COMBINATORIAL DUALITY OF HILBERT SCHEMES OF POINTS IN THE AFFINE PLANE

MATHIAS LEDERER

Abstract. The Hilbert scheme of \( n \) points in the affine plane contains the open subscheme parametrizing \( n \) distinct points in the affine plane, and the closed subscheme parametrizing ideals of codimension \( n \) supported at the origin of the affine plane. Both schemes admit Białynicki-Birula decompositions into moduli spaces of ideals with prescribed lexicographic Gröbner deformations. We show that both decompositions are stratifications in the sense that the closure of each stratum is a union of certain other strata. We show that the corresponding two partial orderings on the set of of monomial ideals are dual to each other.

1. Introduction

The polynomial ring \( S := \mathbb{C}[x_1, x_2] \) in two variables is the coordinate ring of the affine plane \( \mathbb{A}^2 \) over the complex numbers. The Hilbert scheme of points in the affine plane \( H^n(\mathbb{A}^2) \) is the moduli space representing the functor which sends each \( \mathbb{C} \)-algebra \( A \) to the set of ideals \( I \subseteq S \otimes_{\mathbb{C}} A \) such that the quotient \( (S \otimes_{\mathbb{C}} A)/I \) is a locally free \( A \)-module of dimension \( n \). However, since we will only be working with \( \mathbb{C} \)-valued points, we think of \( H^n(\mathbb{A}^2) \) as the moduli space of ideals of codimension \( n \) in \( S \),

\[
H^n(\mathbb{A}^2) := \{ \text{ideals } I \subseteq S : \dim(S/I) = n \}.
\]

The scheme \( H^n(\mathbb{A}^2) \) is a smooth variety of dimension \( 2n \) [Fog68, Ha98].

The Hilbert scheme of points contains a subscheme

\[
H^n(\mathbb{A}^2) := \{ \text{ideals } I \subseteq S : \dim(S/I) = n, \supp(S/I) = \mathbb{V}(x_1, x_2) \}
\]
called the punctual Hilbert scheme. Upon identifying each ideal \( I \subseteq S \) defining a point in \( H^n(\mathbb{A}^2) \) with its affine subscheme \( \text{Spec}(S/I) \subseteq \mathbb{A}^2 \), we think of each point in \( H^n(\mathbb{A}^2) \) as a fat point of fatness \( n \) supported at the origin. Each ideal \( I \) defining a point in \( H^n(\mathbb{A}^2) \) can be factored into \( I = I_0 \cap \ldots \cap I_m \) such that \( \supp(S/I_j) \neq \supp(S/I_k) \) for \( j \neq k \), and each \( I_j \) defines a point in a translated version of \( H^n(\mathbb{A}^2) \), where \( n_j = \dim(S/I_j) \). The punctual Hilbert scheme may therefore be viewed as the fundamental building block from which the Hilbert scheme of points is assembled. This is the ultimate reason why the punctual Hilbert scheme is of crucial importance many aspects of the theory of Hilbert schemes, including

- Ellingsrud and Strømme determination of the Betti numbers of the Hilbert scheme of points in the projective plane [ES87, ES88];
- Grojnowski’s and Nakajima’s implementation of the ring of symmetric functions in terms of Hilbert schemes of points on surfaces;
- the ongoing project of describing the non-smooth, non-reduced and non-irreducible nature nature of the Hilbert schemes of points in \( d \)-space for \( d > 2 \), the contributors to which include Iarrobino, Emsalem [Iar72, IE78], Mazzola [Maz80], Cartwright, Erman, Velasco and Viray [CEVV09, Erm12].

The cited papers by Ellingsrud and Strømme are built around three actions of the one-dimensional torus \( \mathbb{C}^* \) on \( S \) inducing Białynicki-Birula decompositions of three types of Hilbert schemes. All actions are given by weights \( v = (v_1, v_2) \in \mathbb{Z} \). Upon using the multi-index notation \( x^\alpha := x_1^{\alpha_1} x_2^{\alpha_2} \), the actions are defined by

\[
G_m \subseteq S : t.x^\alpha = t^{(\alpha,v)}x^\alpha,
\]

where \( \langle a, v \rangle = a_1 v_1 + a_2 v_2 \). The first action is defined by a weight vector such that \( v_1 \ll v_2 < 0 \), more precisely, \( v_1 \leq nv_2 < 0 \). The fixed points of this action are monomial ideals \( M_\Delta \subseteq S \) of codimension \( n \). The indexing set here is the corresponding standard set, or staircases \( \Delta \subseteq \mathbb{N}^2 \) of cardinality \( n \), i.e., a set whose complement \( \mathbb{N}^2 \setminus \Delta \) is closed under addition of elements from \( \mathbb{N}^2 \). Exponentiation establishes the identification of complements of standard sets and monomial ideals. The Białynicki-Birula cells of the action (containing all ideals \( I \subseteq S \) floating into \( M_\Delta \) as \( t \to 0 \)) are lexicographic Gröbner strata or lexicographic Gröbner basins

\[
H^\Delta_{\text{lex}}(\mathbb{A}^2) := \{ \text{ideals } I \subseteq S : \text{in}_{\text{lex}}(I) = M_\Delta \}.
\]

Here \( \text{in}_{\text{lex}}(I) \) denotes the lexicographic initial ideal, or lexicographic Gröbner deformation of \( I \), with respect to the lexicographic ordering in which \( x_1 > x_2 \). Thus the Białynicki-Birula decomposition reads

\[
H^n(\mathbb{A}^2) = \bigsqcup_{\Delta \in \text{st}_n} H^\Delta_{\text{lex}}(\mathbb{A}^2),
\]

where \( \text{st}_n \) denotes the set of staircases of cardinality \( n \). This last equation just rephrases the elementary fact that every ideals admits a unique lexicographic Gröbner basis.

The second type of action which Ellingsrud and Strømme will be discussed later in the paper. The third type is given by a weight vector such that \( 0 < v_1 \ll v_2 \), more precisely, \( 0 < nv_1 \leq v_2 \). The fixed points of this action are also the standard sets \( M_\Delta \) for \( \Delta \in \text{st}_n \). The limit \( \lim_{t \to 0} t \cdot I \) exists in \( S \) only if \( I \) is supported at the origin. This follows from the naïve observation that if \( t \cdot I \) tends to \( M_\Delta \), then the support of \( t \cdot I \) tends to the support of \( M_\Delta \), together with the simple fact that our torus action on \( \mathbb{A}^2 \) is given by \( t \cdot (a_1, a_2) = (t^{-v_1} a_1, t^{-v_2} a_2) \) on coordinates, which will fly off to infinity unless \( (a_1, a_2) = (0, 0) \). As for a schematic treatment of this observation, see [EL12]. It therefore only makes sense to consider this action on \( H^n,\text{punc}(\mathbb{A}^2) \). The Białynicki-Birula decomposition then reads

\[
H^n,\text{punc}(\mathbb{A}^2) = \bigsqcup_{\Delta \in \text{st}_n} H^\Delta_{\text{lex}}(\mathbb{A}^2),
\]

where

\[
H^\Delta_{\text{lex}}(\mathbb{A}^2) := H^\Delta_{\text{lex}}(\mathbb{A}^2) \cap H^n_{\text{lex}}(\mathbb{A}^2).
\]

Remember that \( H^n,\text{punc}(\mathbb{A}^2) \) parametrizes points of fatness \( n \) supported at the origin. Equation (2) thus distinguishes those points according to the shapes of their respective fatnesses.

