cats" \( \langle (e')\sharp \hat{f} \). At this point, the m-view tells \( A(\varphi) \) to simulate the calculation of \( \langle e\rangle \sharp \hat{f} \) of \( A(\varphi) \), inserting another ) between ) and \( \sharp \).

We do not give a formal description of \( A(\varphi) \) as it would be much more involved and hard to read; however, the above description should suffice to indicate how we may construct it.

\begin{itemize}
  \item Example 3.1.10. Consider the tensor \( \text{succ} \otimes \text{pred} : [N_{00}]_{\langle e\rangle \sharp} \otimes [N_{10}]_{\langle e'\rangle \sharp} \rightarrow [N_{01}] \otimes [N_{11}] \). A typical play by \( \text{succ} \otimes \text{pred} \) is as follows:

\[
\begin{array}{ccc}
[N_{00}]_{\langle e\rangle \sharp} & \otimes & [N_{10}]_{\langle e'\rangle \sharp} & \text{succ \otimes pred} & [N_{01}] & \otimes & [N_{11}] \\
\hline
[q_{10}]_{\langle e\rangle \sharp} & \otimes & [q_{10}]_{\langle e'\rangle \sharp} & \rightarrow & [q_{01}] \\
[p_{10}]_{\langle e\rangle \sharp} & \otimes & [p_{10}]_{\langle e'\rangle \sharp} & \rightarrow & [p_{11}] \\
[p_{00}]_{\langle e\rangle \sharp} & \otimes & [p_{00}]_{\langle e'\rangle \sharp} & \rightarrow & [p_{01}] \\
\end{array}
\]

Applying the construction described in the proof of Theorem 3.1.9, we construct an algorithm \( A(\text{succ} \otimes \text{pred}) \) by \( A(\text{succ} \otimes \text{pred}) = \{q_{01}, q_{11}\} \), \( \mathcal{P}_{A(\text{succ} \otimes \text{pred})}(m) = \begin{cases} \top & \text{if } m = q_{01} \lor m = q_{11}, \\ \bot & \text{otherwise} \end{cases} \)

and \( A(\text{succ} \otimes \text{pred})_{q_{01}} \) (resp. \( A(\text{succ} \otimes \text{pred})_{q_{11}} \)) is obtained from \( A(\text{succ})_{q_{01}} \) (resp. \( A(\text{pred})_{q_{11}} \)) by replacing symbols \( m_i \) with \( m_{0i} \) (resp. \( m_{1i} \)). It is easy to see that \( A(\text{succ} \otimes \text{pred}) \) achieves the computation in the above diagram, and moreover \( \text{st}(A(\text{succ} \otimes \text{pred})) = \text{succ} \otimes \text{pred} \) holds.

\item Example 3.1.11. Consider the pairing \( \langle \text{succ}, \text{pred} \rangle : [N_{00}]_{\langle e\rangle \sharp} \rightarrow [N_{10}] \& [N_{11}] \), where note that the 0, 1 digits in the codomain differ from those in the case of \( \otimes \). Its typical plays are as follows:

\[
\begin{array}{ccc}
[N_{00}]_{\langle e\rangle \sharp} & \otimes & [N_{10}] \& [N_{11}] \\
\hline
[q_{10}]_{\langle e\rangle \sharp} & \otimes & [q_{10}] \& [q_{11}] \\
[p_{10}]_{\langle e\rangle \sharp} & \otimes & [p_{10}] \& [p_{11}] \\
[p_{00}]_{\langle e\rangle \sharp} & \otimes & [p_{00}] \& [p_{01}] \\
\end{array}
\]

Again, as described in the proof of Theorem 3.1.9, we construct an algorithm \( A(\langle \text{succ}, \text{pred} \rangle) \) by

\[
\begin{array}{l}
A(\langle \text{succ}, \text{pred} \rangle) = \{q_{10}, q_{11}\} \), \mathcal{P}_{A(\langle \text{succ}, \text{pred} \rangle)}(m) = \begin{cases} \top & \text{if } m = q_{10} \lor m = q_{11}, \\ \bot & \text{otherwise} \end{cases} \)
\end{array}
\]
Let us apply the construction in the proof of Theorem 3.1.9. The set \( A((\text{succ}, \text{pred}))_{q_1} \) (resp. \( A((\text{pred})_{q_1}) \)) by replacing symbols \( m_1 \) with \( m_{1,0} \) (resp. \( m_1,1 \)). Then \( A((\text{succ}, \text{pred})) \) clearly achieves the computation in the above diagram, and furthermore \( \text{st}(A((\text{succ}, \text{pred}))) = (\text{succ}, \text{pred}) \) holds.

