Branched-chain amino acids (BCAAs) and telomere length are biologically associated with healthy aging. However, the association between them and their interaction on frailty remain unclear in humans. Here, a cross-sectional study based on residents from Guangxi longevity county was conducted to investigate the association of serum BCAAs, peripheral leukocyte telomere length (LTL) and frailty. A total of 1,034 subjects aged 20 to 110 years were recruited in the study. The real-time qPCR method and a targeted metabolomics approach based on isotope dilution liquid chromatography tandem mass spectrometry (LC/MS/MS) method were used for measurement of LTL and BCAAs, respectively. A frailty score defined as the proportion of accumulated deficits based on 24 aging-related items was used assess the health status of elderly subjects. First, we found that a higher concentration of BCAAs was significantly associated with longer LTL only in middle-aged subjects, independent of age and BMI (P < 0.05). In the oldest-old subjects, we identified a significantly inverse association between BCAAs and frailty score (P < 0.001), even after adjustment for age and BMI (P < 0.05). Additionally, we recognized a statistically significant synergetic interaction between BCAAs and LTL on frailty score in the oldest-old subjects by the general linear model (P = 0.042), although we did not find any significant association between LTL and frailty score. In summary, our findings suggest a potentially protective effect of circulating BCAAs on LTL and frailty based on the subjects from longevity county in East Asia and indicate a potential synergetic interaction between BCAAs and LTL in healthy aging.

As a major phenotype of aging1, frailty is characterized by increasing vulnerability to external factors, a decreasing the ability to resist stress, and progressive loss of muscle performance2,3. Further, frailty has been reported to be a dominant risk factor for major cardiovascular endpoints and mortality in elderly4. Because frailty seems to be a dynamic process and also potentially reversible4, early recognition and intervention of frailty is important to achieve the goal of healthy aging. At present, the assessment of frailty is based on two methods: phenotypic method and cumulative health deficits method1. Compared to the phenotype approach, the accumulation of deficits approach is a more sensitive predictor for adverse health outcomes due to its finer graded scale and its multidimensionality5 and more suitable to provide a mechanistic understanding of the aging phenomenon6.

Branched-chain amino acids (BCAAs) are essential amino acids for the human, namely, valine (Val), leucine (Leu) and isoleucine (Ile). In addition to being proteogenic amino acids, BCAAs are also signaling molecules7. It was reported that BCAAs catabolism is a conserved regulator of physiological aging8. The mechanistic target of

Peripheral leukocyte telomere length (LTL) is recognized as a biomarker of cellular aging and biological aging and is influenced by many factors (e.g., genetic, epigenetic, lifestyle and environment). Telomere shortening activates p53-mediated cellular growth arrest, senescence and apoptosis and induces metabolic and mitochondrial compromise. It has been reported to be associated not only with chronological age but also age-associated pathologies. Recently, it has been proposed that frailty may lead to premature apoptosis in cells with normal length telomeres. There are also many studies exploring the correlation between telomere length (TL) and frailty in the elderly, but the conclusions are inconsistent, and especially the data for the oldest-old are lacking.

Yongfu County, located in Guangxi Province, has been qualified as a longevity town by the Geriatric Society of China in 2007. Based on the local residents, we have conducted a longitudinal follow-up study for more than 10 years focusing on factors affecting longevity and healthy aging. Although BCAAs and TL are biologically associated with healthy aging, the association between them and their interaction on frailty remain unclear in the elderly, but the conclusions are inconsistent, and especially the data for the oldest-old are lacking.

**Results**

Of the 1,034 included subjects, 478 (46.2%) were men, and 627 (60.6%) are the oldest-old aged from 86 to 110 years old. The mean (standard deviation, SD) concentrations of BCAAs, Val, Leu and Ile were 484.4 (103.8), 232.5 (46.1), 176.0 (45.3) and 75.9 (18.7) μmol/L, respectively. It is observed that the basic characteristics of the oldest-old subjects are significantly different from those of middle-aged subjects (Table 1). Finally, the calculation of frailty score proved to be an effective parameter for evaluating aging-related health status.

**Table 1.** Characteristics of study participants. BMI, body mass index; SBP, Systolic blood pressure; DBP, Diastolic blood pressure; BCAAs, branched-chain amino acids; Val, valine; Leu, leucine; Ile, isoleucine; LTL, leukocyte telomere length. *Data are mean ± SD for continuous variables and n (%) for categorical variables. Overweight was defined as 24 kg/m² ≤ BMI < 28 kg/m². Obesity was defined as 28 kg/m² ≤ BMI.