Decomposition (2) arises from decomposition (1) by intersecting both sides with the closed subscheme \( H^n,\text{punc}(\mathbb{A}^2) \) of \( H^n(\mathbb{A}^2) \). Consider the open subscheme

\[
H^n,\text{ét}(\mathbb{A}^2) := \{ \text{ideals } I \subseteq S : \dim(S/I) = n, |\text{supp}(S/I)| = n \}
\]

of \( H^n(\mathbb{A}^2) \). The superscript stands for \( \text{étale} \), since \( H^n,\text{ét}(\mathbb{A}^2) \) is in fact represents the functor which sends each \( \mathbb{C} \)-algebra \( A \) to the set of ideals \( I \subseteq S \otimes_{\mathbb{C}} A \) such that the projection \( \text{Spec}(S \otimes_{\mathbb{C}} A)/I \to \text{Spec} A \) is an \( \text{étale} \) morphism of degree \( n \) [Led13]. The two schemes \( H^n,\text{punc}(\mathbb{A}^2) \) and \( H^n,\text{ét}(\mathbb{A}^2) \) may be viewed as antagonists of each other, since the first parametrizes ideals whose corresponding scheme is a fat point supported at the origin, whereas the second parametrizes ideals whose corresponding scheme contains no fat points at all. Another way of viewing \( H^n,\text{punc}(\mathbb{A}^2) \) and \( H^n,\text{ét}(\mathbb{A}^2) \) as antipodes of each other is the fact that \( H^n,\text{punc}(\mathbb{A}^2) \) is the preimage of \( n \) copies of the origin under the Hilbert-Chow morphism

\[
a_n : H^n,\text{ét}(\mathbb{A}^2) \to (\mathbb{A}^2)^{(n)} := (\mathbb{A}^2)^n/S_n,
\]

whereas \( H^n,\text{ét}(\mathbb{A}^2) \) is the open locus where the Hilbert-Chow morphism is an isomorphism [Ber12] Section 2]. Upon intersecting both sides of (1) with the open subscheme \( H^n,\text{ét}(\mathbb{A}^2) \) of \( H^n(\mathbb{A}^2) \), we obtain

\[
H^n,\text{ét}(\mathbb{A}^2) = \bigsqcup_{\Delta \in \text{st}_n} H^\Delta_{\text{lex}}(\mathbb{A}^2).
\]

The goal of the present paper is to show that decompositions (2) and (3) are antagonists of each other in a combinatorial sense. The crucial notion for this are two partial orderings on \( \text{st}_n \).
Definition 1.  
- Take an arbitrary $\Delta \in \text{st}_n$, and let $R := \{\Delta_0, \ldots, \Delta_l\}$ be the multiset of rows of $\Delta$. So each $\Delta_i$ is a one-dimensional standard set, i.e., a finite interval in $\mathbb{N}$ starting at 0. Let $R = R_0 \sqcup \ldots \sqcup R_m$ be any partition. For each $j$, we let $\Delta_j'$ be the one-dimensional standard set whose cardinality is the sum of the cardinalities of elements of $R_j$. Then the multiset $R' := \{\Delta_0', \ldots, \Delta_m'\}$ is the multiset of rows of a standard set $\Delta' \in \text{st}_n$.
- We define $\Delta \leq_{\text{ét}} \Delta'$ if, and only if, $\Delta'$ arises from $\Delta$ by the above-described process.
- We define $\Delta \leq_{\text{punc}} \Delta'$ if, and only if, $(\Delta')^t \leq_{\text{ét}} \Delta'$, the superscript $t$ standing for transposition of standard sets.

Figures 1 and 2 show the Hasse diagrams of $\leq_{\text{ét}}$ and $\leq_{\text{punc}}$, respectively, on standard sets of size 6. Arrows point from smaller to larger elements.

**Theorem 2.**  
(i) The closure of $H^{\Delta,\text{ét}}_{\text{lex}}(\mathbb{A}^2)$ in $H^n,\text{ét}(\mathbb{A}^2)$ is the union of all $H^{\Delta',\text{ét}}_{\text{lex}}(\mathbb{A}^2)$ such that $\Delta' \leq_{\text{ét}} \Delta$.
(ii) The closure of $H^{\Delta,\text{punc}}_{\text{lex}}(\mathbb{A}^2)$ in $H^n,\text{punc}(\mathbb{A}^2)$ is the union of all $H^{\Delta',\text{punc}}_{\text{lex}}(\mathbb{A}^2)$ such that $\Delta' \leq_{\text{punc}} \Delta$.
(iii) In particular, decompositions (2) and (3) are stratifications whose partial orderings on $\text{st}_n$ are $\leq_{\text{ét}}$ and $\leq_{\text{punc}}$, respectively.

Here we use the term **stratification** in the strict sense, namely, for a decomposition

$$X = \coprod_{i \in S} X_i$$

of a topological space $X$ into locally closed subspaces $X_j$ such that the closure of each $X_j$ is a union of certain $X_i$. This datum induces a partial ordering $\preceq$ on the indexing set $S$ in which $i \preceq j$ if, and only if, $\overline{X_i} \supseteq X_j$.

As for the organization of the paper, in Section 2 we provide some basics about a combinatorial operation on standard sets called **Connect Four** which secretly defines the partial orderings $\leq_{\text{et}}$ and $\leq_{\text{punc}}$, and which controls the combinatorics of lexicographic Gröbner basins in $H^n(A^2)$. (The same operation also controls the geometry of lexicographic Gröbner basins in $H^n,\text{et}(A^d)$ when $d \geq 3$ [Led13]. However, that geometry is trivial in the plane case. The author’s long-term project is to generalize the findings from the present paper from the plane case to $d \geq 3$.) With the prerequisites from that section at hand, the proof of Theorem 2 (i) is not hard; we shall do this in Section 3. The proof of Theorem 2 (ii), which takes considerably more effort, shall be carried out in Section 4. We conclude the paper with a few results and one conjecture on incidences among Gröbner basins in $H^n(A^2)$ in Section 5.