**Example 3.1.12.** Consider the promotion \( \text{succ}^1 : [\![N_0]_{(e)}]_{\sharp} \rightarrow [\![N_1]_{(e')}\sharp] \). Its typical play is as depicted in the following diagram:

| \[\![N_0]_{(e)}\sharp\] | \(\text{succ}^1\) | \[\![N_1]_{(e')}\sharp\] |
|----------------------|-----------------|----------------------|
| \[q_0\] \(\langle e'\rangle\sharp\) | \[q_1\] \(\langle e'\rangle\sharp\) |
| \(\bullet_0\) \(\langle e'\rangle\sharp\) | \[\bullet_1\] \(\langle e'\rangle\sharp\) |
| ... | ... |
| \[q_0\] \(\langle e'\rangle\sharp\) | \[q_1\] \(\langle e'\rangle\sharp\) |
| \[q_0\] \(\langle e'\rangle\sharp\) | \[\bullet_1\] \(\langle e'\rangle\sharp\) |
| \[\bullet_0\] \(\langle e'\rangle\sharp\) | \[\bullet_1\] \(\langle e'\rangle\sharp\) |

Let us apply the construction in the proof of Theorem 3.1.9. The set \( \mathcal{F}_{A((\text{succ})} \) of states and the query \( \mathcal{P}_{\mathcal{A}(\text{succ})} \) are the same as those of \( A(\text{succ}) \). For the computation of the outer tag of the next move (i.e., when the opening move is \( [q_T]_3 \) in \( G(M_{N \Rightarrow N}) \) in \( G(M_{N \Rightarrow N}) \)), recall, e.g., how \( A((\text{succ})_{q_1}^*) \) computes the second move from the opening move in \( N \Rightarrow N \):

\[
\begin{align*}
\mathcal{G}(M_{N \Rightarrow N})_0 & \& \mathcal{G}(M_{N \Rightarrow N})_1 & \& \mathcal{G}(M_{N \Rightarrow N})_2 \xrightarrow{A(\text{succ})_{q_1}^*} \mathcal{G}(M_{N \Rightarrow N})_3 \\
[q_N \Rightarrow N]_2 & \& [q_1]_2 & \& [q_0]_3 \\
[q_N \Rightarrow N]_0 & \& [q_1]_2 & \& [q_T]_3 \\
[q_N \Rightarrow N]_0 & \& [q_1]_2 & \& [\sqrt{y}]_3
\end{align*}
\]
Let us see how $A(succ^\dagger)_{q_i}$ computes the outer tag of the next move when the last move is an opening $[q_1]_2$ and the next move is $[q_0](\langle 2 \rangle \sharp)$ in $!N \to !N$:

| $G(M_{N \Rightarrow N})_0$ & $G(M_{N \Rightarrow N})_1$ & $G(M_{N \Rightarrow N})_2$ & $A(succ^\dagger)_{q_i}$ & $G(M_{N \Rightarrow N})_3$ |
|-----------------|-----------------|-----------------|-----------------|-----------------|
| $[q_N \Rightarrow N]_2$ | $[q_1]_2$ | $[q_N \Rightarrow N]_2$ | $[q_1]_2$ | $[q_T]_3$ |
| $[q_T]_2$ | $[\sqcap]_0$ | $[q_T]_2$ | $[\sqcap]_0$ | $[q_T]_3$ |
| $[q_T]_2$ | $[\sqcap]_2$ | $[q_T]_2$ | $[\sqcap]_2$ | $[q_T]_3$ |
| $[q_T]_2$ | $[\sqcup]_2$ | $[q_T]_2$ | $[\sqcup]_2$ | $[q_T]_3$ |
| $[q_T]_2$ | $[\sqcup]_2$ | $[q_T]_2$ | $[\sqcup]_2$ | $[q_T]_3$ |
| $[q_N \Rightarrow N]_0$ | $[q_1]_2$ | $[q_N \Rightarrow N]_0$ | $[q_1]_2$ | $[q_T]_3$ |

