Abstract

17-months old infant with Wiskott-Aldrich syndrome was transplanted with genetically two-locus mismatched unrelated cord blood cells under the conditioning regimen of busulfan, cyclophosphamide and anti-thymocyte globulin. GVHD prophylaxis was cyclosporine (CSP) plus short-term methotrexate with prednisolone (1 mg/kg). Acute and chronic GVHD were not observed during the course. About six years later, he suffered from severe cough and dyspnea with no fever, and diagnosed as late onset non-infectious pulmonary complications (LONIPC). We have to be careful for LONIPC after SCT even in the absence of chronic GVHD for younger children because the sign of insidious obstructive pulmonary symptoms is difficult to monitor. To avoid the unexpected LONIPC, introduction of RIC regimen should be considered for younger children, although it has been reported that RIC regimen may increase the risk for GVHD and graft rejection.

Keywords: Non-infectious pulmonary complication; Chronic GVHD; Allogeneic hematopoietic stem cell transplantation

Introduction

Late onset non-infectious pulmonary complications (LONIPC) consist of major causes of morbidity and mortality after allogeneic hematopoietic stem cell transplantation (allo-HSCT). These include bronchiolitis obliterans (BO), bronchiolitis obliterans with organizing pneumonia (BOOP), and idiopathic pneumonia syndrome (IPS), and usually occur three months after HSCT. According to the literature, the incidence has been reported to be 10-25% [1]. Not well elucidated, it is speculated that allo-immune reactions play a major role in the pathogenesis, because they are closely associated with the presence of chronic GVHD. Concerning to LONIPC among the pediatric patients, few reports are available. Kojima et al have reported as a single institutional experience that the incidence of LONIPC in the pediatric patients was 10.3%, the median onset was 187 days (123-826 days), and it was also related with chronic GVHD as in the cases of adults [2].

Case Report

17-months old infant with Wiskott-Aldrich syndrome was transplanted with genetically two-locus mismatched unrelated cord blood cells. Major clinical symptoms were eczema and thrombocytopenia (<1 × 10^4/μl) and he had no significant infection episodes before SCT. No expression of WASP protein was found in T-lymphocytes, and genetic analysis revealed splicing anomaly due to point mutation in intron2. Conditioning regimen consisted of busulfan (4 mg/kg/day for 4 days), cyclophosphamide (50 mg/kg/day for 4 days) and horse anti-thymocyte globulin (10 mg/kg/day for 4 days), and GVHD prophylaxis was cyclosporine (CSP) plus short-term methotrexate with prednisolone (1 mg/kg). Dose of oral busulfan was determined by the prior test dose and pharmacokinetic analysis. Methotrexate on day 6 and day 11 was omitted because of elevated serum transaminase. Neutrophil engraftment was on day 19, platelet engraftment on day 71 and complete chimerism was determined on day 21.

Because no GVHD was observed, CSP was stopped on day 95, and prednisolone on day 251. He became free of immunoglobulin supplementation one year after CBT. There were no significant infection episodes after CBT.

5 and 1/2 years after CBT, he began to complain of occasional dry cough, which resolved easily under cough remedy. A couple of months later, he suffered from severe cough and dyspnea with no fever. Auscultation revealed fine crackles on both lungs, and his oxygen saturation was 92% in room air. Chest X-ray presented marked consolidation of bronchioles (Figure 1). Under the suspicion of LONIPC, prednisolone (1 mg/kg/day) was started, which ameliorated his symptoms rapidly. Serum soluble IL-2R was slightly elevated to 937 U/ml (normal value: 0-500), and serum KL-6 was 458 U/ml (normal value: 0-500). Involvement of pathogens including RSV, CMV and fungi was excluded from the later examinations. He has been placed on oral prednisolone with clarithromycin (5 mg/kg/day) and fluticasone inhalation (twice daily). Three years later, he has been placed on home oxygen therapy and lung transplantation has been scheduled.

Discussion

Between 2001 and 2011, 72 pediatric patients (7m-22y8m; 7y3m ± 6y8m [mean ± SD]) have received 77 allogeneic stem cell transplantsations in our institute. 9 patients (13.4%) in 67 patients who survived more than 3 months after SCT developed LONIPC (Table 1: observation period; 1155-5145 days). Multivariate analysis revealed myeloablative conditioning regimen and chronic GVHD as significant risk factors of LONIPC (data not shown). Unexpectedly, two patients developed LONIPC more than five years after HSCT and one patient died of respiratory failure 30 months after diagnosis of LONIPC.

As shown in Table 1, LONIPC was closely related with chronic GVHD also in our experience. Unexpectedly, two patients had no

Table 1: Profile of patients who developed LONIPC.

It has been reported that decline of air flow could be a good hall mark of non-infectious pulmonary complication after SCT [4-6]. However, it is difficult to monitor FEV1/FVC for younger children such as this case. Figure 2 showed the growth chart of this patient after SCT. Retrospectively, retardation of weight gain was found before the onset of LONIPC, although it is difficult to determine whether it was an early sign of pulmonary symptoms or not. We have to be careful to check the development of LONIPC after SCT even in the absence of chronic GVHD especially for infants or younger children because the sign of insidious obstructive pulmonary symptoms is difficult to monitor. It has been recently reported that RIC regimen stabilized long-term pulmonary function in adult patients with allogeneic SCT [7]. To avoid the unexpected LONIPC, introduction of RIC regimen should be considered for younger children, although it has been reported that RIC regimen may increase the risk for GVHD, CMV reactivation and graft rejection [8,9].
Figure 2: Growth chart of the patient. Dot bar represents the mean value of height and weight from Japanese national database. During the use of prednisolone, growth of height was sustained. Just before the onset of LONIPC, weight gain was retarded.