Acknowledgements

I wish to thank Allen Knutson and Jenna Rajchgot for our longstanding research collaboration on Hilbert schemes—and many other things. Many thanks go to Anthony Iarrobino for inviting me to Boston, for giving me the opportunity to present my work at the GASC seminar and the AMS Special Session on Hilbert schemes, and for many fruitful and supportive comments about my work. I am particularly indebted to Laurent Evain. Laurent and I stated and proved Propositions 3 and 4 in joint effort. Special thanks go to my students Daniel Heinrich and Patrick Wegener. I wrote large parts of this paper while teaching a course on Hilbert schemes, in which I got much inspiration from the two. A preliminary account of the work presented here was presented at Max Planck Institut für Mathematik at Bonn. I wish to thank Bernd Sturmfels for inviting me there.

2. C4 in two different directions

For two-dimensional standard sets $\Delta$ and $\Delta'$, we define their **C4 sum in the first direction** as

$$\Delta +_1 \Delta' := \left\{ \alpha \in \mathbb{N}^2 : p_1(\alpha) < \left| p_2^{-1}(p_2(\alpha)) \cap \Delta \right| + \left| p_2^{-1}(p_2(\alpha)) \cap \Delta' \right| \right\}$$

and their **C4 sum in the second direction** as

$$\Delta +_2 \Delta' := \left\{ \alpha \in \mathbb{N}^2 : p_2(\alpha) < \left| p_1^{-1}(p_1(\alpha)) \cap \Delta \right| + \left| p_1^{-1}(p_1(\alpha)) \cap \Delta' \right| \right\}.$$ 

So $\Delta +_1 \Delta'$ arises by arranging the columns of $\Delta$ and of $\Delta'$ in decreasing order from left to right, and $\Delta +_2 \Delta'$ arises by arranging the rows of $\Delta$ and of $\Delta'$ in decreasing order from bottom to top. Figure 3 shows C4 sums in either direction; the picture explains the terminology, which is reminiscent of the popular two-player game **Connect Four**.

The following statement appears without proof in Section 7.2 of [Nak99].

**Proposition 3.** For $i = 0, \ldots, m$, let $I_j \subseteq S$ be ideals in $H^\Delta_{\text{lex}}(A^2)$ with distinct supports on the axis $V(x_2)$. Let

$$I := \bigcap_{j=0}^m I_j.$$ 

Then $\text{in}_{\text{lex}}(I) = M_\Delta$, where

$$\Delta := \sum_{j=0}^m \Delta_j.$$ 

**Proof.** It suffices to prove the proposition in the case where each $I_j$ is supported in one point on the $x_1$-axis. We call the elements of the minimal generating system of the $\mathbb{N}^2$-module $\mathbb{N}^2 \setminus \Delta$ the **outer corners** of $\Delta$.

We have to prove, for each outer corner $\alpha$ of $\Delta$, the existence of an $f \in I$ with initial term $x^\alpha$. Upon defining $\alpha_{1,j} := \left| p_2^{-1}(p_2(\alpha)) \cap \Delta_j \right|$, 

$$\alpha_{1,j} := \left| p_2^{-1}(p_2(\alpha)) \cap \Delta_j \right|.$$
we see that \((a_{1,j}, a_2) \in \mathbb{N}^2 \setminus \Delta_j\), which implies the existence of a polynomial \(f_j \in I_j\) with initial exponent \((a_{1,j}, a_2)\). Lemma 4 implies that among those \(f_j\), there is one divisible by \(x_2^{a_2}\), so \(f_j = x_2^{a_2}p_j\) for some \(p_j \in S\) with initial exponent \(a_{1,j}\): If \((a_{1,j}, a_2)\) is an outer corner of \(\Delta_j\), then take the corresponding element of the lexicographic Gröbner basis. Otherwise, some \((a_{1,j}, a_2 - b)\) is an outer corner of \(\Delta_j\). In this case, take \(x_2^b\) times the corresponding element of the lexicographic Gröbner basis. The polynomial

\[
f := x_2^{a_2} \prod_{j=0}^{m} p_j,
\]

then has the initial term \(x^a\) since \(a_1 = a_{1,0} + \ldots + a_{1,m}\) by definition of \(a_{1,j}\).

**Lemma 4.** Let \(I \in H_{\text{lex}}(\mathbb{A}^2)\) be supported on \(\mathbb{V}(x_2)\) and \(\alpha\) be an outer corner of \(\Delta\). If \(f_\alpha\) is the element of the reduced lexicographic Gröbner basis of \(I\) with initial exponent \(\alpha\) and trailing exponents in \(\Delta\), then \(f_\alpha\) is divisible by \(x_2^{a_2}\).

**Proof.** The elements of the reduced lexicographic Gröbner basis of \(I\) take the shape

\[
f_\alpha = x^a + \sum_{\beta \in \Delta, \beta < \alpha} c_\beta x^\beta,
\]

where \(a\) runs through the set of outer corners of \(\Delta\). Consider the C*-action with a weight \(v' \in \mathbb{Z}^2\) such that \(v'_1 < 0\) and \(v'_2 = 0\). The ideal \(I' := \lim_{t \to 0} t.I\) defines a point in \(H_{\text{lex}}(\mathbb{A}^2)\). The elements \(f'_\alpha\) of its reduced lexicographic Gröbner basis of \(I'\) arise from the elements of the reduced lexicographic Gröbner basis of \(I\) by killing all coefficients \(c_\beta\) such that \(\beta_1 < a_1\). Each polynomial \(f'_\alpha\) therefore factors as \(f'_\alpha = x_2^{a_2}g'_\alpha\) for some \(g'_\alpha \in \mathbb{C}[x_2]\). If \(g'_\alpha\) was not divisible by \(x_2^{a_2}\), then it would contain a factor \(x_2 - \zeta\) for some \(\zeta \neq 0\). Since the ideal \(I'\) is supported at the origin, a factor \(x_2 - \zeta\) is not allowed to show up in the reduced lexicographic Gröbner basis. Therefore, \(c_\beta = 0\) for \(a_1 = \beta_1\) and \(\beta_2 < a_2\).

Let \(P\) be the set of pairs \((\alpha, \beta)\) consisting of an outer corner \(\alpha\) and an element \(\beta\) of \(\Delta\) such that \(c_\beta \neq 0\) and \(\beta_2 < a_2\). We order the elements of \(P\) in the decreasing way according to the slope of the line through \(\alpha\) and \(\beta\). Let \((\alpha'', \beta'')\) be the first element of \(P\) and \(s''\) the corresponding slope. Consider the C*-action with a weight \(v'' \in \mathbb{Z}^2\) perpendicular to \(s''\) such that \(v''_1 < 0\). The ideal \(I'' := \lim_{t \to 0} t.I\) defines a point in \(H_{\text{lex}}(\mathbb{A}^2)\). The element \(f''_\alpha\) of its reduced lexicographic Gröbner basis arises from \(f_\alpha\) by killing all \(c_\beta\) such that \(\beta\) is not on the line through \(\alpha\) of slope \(s''\). If one of the remaining \(c_\beta\) didn’t vanish, then arguments analogous to those we used for \(I'\) would lead to a contradiction to \(\text{supp}(I'') = \mathbb{V}(x_1, x_2)\). Therefore, \(c_\beta = 0\) for all \(\beta\) sitting on the line through \(\alpha\) of slope \(s''\). Then we take the next element \((\alpha''', \beta''')\).
of \( P \), and show that \( \epsilon_\beta = 0 \) for all \( \beta \) sitting on the line through \( \alpha \) of slope \( s^m \). Proceeding until the last element of \( P \) proves the lemma.