It should be clear how $A(succ^\dagger)_{q_i}$ calculates the outer tag of the next move in other cases. In this way, $st(A(succ^\dagger)) = succ^\dagger$ in fact holds.
Example 3.1.13. Consider the concatenation $\text{succ}^\dagger \downarrow \text{pred} : ([!N_0]_{e^1} \dashv \circ [!N_1]_{e^2}) \downarrow ([!N_0]_{e^1} \dashv \circ [N_{11}])$. Its typical play is as follows:

$$
\begin{array}{ccc}
[!N_0]_{e^1} & \downarrow \text{succ}^\dagger & [!N_1]_{e^2} \\
[q_0] & \text{pred} & [q_11] \\
[p_0] & \text{succ} & [p_{11}]
\end{array}
$$

Applying the recipe in the proof of Theorem 3.1.9 we define an algorithm $A(\text{succ}^\dagger \downarrow \text{pred})$ as follows. Define $A(\text{succ}^\dagger \downarrow \text{pred}) \equiv \{ q_{10}, q_{11} \}$, $\mathcal{D}_A(m) \equiv \begin{cases} \top & \text{if } m = q_{10} \lor m = q_{11} \text{, and} \\ \bot & \text{otherwise} \end{cases}$.

$A(\text{succ}^\dagger \downarrow \text{pred})_{q_1}$ (resp. $A(\text{pred}^\dagger \downarrow \text{pred})_{q_1}$) is obtained from $A(\text{succ}^\dagger)_{q_1}$ (resp. $A(\text{pred})_{q_1}$) just by changing symbols $m_i$ into $m_{i0}$ (resp. $m_{i1}$) in its finite table. It is then clear that $A(\text{succ}^\dagger \downarrow \text{pred})$ achieves the computation in the above diagram, and $\text{st}(A(\text{succ}^\dagger \downarrow \text{pred})) = \text{succ}^\dagger \downarrow \text{pred}$ holds.

3.2 Examples of atomic strategies

This section presents various examples of consistent and effective “atomic” strategies. Let us remark beforehand that these strategies except the fixed-point strategies fix are representable by finite view functions; thus, we need the notion of effective strategies only for promotion and fix.

Remark. When describing strategies below, we usually keep justifiers implicit for brevity as they are always obvious in our examples.

Example 3.2.1. Similarly to zero and succ, we may give an algorithm $A(\text{pred})$ for the predecessor strategy $\text{pred} : [N_0]_{e^1} \Rightarrow [N_1]$ defined by:

$$
\begin{align*}
\text{pred} & \equiv \text{pref}\{ \{[q_1][q_0]_{01}[n_0]|01\} | 01 \} \\
& \cup \{/[q_1][q_0]_{01}[p_0]|n_1\}\}^{\text{even}}
\end{align*}
$$

whose states and query are the same as those for succ. At this point, it suffices to show a similar diagram for $A(\text{pred})_{q_1}$. As it is clear that there is a finite table $A(\text{pred})_{q_1}$ achieving it:

$$
\begin{array}{ccc}
\mathcal{G}(M_{N \Rightarrow N})_1 & \mathcal{G}(M_{N \Rightarrow N})_2 & \mathcal{G}(M_{N \Rightarrow N})_3 \\
[q_{N \Rightarrow N}]_2 & [q_1]_2 ([p_0]_2) & [q_{03}] ([p_1]_3)
\end{array}
$$