*Overweight was defined as 24 kg/m² ≤ BMI < 28 kg/m². Obesity was defined as 28 kg/m² ≤ BMI.*
A significantly inverse association between BCAAs and frailty score was found in all the oldest-old subjects ($r = -0.20, P < 0.001$) and both genders ($P < 0.001$). Each one SD increasement in BCAAs, Val, Leu, and Ile were remarkably associated with a reduction of mean frailty score in all the oldest-old subjects (Table 2) and both genders (Table S3). Further stratified analysis was performed due to the association between BCAAs and LTL, indicating that the inverse association of BCAAs with frailty was still established in subjects with long LTL. However, there was no significant association between LTL and frailty score ($P = 0.362$).

**Interaction between serum BCAA and LTL for frailty score.** A significant reduction in mean frailty score was found in the group with high serum BCAAs concentration and long LTL compared with the reference group with low serum BCAAs concentration and short LTL ($P < 0.01$). A statistically significant synergetic interaction between BCAAs, as well as Leu, and LTL on frailty score was recognized in the oldest-old subjects ($P < 0.05$) (Table 3).

**Discussion**
To our knowledge, this is the first population-based study showing that elevated serum BCAAs concentrations are associated with longer LTL in middle-aged subjects and suggesting a potential synergetic interaction between serum BCAAs and LTL for the frailty of the oldest-old subjects.

It is widely accepted that the frailty of elderly subjects is closely related to aging-related skeletal muscle loss22. In addition, defects in mTOR signaling have been found in sarcopenic muscle23. It is also well-known that BCAAs are essential in the maintenance of muscle content and anabolic effects because they improve protein synthesis, and decrease the rate of protein degradation24. In our study, the significant negative association between BCAAs and frailty score was consistent with the other study2. However, the synergetic interaction between BCAAs and LTL for the frailty of the oldest-old has not been reported in other studies.
for the mTORC1 pathway. And previous studies have demonstrated that the products of two p53 target genes, in. Evidence from human embryonic kidney–293 T(HEK-293T) cells indicate that sestrin2 is a BCAAs sensor regulator of physiological aging. The mTOR signaling pathway is the most important one that BCAAs participate in. This pathway plays a crucial role in the regulation of cellular growth, survival, and metabolism. BCAAs are also signaling molecules that are involved in the mTOR signaling pathway. It was reported that BCAAs catabolism is a conserved metabolic and mitochondrial compromise. These observations may help us understand the above findings.

During adult aging, within-individual fasting serum BCAA levels may be fairly stable. Accordingly, the lower BCAA levels of the oldest old may be due to selective survival. In other words, higher mortality rates for middle-aged people with high BCAA levels may leave only the people who have always had relatively low BCAA levels to survive to 85+ and therefore be available for inclusion in this oldest old group. In our study, the positive

Table 3. Combined associations of serum BCAAs and frailty score in the oldest-old subjects. BCAA, branched-chain amino acids; Val, valine; Leu, leucine; Ile, isoleucine; LTL, leukocyte telomere length; 95% CI: 95% confidence interval; BMI, body mass index. *β refers to the average change of frailty score by one standard deviation increase in amino acids concentration. Model 1: crude. Model 2: adjusted for age and BMI.

The reasons and mechanisms underlying this finding need to be further explored. In addition to being proteogenic amino acids, BCAAs are also signaling molecules. It was reported that BCAAs catabolism is a conserved regulator of physiological aging. The mTOR signaling pathway is the most important one that BCAAs participate in. Evidence from human embryonic kidney–293 T(HEK-293T) cells indicate that sestrin2 is a BCAAs sensor for the mTORC1 pathway. And previous studies have demonstrated that the products of two p53 target genes, Sestrin1 and Sestrin2, connect genotoxic Stress and mTOR Signaling. Moreover, the evidence also indicated that telomere shortening activates p53-mediated cellular growth arrest, senescence and apoptosis and induces metabolic and mitochondrial compromise. These observations may help us understand the above findings.

During adult aging, within-individual fasting serum BCAA levels may be fairly stable. Accordingly, the lower BCAA levels of the oldest old may be due to selective survival. In other words, higher mortality rates for middle-aged people with high BCAA levels may leave only the people who have always had relatively low BCAA levels to survive to 85+ and therefore be available for inclusion in this oldest old group. In our study, the positive
association between BCAAs and LTL was not found in the oldest-old, which may due to a potential physiological shift from midlife (an anabolic state) to late life (a catabolic state) (Fig. 3). So, it is unreasonable that most of the medical guidelines for elderly subjects are still derived from studies of middle-aged. Likewise, there was no significant association between LTL and frailty score, which is consisted with other studies19, supporting the hypothesis that telomere length may be not a meaningful biomarker for frailty.

Although there are some limitations, such as a cross-sectional design and a limited sample size, this is the first study to explore the association between serum BCAAs, LTL and frailty based on the subjects from a longevity county in East Asia.