The next statement is a refined version of the main theorem of [Led08].

**Proposition 5.** For \( i = 0, \ldots, m \), let \( I_j \subseteq S \) be ideals in \( H^*_{\text{lex}}(\mathbb{A}^2) \) supported on distinct horizontal lines \( \mathbb{V}(x_2 - \lambda_j) \). Let

\[
I := \bigcap_{j=0}^{m} I_j.
\]

Then \( \text{in}_{\text{lex}}(I) = M_\Delta \), where

\[
\Delta := \sum_{i=0}^{m} \Delta_i.
\]

**Proof.** Consider the Lagrange interpolation polynomial

\[
\chi_j := \prod_{j' \in \{0, \ldots, m\} \setminus \{j\}} \frac{x_2 - \lambda_{j'}}{\lambda_j - \lambda_{j'}} \in \mathbb{C}[x_2].
\]

The sum of all \( \chi_j \) is the constant polynomial 1, thus also \( (\chi_0 + \ldots + \chi_m)^N = 1 \) for all \( N \). We expand this power using the multinomial theorem,

\[
\sum_{N_0 + \ldots + N_m = N} \binom{N}{N_0, \ldots, N_m} x_0^{N_0} \ldots x_m^{N_m} = 1.
\]

Let \( h_{j'} := h(\Delta_{j'}) \), then Lemma 4 implies that the power \( (x_2 - \lambda_{j'})^{h_{j'}} \) lies in \( I_{j'} \). We define \( H := \max\{h_0, \ldots, h_m\} \). For all \( j \), let

\[
L_j := \{ (N_0, \ldots, N_m) : N_0 + \ldots + N_m = N, N_j \geq H \}.
\]

Then for all \( (N_0, \ldots, N_m) \in L_j \), the product \( x_0^{N_0} \ldots x_m^{N_m} \) lies in \( \cap_{j' \in \{0, \ldots, m\} \setminus \{j\}} I_{j'} \). Moreover, as long as we choose \( N \) large enough, the union of all \( L_j \) is the full indexing set of the sum in 5. However, \( L_j \) and \( L_{j'} \) may overlap for \( j \neq j' \). We therefore pass to a patching of the indexing set by \( L_j' \subseteq L_j \) which don’t overlap. Then

\[
e_j := \sum_{(N_0, \ldots, N_m) \in L_j'} \binom{N}{N_0, \ldots, N_m} x_0^{N_0} \ldots x_m^{N_m} \in \bigcap_{j' \in \{0, \ldots, m\} \setminus \{j\}} I_{j'},
\]

and \( \epsilon_0 + \ldots + \epsilon_m = 1 \).

For proving that \( \Delta \) is the standard set of \( I \), we show, for each outer corner \( \alpha \) of \( \Delta \), the existence of an \( f_\alpha \in I \) with initial exponent \( \alpha \). Upon defining

\[
\alpha_{2,j} := \left| p_1^{-1}(p_1(\alpha)) \right| \cap \Delta_j,
\]

we see that \( (\alpha_1, \alpha_{2,j}) \in \mathbb{N}^2 \setminus \Delta_j \), which implies the existence of a polynomial \( f_j \in I_j \) with initial exponent \( (\alpha_1, \alpha_{2,j}) \). We write this polynomial as

\[
f_j = x_1^{\alpha_1} p_j + r_j,
\]

where \( p_j \in \mathbb{C}[x_2] \) is monic with initial exponent \( \alpha_{2,j} \) and all terms of \( r_j \in S \) are lexicographically smaller than \( x_1^{\alpha_1} \). In other words, the powers of \( x_1 \) appearing in \( r_j \) do not exceed \( x_1^{\alpha_1 - 1} \). We define

\[
f := \sum_{j \in \{0, \ldots, m\}} f_j \epsilon_j \prod_{j' \in \{0, \ldots, m\} \setminus \{j\}} p_{j'}.
\]

Then \( f \in I \) since \( f_j \in I_j \) and \( \epsilon_j \in \cap_{j' \in \{0, \ldots, m\} \setminus \{j\}} I_{j'} \). Moreover, \( f \) expands into

\[
f = \sum_{j \in \{0, \ldots, m\}} x_1^{\alpha_1} \epsilon_j \prod_{j' \in \{0, \ldots, m\}} p_{j'} + \sum_{j \in \{0, \ldots, m\}} r_j \epsilon_j \prod_{j' \in \{0, \ldots, m\} \setminus \{j\}} p_{j'}.
\]
The first sum reduces to $x_1^{a_1} \prod_{j \in \{1, \ldots, m\}} p_j^{k_j}$, whose initial exponent is $a$, since $a_2 = a_{2,0} + \ldots + a_{2,m}$ by definition of $a_{2,j}$. All terms of the second sum are lexicographically smaller than $x_1^{a_1}$. The polynomial $f$ therefore has the desired properties.

\section{Incidences on the étale part}

Before proving Theorem\ref{2}(i), two preliminary remarks are in order. The first remark is of a geometric nature. Remember from the Introduction that $H^{n,\text{ét}}(\mathbb{A}^2)$ is the open locus of $H^n(\mathbb{A}^2)$ on which the Hilbert-Chow morphism $\alpha_n$ is an isomorphism. The image of $H^{n,\text{ét}}(\mathbb{A}^2)$ under $\alpha_n$ is the symmetric product $$(\mathbb{A}^2)^{(n)} := ((\mathbb{A}^2)^n \setminus \Lambda) / S_n$$ where $\Lambda$ is the large diagonal, i.e., the locus where at least two points in $(\mathbb{A}^2)^n$ coincide, and $S_n$ is the symmetric group acting by permutation of the factors \cite[Section 2]{Ber12}. The identification of points in $H^{n,\text{ét}}(\mathbb{A}^2)$ and $(\mathbb{A}^2)^{(n)}$ sends an ideal $I$ to the set $\text{supp}(S/I)$, whose cardinality is $n$. We therefore always think of points in $H^{n,\text{ét}}(\mathbb{A}^2)$ as collections of $n$ reduced points in $\mathbb{A}^2$.