we may show that the dereliction
\[\Delta \vdash \text{dereliction}\]
Also, \[\Delta \vdash \text{dereliction}\]
Example 3.2.3. Consider the case strategy \(\text{case}_A : [A_0](e^r)\sharp_f \Rightarrow [A_0](e^r)\sharp_f \Rightarrow [2_011](e)\sharp \Rightarrow [A_{111}]_f\) on each game \(A\) defined by
\[
\text{case}_A \overset{\text{def}}{=} \text{pref}(\{[a_{111}][q_{011}][T_{011}][q_0][a_0][0]_2.s \in P_{A \Rightarrow A \Rightarrow 2 \Rightarrow A}[a_{111}][a_0][0]_2.s \in \text{der}_A^0\})
\]
\[
\cup \{[a_{111}][q_{011}][T_{011}][q_0][a_0][0]_2.t \in P_{A \Rightarrow A \Rightarrow 2 \Rightarrow A}[a_{111}][a_0][0]_2.t \in \text{der}_A^0\}\}
\]
where \(\text{der}_A^0 : [A_0](e^r)\sharp_f \Rightarrow [A_{111}]_f, \text{der}_A : [A_0](e^r)\sharp_f \Rightarrow [A_{111}]_f\) are the same as the usual dereliction \(\text{der}_A : [A_0](e^r)\sharp_f \Rightarrow [A_{111}]_f\). Since this strategy distinguishes different copies of symbols \(\{,\},\), we explicitly write subscripts \(\alpha \in \{0,1\}^*\) on them. We give an algorithm \(\text{A}(\text{case}_A)\) that realizes \(\text{case}_A\) whose states and query are the same as \(\text{A}(\text{cp}_A)\), and for all \(m \in \text{\textsc{I}(\text{case}_A)}\) the instruction strategy \(\text{A}(\text{case}_A)_m\) is as follows (again, since we have described \(\text{cp}_A\), we skip formally writing down \(\text{A}(\text{case}_A)_m\) as it should be clear):
\[
\text{G}([A_0 \Rightarrow A \Rightarrow 2 \Rightarrow A]_0) \& \text{G}([A_0 \Rightarrow A \Rightarrow 2 \Rightarrow A]_1) \& \text{G}([A_0 \Rightarrow A \Rightarrow 2 \Rightarrow A]_2) \Rightarrow \text{G}([A_0 \Rightarrow A \Rightarrow 2 \Rightarrow A]_3)
\]
\[

\end{align*}
\]
Clear at this point): the following diagrams (again, we omit the formal description of $A$ case standard, and $G$ (case $A$)) = case $A$, and so case $A$ is effective. And again, $A$ (case $A$) is clearly standard, and case $A$ is trivially consistent.

Example 3.2.4. Consider the ifzero strategy zero? : $[N_0](e_0) ⇒ [2]$ defined by zero? $df ≡$ pref($(q_1)[q_0][0][0][0][1],[q_1][q_0][0][0][0][1]$, $e_0) =$ even, which is trivially consistent. Let us give an algorithm $A$ (zero?) that realizes zero? as follows. Define $D_{A(zero?)}(m) df ≡ \begin{cases} \top & \text{if } m = q_1 \\ \bot & \text{otherwise} \end{cases}$ and the instruction strategy $A$ (zero?) is as depicted in the following diagrams (again, we omit the formal description of $A$ (zero?) as it should be clear at this point):
We clearly have $\text{st}(A(\text{zero}')) = \text{zero}'$, and $A(\text{zero}')$ is standard.

Example 3.2.5. Consider the fixed-point strategy $\text{fix}_A : ([A_{00}]_1 [e']_1 [e]_1 f) \Rightarrow [A_{01}]_1 [e']_1 f \Rightarrow [A_1]_1 f$ for each game $A$ [AJM00, HO00, McC98]. We have already described $\text{fix}_A$ informally; here we give a more detailed account, but again, it should suffice to just give diagrams for $A(\text{fix}_A)^m_m$ ($m \in \mathcal{F}_{\text{fix}_A}$):
\[ G(M_{A \Rightarrow A \Rightarrow A})_0 \quad \& \quad G(M_{A \Rightarrow A \Rightarrow A})_1 \quad \& \quad G(M_{A \Rightarrow A \Rightarrow A})_2 \quad \Rightarrow \quad G(M_{A \Rightarrow A \Rightarrow A})_3 \]

\[ \begin{aligned}
[q_{A \Rightarrow A \Rightarrow A}]_2 \\
[q_{A \Rightarrow A \Rightarrow A}]_2
\end{aligned} \]

\[ \begin{aligned}
[a_{00}]_2 \\
[k]_2 \\
\text{[\text{\texttt{e}}]}_2 \\
\vdots \\
[k]_2 \\
[k]_2 \\
\end{aligned} \]

\[ \begin{aligned}
\text{[\text{\texttt{e}}]}_2 \\
\text{[\text{\texttt{e}}]}_2 \\
\text{[\text{\texttt{e}}]}_2 \\
\vdots \\
\text{[\text{\texttt{e}}]}_2 \\
\text{[\text{\texttt{e}}]}_2 \\
\end{aligned} \]