In the future, we will further control the confounding of malnutrition in the oldest old and exclude those subjects and test the reproducibility of our findings by a longitudinal study design with a larger sample size and multiple aging-related endpoints, including all-cause mortality.

Conclusion
In summary, our findings suggest a potentially protective effect of circulating BCAAs on LTL and frailty based on the subjects from longevity county in East Asia and further indicate a potential synergetic interaction between BCAAs and LTL in healthy aging.

Methods
Study design and participants. A cross-sectional study was conducted in this study. The subjects were recruited by a quota and judgment sampling method from Yongfu County, Guangxi Province, which was qualified as the longevity town by Geriatric Society of China in 200720. The oldest-old subjects were defined as successful agers aged above 8521. There are no lineal family members aged above 80 for 3 generations in middle-aged subjects.
Information collection. The information of demographic data, lifestyle and health status was obtained using a standardized questionnaire. It was conducted by trained and qualified personnel. The peripheral fasting blood samples were separated for laboratory testing. Serum samples were isolated and stored at −80 °C until analysis.

Determination of LTL. Genomic DNA was extracted by phenol-chloroform method. The DNA concentration and purity were assessed by measuring absorbance at 260 and 280 nm. The DNA integrity was tested by electrophoresis on a 1.0% agarose gel. The real-time qPCR method used for LTL measurement has been reported in detail previously25, which was widely used in large sample detection26,27. Briefly, LTL was measured in duplicate and expressed as a relative ratio of telomere repeat copy number to single copy gene (36B4) copy number compared to a reference standard (pooled genomic DNA generated within the lab). The primer sequences for the amplification reaction were 5′-GGTAAAAGTGGGTTAGGCTGAAGG-3′ (F-Tel), 5′-TCCGGACTATCCCTATCTATCCTATCCCTATCCCTA-3′ (R-Tel), 5′-CACCAAGTGGGAAGGTGTAATCC-3′ (F-36B4), and 5′-CCATTCTATCATCAACGGGTACAA-3′ (R-36B4).

Determination of serum BCAAs concentration. A targeted metabolomics approach based on isotope dilution liquid chromatography tandem mass spectrometry (LC/MS/MS) method was used for the measurement of BCAAs concentration. The protocol has been reported detailly in our previous work28,29. Numerically, BCAAs means the sum of the concentrations of serum Val, Leu and Ile.

Frailty score. To assess the health status in elderly people, a frailty score was defined as the proportion of accumulated deficits30,31 based on 24 general aging-related items (binary variables), including appearance features (11 items, e.g., dense wrinkles, yes or not), the ability of physical activity (3 items, e.g., walking on crutches, yes or not), the physical function (5 items, e.g., poor hearing, yes or not), the cognitive function (4 items, e.g., poor memory, yes or not) and disease (1 items, e.g., hypertension, yes or not) (Table S4). Each variable was coded as “0” (healthy) or “1” (unhealthy). The score can be calculated by summing the number of health deficits of each individual and dividing them by the total number of items measured30. The higher the score, the worse the physical condition. It is worth noting that this score assesses a more intuitive health status and reflects the characteristics of earlier aging compared with other studies.

Statistical methods. The continuous variables of normal distribution were described as means ± SD and compared by student t test or covariance analysis; the data of non-normal distribution was expressed by median (quartile spacing) and compared by nonparametric test; the categorical variables were presented as frequencies (percentages) and compared by Pearson Chi-square test. The associations between BCAAs, LTL and frailty score were estimated by partial correlation and multiple linear regression. Further interaction analysis between BCAAs (percentages) and compared by Pearson Chi-square test. The associations between BCAAs, LTL and frailty score.

Statistical methods. The continuous variables of normal distribution were described as means ± SD and compared by student t test or covariance analysis; the data of non-normal distribution was expressed by median (quartile spacing) and compared by nonparametric test; the categorical variables were presented as frequencies (percentages) and compared by Pearson Chi-square test. The associations between BCAAs, LTL and frailty score were estimated by partial correlation and multiple linear regression. Further interaction analysis between BCAAs and LTL was estimated from the general linear model by converting BCAAs and LTL into binary variables with a median split method. Smoothed lines between BCAAs, LTL and age were plotted with loess fitting using the R 3.4.3. Heatmaps were plotted by R 3.4.3. All statistical tests were two-sided, and P<0.05 was considered statistically significant. All analyses were performed using SPSS 22.0 (SPSS Inc.).

Ethical statement. The study was approved by the Ethics Committee of Beijing Hospital and was conducted according to the guidelines in the Declaration of Helsinki. All participants or their guardians provided written informed consent.

Data availability. The datasets generated during and/or analysed during the current study are available from the corresponding author on reasonable request.