The second remark is of a combinatorial nature. We reformulate the partial ordering $\leq_{\text{ét}}$ in terms of $C_4$ sums. A standard set $\Delta$ is the $C_4$ sum in the second direction of its rows,

$$\Delta = \sum_{\Delta \in \text{rows}^{(2)}(\Delta)} \Delta_i,$$

where $\text{rows}(\Delta)$ denotes the multiset of rows of $\Delta$. Definition\ref{1} then says that $\Delta \leq_{\text{ét}} \Delta'$ if, and only if, there exists a partition $\text{rows}(\Delta) = R_0 \bigsqcup \ldots \bigsqcup R_l$ such that

$$\Delta' = \sum_{j=0}^l \left( \sum_{i \in R_j} \Delta_i \right).$$

The rows of $\Delta'$ appear in the parentheses in the last displayed equation; they are just the horizontal concatenation of certain rows of $\Delta$. We therefore also express the inequality $\Delta \leq_{\text{ét}} \Delta'$ by saying that $\Delta'$ arises from $\Delta$ by merging rows.

\textbf{Proof of Theorem\ref{2}(i).} Let $\Delta \in \text{st}_n$ and $\text{rows}(\Delta) := \{\Delta_0, \ldots, \Delta_l\}$ be the multiset of its rows. Let $I \subseteq S$ be an ideal defining a point in $H^{n,\text{ét}}(\mathbb{A}^2)$. We write $A := \text{supp}(S/I) \subseteq \mathbb{A}^2$ for the set of $n$ points corresponding to $I$. Propositions\ref{3} and\ref{5} imply that $I$ defines a point in $H_{\text{lex}}^n(\mathbb{A}^2)$ if, and only if,

- $|\Delta_0|$ points of $A$ sit on a horizontal line $\mathbb{V}(x_2 - \lambda_0)$,
- $|\Delta_1|$ points of $A$ sit on a horizontal line $\mathbb{V}(x_2 - \lambda_1)$,
- etc., and
- $|\Delta_i|$ points of $A$ sit on a horizontal line $\mathbb{V}(x_2 - \lambda_i)$,

and $\lambda_i \neq \lambda_j$ for $i \neq j$. Figure\ref{4} shows an example of a configuration of points defining an ideal $I \in H_{\text{lex}}^n(\mathbb{A}^2)$. The full moduli space $H_{\text{lex}}^n(\mathbb{A}^2)$ is then the space of configurations of $n$ points in which the horizontal lines may move freely along the $x_2$-axis as long as they don’t collide, and the points on each horizontal line $\mathbb{V}(x_2 - \lambda_i)$ may move freely along this line as long as they don’t collide.

Within the moduli space $H^n(\mathbb{A}^2)$, however, points have more freedom to move. Consider a configuration $A$ of $n$ reduced points defining a point in $H^\Lambda,\text{ét}(\mathbb{A}^2)$ such the one from Figure\ref{4}. Understanding to which configuration of $n$ reduced points the given configuration $A$ may degenerate without leaving $H^\Lambda,\text{ét}(\mathbb{A}^2)$ amounts to determining the closure of $H_{\text{lex}}^\Lambda(\mathbb{A}^2)$ in $H^{n,\text{ét}}(\mathbb{A}^2)$. Here is how to determine that degeneration: First off, none of the points sitting on a horizontal line $\mathbb{V}(x_2 - \lambda_i)$ may leave the line they sit on. Moreover, none of the points may collide with each other. However, it may and will happen that different horizontal lines merge into one. Of course if this happens, the points sitting on the respective lines will still stay away from each other. The combinatorial shadow of the merging process of horizontal
Figure 4. A configuration of points defining an ideal \( I \in H_{\text{lex}}^\Delta(A^2) \)

lines in \( A^2 \) is encoded in the partial ordering \( \leq_{\text{det}} \), as described earlier in the present section. What we have just proven is the inclusion

\[
\overline{H^\Delta(A^2)} \subseteq \bigcup_{\Delta' \leq \Delta} H_{\text{lex}}^{\Delta'}(A^2).
\]

As for the converse inclusion, it’s easy to see that each configuration \( A' \) of points corresponding to a point in \( H_{\text{lex}}^{\Delta'}(A^2) \) has arbitrarily close approximations by configurations \( A \) of points corresponding to points in \( H_{\text{lex}}^\Delta(A^2) \).

4. Incidences on the punctual part

We also start this section, in which we prove Theorem 2(ii), with two preliminary remarks. The first remark is of a geometric nature. Remember from the Introduction that Ellingsrud and Strømme defined three actions of \( C^* \) on \( S \) which induce Białynicki-Birula decompositions of three types of Hilbert schemes. We have already discussed the first and the third type of action. The second type uses a weight \( v \in \mathbb{Z}^2 \) such that \( v_1 < 0 < v_2 \). The fixed points of this action are once more the standard sets \( M_{\Delta} \) for \( \Delta \in \text{st}_n \). The limit \( \lim_{t \to 0} t.I \) of an ideal defining a point in \( H^n(A^2) \) exists in \( S \) only if \( I \) is supported on the axis \( \mathbb{V}(x_2) \).

It therefore only makes sense to consider this action on

\[
H^{\Delta,\text{lin}}(A^2) := \{ \text{ideals } I \subseteq S : \dim(S/I) = n, \text{ supp}(S/I) = \mathbb{V}(x_2) \}
\]

The Białynicki-Birula decomposition then reads

\[
H^{\Delta,\text{lin}}(A^2) = \bigcup_{\Delta \in \text{st}_n} H_{\text{lex}}^{\Delta,\text{lin}}(A^2),
\]

where

\[
H_{\text{lex}}^{\Delta,\text{lin}}(A^2) := H_{\text{lex}}^{\Delta}(A^2) \cap H_{\text{lex}}^{n,\text{lin}}(A^2).
\]

Note that we have implicitly been using schemes like \( H_{\text{lex}}^{\Delta,\text{lin}}(A^2) \) in Proposition 3 and Lemma 4 above.

with a later Ellingsrud and Stromme, with a later correction by Huibregtse, determined the dimensions of the Białynicki-Birula cells in \( H^n(A^2) \), \( H^{n,\text{lin}}(A^2) \) and \( H^{n,\text{punc}}(A^2) \), and related the three types of cells to each other. Conca and Valla proved the same result using a different approach.

Theorem 6. [ES87, ES88, Hui05, CV08] Let \( p_1, p_2 : \mathbb{N}^2 \to \mathbb{N} \) be the two projections, \( w(\Delta) := |p_1(\Delta)| \) the width and \( h(\Delta) := |p_2(\Delta)| \) the height of \( \Delta \in \text{st}_n \). Then

\[
H_{\text{lex}}^\Delta(A^2) \cong \mathbb{A}^{|\Delta|+h(\Delta)},
\]

\[
H_{\text{lex}}^{\Delta,\text{lin}}(A^2) \cong \mathbb{A}^{|\Delta|},
\]

\[
H_{\text{lex}}^{\Delta,\text{punc}}(A^2) \cong \mathbb{A}^{|\Delta|-w(\Delta)}.
\]
Moreover, the coefficients of the reduced lexicographic Gröbner basis of the universal family over $H^\Delta_{\text{lex}}(\mathbb{A}^2)$, which take the shape

$$f_{\alpha} = \sum_{\beta < \alpha} c_{\beta}^{\alpha} x^\beta,$$

for all outer corners $\alpha$ of $\Delta$, are polynomials in the coordinates of $\mathbb{A}^{h(\Delta)}$, and the two closed immersions

$$H^\Delta_{\text{lex}}(\mathbb{A}^2) \subseteq H^\Delta_{\text{lin}}_{\text{lex}}(\mathbb{A}^2) \subseteq H^\Delta_{\text{lex}}(\mathbb{A}^2)$$

are the immersions of coordinate subspaces in $\mathbb{A}^{h(\Delta)}$.