\[ \begin{aligned}
\text{[\text{\texttt{e}}]}_2 \\
\text{[\text{\texttt{e}}]}_2 \\
\text{[\text{\texttt{e}}]}_2 \\
\vdots \\
\text{[\text{\texttt{e}}]}_2 \\
\text{[\text{\texttt{e}}]}_2 \\
\end{aligned} \]

\[ \begin{aligned}
\text{[\text{\texttt{e}}]}_2 \\
\text{[\text{\texttt{e}}]}_2 \\
\text{[\text{\texttt{e}}]}_2 \\
\vdots \\
\text{[\text{\texttt{e}}]}_2 \\
\text{[\text{\texttt{e}}]}_2 \\
\end{aligned} \]

\[ \begin{aligned}
\text{[\text{\texttt{e}}]}_2 \\
\text{[\text{\texttt{e}}]}_2 \\
\text{[\text{\texttt{e}}]}_2 \\
\vdots \\
\text{[\text{\texttt{e}}]}_2 \\
\text{[\text{\texttt{e}}]}_2 \\
\end{aligned} \]

\[ \begin{aligned}
\text{[\text{\texttt{e}}]}_2 \\
\text{[\text{\texttt{e}}]}_2 \\
\text{[\text{\texttt{e}}]}_2 \\
\vdots \\
\text{[\text{\texttt{e}}]}_2 \\
\text{[\text{\texttt{e}}]}_2 \\
\end{aligned} \]
where \( @i \) in the diagrams indicates the pairs (\( i \)) of mates, i.e., (\( i \)) and (\( j \)) with the same \( i \) form such a pair. Note that with \( m \)-views, there is an obvious finite table \( A(\text{fix}_A)_m \) that implements the instruction strategy \( A(\text{fix}_A)_m \). It is then not hard to see that \( \text{st}(A(\text{fix}_A)) = \text{fix}_A \) holds, showing that \( \text{fix}_A \) is effective. Also, it is easy to see that \( \text{fix}_A \) is consistent, and \( A(\text{fix}_A) \) is standard.

### 3.3 Turing completeness

In the previous sections, we have seen that every “atomic” strategy that is definable in the language PCF \(^{[AM99]}\) is consistent and realized by a standard algorithm, and constructions on strategies preserve this property. From this, our main theorem immediately follows:

> **Theorem 3.3.1** (Main theorem). Every (static) strategy \( \sigma : A \) definable in PCF \(^{[AM99]}\) has a consistent and effective strategy \( \phi_\sigma : D_A \) that satisfies \( \mathcal{H}^\omega(\phi_\sigma) = \sigma \land \mathcal{H}^\omega(D_A) \subseteq A \) up to tags.

**Proof.** First, see \(^{[AM99]}\) for the strategies definable in the language PCF, (and \(^{[YA16]}\) for the (implicitly) underlying bicategory \( \mathcal{DG} \) of dynamic games and strategies though it is not strictly necessary). We have already shown in the previous sections that the “atomic” strategies such as \( \text{der}_A, \text{succ}, \text{pred}, \text{zero?} \), \( \text{case}_A, \text{fix}_A \) are all consistent and effective, in particular realized by standard algorithms. Note that projections are derelictions up to internal tags, and so they are clearly consistent and effective. Similarly, the currying \( \Lambda \) and uncurrying \( \Lambda^{-1} \) operations are just to modify internal tags; thus, they clearly preserve consistency and effectivity (in particular realizability by standard algorithms) of strategies. In particular, the evaluation strategies \( ev_{A,B} : (A \Rightarrow B) \& A \rightarrow B \) are obtained from derelictions by uncurrying, and so they are consistent and effective as well.

Now, note that we may enumerate all the strategies definable in PCF by the following inductive construction of a set \( S \) of strategies:

1. \( \sigma \in S \) if \( \sigma : A \) is “atomic”
2. \( \Lambda(\sigma) \in S \) if \( \sigma \in S \) such that \( \sigma : G \) with \( \mathcal{H}^\omega(G) \subseteq A \& B \rightarrow C \) for some games \( G, A, B, C \)
3. \( \langle \varphi, \psi \rangle \in S \) if \( \varphi : L, \psi : R \) with \( \mathcal{H}^\omega(L) \subseteq C \rightarrow A, \mathcal{H}^\omega(R) \subseteq C \rightarrow B \) for some games \( L, R, A, B, C \)
4. \( i^1; \kappa \in S \) if \( i, \kappa \in S \) such that \( i : J, \kappa : K \) with \( \mathcal{H}^\omega(J) \subseteq A \rightarrow B, \mathcal{H}^\omega(R) \subseteq B \rightarrow C \) for some games \( J, K, A, B, C \).