The second remark is a reformulation of the partial ordering $\leq_{\text{punc}}$ in terms of C4 sums, analogous to the reformulation of $\leq_{\text{et}}$ in the previous section. A standard set $\Delta$ is the C4 sum in the first direction of its columns,

$$\Delta = \sum_{\Delta_i \in \text{cols}(\Delta)} \Delta_i.$$

Then $\Delta \leq_{\text{punc}} \Delta'$ if, and only if, each column $\Delta_j$ vertically breaks into one or more pieces

$$\Delta_j = \sum_{i \in C(\Delta_j)} \Delta'_i, 
$$

for some indexing set $C(\Delta_j)$, such that $\Delta'$ is the C4 sum in the first direction of all pieces of all columns,

$$\Delta' = \sum_{\Delta_i \in \text{cols}(\Delta), \Delta'_i \in C(\Delta_j)} \Delta'_i.$$

We therefore also express the inequality $\Delta \leq_{\text{punc}} \Delta'$ by saying that $\Delta'$ arises from $\Delta$ by breaking certain rows apart.

Proof of Theorem 2(ii). Throughout the proof, the standard set $\Delta$ will be fixed. We will consider various $\Delta'$ such that $\Delta \leq_{\text{punc}} \Delta'$, always denoting the respective multiset of columns by $\text{cols}(\Delta) = \{\Delta_{0}, \ldots, \Delta_{w-1}\}$ and $\text{cols}(\Delta') = \{\Delta'_{0}, \ldots, \Delta'_{w'-1}\}$. We first take a specific $\Delta'$, namely, one for which only one column $\Delta'_{0}$ of $\Delta$ splits into no more than two columns $\Delta''_{0}$ and $\Delta''_{1}$ of $\Delta'$ and all other columns remain unchanged, so

$$\text{cols}(\Delta) \setminus \{\Delta_{0}\} = \text{cols}(\Delta') \setminus \{\Delta'_{0}, \Delta'_{1}\}.$$

In particular, the widths $w$ and $w'$ of $\Delta$ and $\Delta'$ differ by one, $w' = w + 1$. Let $\Delta' = \Delta'$ be a point in $H^\Delta_{\text{lex}}(\mathbb{A}^2)$. We will show that $\Delta'$ lies in the closure of $H^\Delta_{\text{lex}}(\mathbb{A}^2)$.

Theorem 6 implies that $H^\Delta_{\text{lex}}(\mathbb{A}^2)$ is an affine space of dimension $n$ and contains an open and dense subscheme the moduli space $X^\Delta'$ of ideals splitting into

$$I'' = \bigcap_{j = 0}^{w'-1} I''_j, 
$$

where each $I''_j$ lies in $H^\Delta_{\text{lex}}(\mathbb{A}^2)$ and is supported at $\mathcal{V}(x_1 + c_{j,0}, x_2)$ such that $c_{j,0} \neq c_{k,0}$ for $j \neq k$. Thus $I''_j$ is given by its reduced lexicographic Gröbner basis,

$$I''_j = \langle x_1 + \sum_{b \in \Delta'_j} c_{j,b} x_2^{|\Delta'_j|}, x_2^{|\Delta'_j|} \rangle, 
$$

so $\text{supp}(I''_j) = \mathcal{V}(x_1 + c_{j,0})$, such that $c_{j,0} \neq c_{k,0}$ for $j \neq k$. In other words, $\text{Spec} \left( \frac{S}{I''} \right)$ splits into $w'$ “tall” rather than “fat” points, the tallness of the factor $\text{Spec} \left( \frac{S}{I''_j} \right)$ being the column $\Delta'_j$ of $\Delta'$ (The same open and dense subscheme of $H^\Delta_{\text{lex}}(\mathbb{A}^2)$ is used in Section 7.2 of [Nak99].) The middle picture in Figure 5 shows $\mathcal{V}(I'')$ for an ideal $I''$ in the dense and open subscheme $X^\Delta'$ of $H^\Delta_{\text{lex}}(\mathbb{A}^2)$.
The ideal $I'$ defines a point in the closed subscheme $H^\Delta_{\text{lex}}(\mathbb{A}^2)$ of $H^\Delta_{\text{lex}}(\mathbb{A}^2)$. A point $I''$ in the open and dense subscheme $X^{\Delta'}$ of $H^\Delta_{\text{lex}}(\mathbb{A}^2)$ can therefore be chosen arbitrarily close to $I'$. The two factors $I''_j$ and $I'''_j$ of $I''$, whose corresponding schemes are tall points with standard sets $\Delta'_j$ and $\Delta'_j'$, respectively, are of particular interest to us. The reduced lexicographic Gröbner basis of $I''_j$ contains one polynomial $f_{(w,0)}$ with initial exponent $(w,0)$. The zeros of $f_{(w,0)}(x_1,0)$ are the $w$ distinct points in $\text{supp}(I'') \subseteq \mathcal{V}(x_2)$. Those coordinates of $\mathcal{V}(I'')$ from each other and from $I'$. Those coordinates of $\mathcal{V}(I'')$ which are separated from each other and from $I''_j$. This can be done such that the lexicographic Gröbner deformation of ideal $I''_j$ has the standard set $\Delta'_j + 1 \Delta'_j$. The ideal

$$I'' := I''_j \cap \left( \bigcap_{j \neq j_0} I''_j \right).$$

is a deformation of $I''$ which can be chosen arbitrarily close to $I''$. The schemes defined by ideals $I'$, $I''$ and $I'''$ are illustrated in Figure 5. What the picture doesn’t appropriately indicate is the location of the points in $\text{supp}(I'')$ and $\text{supp}(I''')$. These points should be thought of as sitting arbitrarily close to the origin.

Let $n_0 := |\Delta_j| + |\Delta'_j|$, and let $z_0 \in \mathcal{V}(x_2)$ be the support of $I''_j$. The $z_0$-translated version of the punctual Hilbert scheme is

$$H^\Delta_{\text{lex},z_0}(\mathbb{A}^2) := \{\text{ideals } I \subseteq S : \dim(S/I) = n_0, \text{ supp}(S/I) = z_0\}$$

and for each standard set $\Delta''$ of cardinality $n_0$, the $z_0$-translated version of the corresponding Białynicki-Birula cell is

$$H^\Delta_{\text{lex},z_0}(\mathbb{A}^2) := H^\Delta_{\text{lex}}(\mathbb{A}^2) \cap H^\Delta_{\text{lex},z_0}(\mathbb{A}^2).$$

The $z_0$-translated version of Lemma 3 below implies that the ideal $I'''_j$ lies in the closure of $H^\Delta_{\text{lex},z_0}(\mathbb{A}^2)$ in $H^\Delta_{\text{lex},z_0}(\mathbb{A}^2)$. So there exists an ideal $I''_j \in H^\Delta_{\text{lex},z_0}(\mathbb{A}^2)$ arbitrarily close to the ideal $I'''_j$. We use this ideal for defining

$$I^{(4)} := I''_j \cap \left( \bigcap_{j \neq j_0} I''_j \right).$$

Then $I^{(4)}$ lies in $H^\Delta_{\text{lex}}(\mathbb{A}^2)$ by Lemma 3.