We may assign a consistent and effective strategy \( \phi_\sigma \) to each \( \sigma \in S \) as follows: 1. \( \phi_\sigma \overset{\text{df}}{=} \sigma \) if \( \sigma \) is “atomic”; 2. \( \phi_{\Lambda(\sigma)} \overset{\text{df}}{=} \Lambda(\phi_\sigma) \); 3. \( \phi_{\langle \varphi, \psi \rangle} \overset{\text{df}}{=} \langle \phi_\varphi, \phi_\psi \rangle \); 4. \( \phi_{i^1; \kappa} \overset{\text{df}}{=} \phi_i^1 \upharpoonright \phi_\kappa \).

By the above argument and Theorem 3.3.1, \( \phi_\sigma \) is in fact consistent and effective for all \( \sigma \in S \). It remains to show \( \mathcal{H}^\omega(\phi_\sigma) \overset{\text{df}}{=} \sigma \) for all \( \sigma \in S \) (it is similar to show the subgame relation), where \( \overset{\text{df}}{=} \) denotes the equality up to tags. We may show it by induction with basic results in \(^{[YA16]}\):

1. \( \mathcal{H}^\omega(\phi_\sigma) = \mathcal{H}^\omega(\sigma) = \sigma \) if \( \sigma \) is “atomic” since every “atomic” strategy is static
2. \( \mathcal{H}^\omega(\phi_{\Lambda(\sigma)}) = \mathcal{H}^\omega(\Lambda(\phi_\sigma)) = \Lambda(\mathcal{H}^\omega(\phi_\sigma)) \overset{\text{by induction hypothesis}}{=} \Lambda(\sigma) \)
3. \( \mathcal{H}^\omega(\phi_{\langle \varphi, \psi \rangle}) = \mathcal{H}^\omega(\langle \phi_\varphi, \phi_\psi \rangle) = \langle \mathcal{H}^\omega(\phi_\varphi), \mathcal{H}^\omega(\phi_\psi) \rangle \overset{\text{by induction hypothesis}}{=} \langle \varphi, \psi \rangle \)
4. \( \mathcal{H}^\omega(\phi_{i^1; \kappa}) = \mathcal{H}^\omega(\phi_i^1 \upharpoonright \phi_\kappa) = \mathcal{H}^\omega(\phi_i^1); \mathcal{H}^\omega(\phi_\kappa) \overset{\text{by induction hypothesis}}{=} \mathcal{i^1; \kappa} \)

which completes the proof.
Since PCF is Turing complete \cite{Gun92, LN15}, this result particularly implies the following:

\begin{itemize}
  \item \textbf{Corollary 3.3.2} (Turing completeness). Every partial recursive function $f : \mathbb{N}^k \to \mathbb{N}$, where $k \in \mathbb{N}$, has a consistent and effective strategy $\phi_f : D_f$ such that $\mathcal{H}(D_f) \leq N^k \Rightarrow N$ and $f(n) \simeq \mathcal{H}(\langle n_1, n_2, \ldots, n_k \rangle^\dagger \phi_f)$ up to tags for all $(n_1, n_2, \ldots, n_k) \in \mathbb{N}^k$.
\end{itemize}

4 Conclusion and future work

We have presented the first \textit{intrinsic} notion of “effective computability” in game semantics. Due to its \textit{semantic} and \textit{non-inductive} nature, it can be seen as a fundamental investigation of the mathematical notion of “effective computation” beyond the classical computation.

There are many directions for further work; here we only mention some of them. First, we need to analyze the exact computational power of effective strategies, in comparison with other known notion of higher-order computability \cite{LN15}. Also, as an application, the present framework may give an accurate measure for computational complexity \cite{Koz06}. However, the most imminent future work is perhaps, by exploiting the flexibility of game semantics, to enlarge the scope of the present work (i.e., not only the language PCF) in order to establish a mathematical model of various (constructive) logics and programming languages.