We now have all tools for showing that $I'$ lies in the closure of $H^\Delta_{\text{lex}}(\mathbb{A}^2)$. Take an open neighborhood $U \subseteq H^\Delta_{\text{lex}}(\mathbb{A}^2)$ of $I'$. We can find an open $W \subseteq H^\Delta_{\text{lin}}(\mathbb{A}^2)$ such that $U = W \cap H^\Delta_{\text{punc}}(\mathbb{A}^2)$. By choosing $I''$ close enough to $I'$, $I'''$ close enough to $I''$, and $I^{(4)}$ close enough to $I'''$, we can have all these ideals lie in $W$. The ideal $I^{(4)}$ is not supported in the origin, but rather in $w$ points on the $x_1$-axis. Its reduced lexicographic Gröbner basis contains one polynomial $f_{(w,0)}$ with initial exponent $(w,0)$. The zeros of $f_{(w,0)}(x_1,0)$ are the $w$ points in $\text{supp}(S/I^{(4)})$. By suitably adjusting some of the coordinates...
of $H^{\Delta',\text{lin}}_{\text{lex}}(\mathbb{A}^2) \cong \mathbb{A}^n$ that show up in the polynomial terms for the coefficients of $f_{(w,0)}(x_1,0)$, we kill all trailing terms of $f_{(w,0)}(x_1,0)$. We perform the same adjustment to all elements of the lexicographic Gröbner basis of $I^{(4)}$ which, as we remember from Theorem 6, are polynomials in the coordinates of $H^{\Delta',\text{lin}}_{\text{lex}}(\mathbb{A}^2) \cong \mathbb{A}^n$. The ideal $I$ generated by these polynomials still lies in $H^{\Delta',\text{lin}}_{\text{lex}}(\mathbb{A}^2)$, and is supported in the origin by construction. If $I^{(4)}$ is close enough to $I'$, then the $w$ zeros of $f_{(w,0)}(x_1,0)$ are arbitrarily close to the origin. The above-defined readjustment of the coefficients of $f_{(w,0)}(x_1,0)$ therefore leaves the coordinates of $H^{\Delta',\text{lin}}_{\text{lex}}(\mathbb{A}^2) \cong \mathbb{A}^n$ arbitrarily close to their original values. The ideal $I$ then still lies in the open neighborhood $W$ of $I'$. It therefore lies in $U = W \cap H^{\Delta',\text{punc}}_{\text{lex}}(\mathbb{A}^2)$.

We have thus proved the inclusion

$$H^{\Delta',\text{punc}}_{\text{lex}}(\mathbb{A}^2) \subseteq H^{\Delta',\text{punc}}_{\text{lex}}(\mathbb{A}^2)$$

for the specific $\Delta'$ defined above. The same inclusion follows for all $\Delta'$ such that $\Delta <_{\text{punc}} \Delta'$ by induction over the poset $\mathfrak{t}_n$. This establishes the first half of the proof.

As for the second half, we first consider any standard set $\Delta'$ of cardinality $n$, and introduce a method for finding out whether or not $\Delta <_{\text{punc}} \Delta'$. We iteratively define multisets

- $C_0$ ("to be checked if splittable")
- $C_1$ ("splits")
- $C_2$ ("isn’t splittable")
- $C_0'$ ("to be checked if arises as a split product")
- $C_1'$ ("arises as a split product")
- $C_2'$ ("doesn’t arise as a split product")

by the algorithm from Figure 6.

```plaintext
C_0 \leftarrow \text{cols}(\Delta), C_1 \leftarrow \emptyset, C_2 \leftarrow \emptyset
C_0' \leftarrow \text{cols}(\Delta'), C_1' \leftarrow \emptyset, C_2' \leftarrow \emptyset
G \leftarrow \text{the identical function } C_0 \rightarrow \text{cols}(\Delta)

\textbf{while } C_2 = \emptyset \textbf{ do}
  \textbf{if } \text{some element of } C_0 \text{ is taller than the shortest element of } C_0' \text{ then}
    c \leftarrow \text{any element from } C_0 \text{ that is taller than the shortest element of } C_0'
    \text{split } c \text{ into } c = d + e, \text{ where } d \in C_0' \text{ and } e \text{ is possibly } \emptyset
    C_0 \leftarrow (C_0 \setminus \{c\}) \cup \{e\}
    C_0' \leftarrow \text{cols}(\Delta) \text{ sending all } f \neq c \text{ to } G(f) \text{ and } e \text{ to } G(c)
    C_1 \leftarrow \{ \sum_{1 \in G^{-1}(g)} f : g \in \text{cols}(\Delta) \}
    C_0' \leftarrow C_0' \setminus \{d\}
    C_1' \leftarrow C_1' \cup \{d\}
  \textbf{else}
    C_2 \leftarrow C_0
    C_2' \leftarrow \text{cols}(\Delta') \setminus C_1'
  \textbf{end if}
\textbf{end while}
\textbf{return } (C_1, C_2, C_1', C_2')
```

Figure 6. The iterative non-deterministic definition of $C_1$ and $C_1'$

This iteration will eventually terminate, but it isn’t deterministic. Its output depends on the choice of $c$ and $d$. It’s not hard to see that the space of all outputs of the algorithm includes the quadruple $(\text{cols}(\Delta), \emptyset, \text{cols}(\Delta'), \emptyset)$ if, and only if, $\Delta <_{\text{punc}} \Delta'$. From now on we deal with the complementary case, $\Delta \not<_{\text{punc}} \Delta'$, so $C_2, C_2' \neq \emptyset$ for every output $(C_1, C_2, C_1', C_2')$ of the algorithm. We define, for such every
such output,

$$\Delta_j := \sum_{c \in C_j} \epsilon_c,$$

$$\Delta'_j := \sum_{c \in C'_j} \epsilon_c$$

for $j = 1, 2$. The definitions imply that

- $|\Delta_1| = |\Delta'_1|$,  
- $n_2 := |\Delta_2| = |\Delta'_2| \neq 0$, and 
- every column of $\Delta_2$ is shorter than every column of $\Delta'_2$.

Let $I'$ be a point in $H^{A_{\text{punc}}}_{\text{lex}}(\mathbb{A}^2)$. For finishing the second half of the proof, we have to show that $I'$ is not contained in the closure of $H^{A_{\text{punc}}}_{\text{lex}}(\mathbb{A}^2)$. By wiggling certain parameters appearing in the generators of $I'$, similarly as we did in the first half of the proof, we deform $I'$ into an ideal $I'' \in H_{\text{lex}}^{A_{\text{lin}}}(\mathbb{A}^2)$ which splits into

$$I'' = I''_1 \cap I''_2,$$

$$I''_1 := \bigcap_{c \in C'_1} I''_c,$$

where

- each ideal $I''_c$ is supported in a point $z'_c$ on the $x_1$-axis,
- $I''_2$ is supported in $0$,
- all $z'_c$ are distinct, and distinct from $0$,
- each $I''_c$ has the standard set $\Delta'_c$, and
- $I''_1$ has the standard set $\Delta'_2$.

By construction of $\Delta'_1$, and by the same arguments that we employed in the first half of the proof, the ideal $I''_c$ is arbitrarily close to the closure of $H^{A_{\text{punc}}}_{\text{lex}}(\mathbb{A}^2)$. Moreover, each ideal $J \in H^{A_{\text{punc}}}_{\text{lex}}(\mathbb{A}^2)$ can analogously be deformed into

$$J' = J'_1 \cap J'_2,$$

$$J'_1 := \bigcap_{c \in C_1} J'_c,$$

such that $J'_1$ is arbitrarily close to $H^{A_{\text{punc}}}_{\text{lex}}(\mathbb{A}^2)$. It all therefore boils down to showing that $I''_2$ is not contained in the closure of $H^{A_{\text{punc}}}_{\text{lex}}(\mathbb{A}^2)$.

Consider the locus

$$U := H^{n_2_{\text{punc}}}_{\text{lex}}(\mathbb{A}^2) \setminus \{I \subseteq S : \text{rank} ((S/I) \cap \langle x_0^2, \ldots, x_2^{h(\Delta_2)} \rangle) \leq h(\Delta_2)\}.$$  

This is an open subscheme of $H^{n_2_{\text{punc}}}_{\text{lex}}(\mathbb{A}^2)$, since the locus we remove is defined by rank inequalities, i.e., the closed subscheme defined by a number of determinants. Then, on the one hand, $I''_2$ lies in $U$, since $S/I''_2$ has the basis $(x^a)_{a \in \Delta'_2}$ and the $h(\Delta_2) + 1$ monomials $x_2^0, \ldots, x_2^{h(\Delta_2)}$ are a subfamily of that basis.

On the other hand, Lemma 4 implies that the lexicographic Gröbner basis of an ideal $I_2 \in H^{A_{\text{punc}}}_{\text{lex}}(\mathbb{A}^2)$ contains the polynomial

$$f(0, h(\Delta_2)) := x_2^{h(\Delta_2)}.$$  

The family $(x_2^0, \ldots, x_2^{h(\Delta_2)})$ is therefore linearly dependent in $S/I_2$. This shows that $U \cap H^{A_{\text{punc}}}_{\text{lex}}(\mathbb{A}^2) = \emptyset$. We have thus found an open neighborhood of $I''_2$ which doesn’t meet $H^{A_{\text{punc}}}_{\text{lex}}(\mathbb{A}^2)$.

**Lemma 7.** Consider the two-dimensional standard set

$$\Delta := \{0\} \times [0, n-1],$$
and any two-dimensional standard set \( \Delta' \) of the same cardinality, \( n \). Then \( \Delta \leq_{\text{punc}} \Delta' \), and \( H_{\text{lex}}^{1, \text{punc}}(\mathbb{A}^2) \) is contained in the closure of \( H_{\text{lex}}^{1, \text{punc}}(\mathbb{A}^2) \) in \( H^n_{\text{punc}}(\mathbb{A}^2) \).

Proof. The first assertion is immediate from the definition of \( \leq_{\text{punc}} \). As for the second assertion, \( H^n_{\text{punc}}(\mathbb{A}^2) \) is irreducible of dimension \( n - 1 \) by [Bri77]. Moreover,

\[
H^{1}_{\text{lex}}(\mathbb{A}^2) \cap H^n_{\text{punc}}(\mathbb{A}^2) \cong \mathbb{A}^{n-1},
\]

the isomorphism sending a point with coordinates \( c_1, \ldots, c_{n-1} \) on the right-hand side to the ideal

\[
I := \langle x_1 + c_{n-1}x_1^{n-1} + \ldots + c_1x_2, x_2^n \rangle
\]

defining a point on the left-hand side. The closure of \( H_{\text{lex}}^{1, \text{punc}}(\mathbb{A}^2) \) is therefore the whole \( H_{\text{lex}}^{n, \text{punc}}(\mathbb{A}^2) \). \( \square \)

5. Weak incidences

A decomposition \( 4 \) of a topological space \( X \) into locally closed subspaces \( X_i \) raises the problem of relations among the subspaces \( X_i \). We speak of strong incidence if \( \overline{X_i} \supseteq X_j \) and of weak incidence if \( \overline{X_i} \cap X_j = \emptyset \). If \( 4 \) is a stratification, then strong and weak incidence are the same thing, and the incidence problem is encoded in the poset \( 5 \).

Given that the intersections of decomposition \( 1 \) of \( H^n(\mathbb{A}^2) \) with subschemes \( H^n_{\text{ét}}(\mathbb{A}^2) \) and \( H^n_{\text{punc}}(\mathbb{A}^2) \) are both stratifications, one wonders if that decomposition itself is a stratification. It isn’t.

**Non-Example 8.** Consider the standard sets \( \Delta \) and \( \Delta' \) from Figure 7. The scheme \( H_{\text{lex}}^{1, \text{punc}}(\mathbb{A}^2) \) is contained in the closure of \( H_{\text{lex}}^{1, \text{punc}}(\mathbb{A}^2) \) in \( H^6_{\text{punc}}(\mathbb{A}^2) \), and therefore, \( H_{\text{lex}}^{1, \text{punc}}(\mathbb{A}^2) \) intersects the closure of \( H_{\text{lex}}^{1, \text{punc}}(\mathbb{A}^2) \) in \( H^6(\mathbb{A}^2) \) nontrivially. However, \( H_{\text{lex}}^{1, \text{et}}(\mathbb{A}^2) \) doesn’t intersect the closure of \( H_{\text{lex}}^{1, \text{et}}(\mathbb{A}^2) \) in \( H^6_{\text{et}}(\mathbb{A}^2) \). The decomposition of \( H^6(\mathbb{A}^2) \) from \( 1 \) is therefore not a stratification.

\[
\Delta = \begin{array}{ccc}
\otimes & \otimes & \otimes \\
\otimes & \otimes & \otimes \\
\otimes & \otimes & \otimes \\
\end{array} \\
\Delta' = \begin{array}{ccc}
\otimes & \otimes & \otimes \\
\otimes & \otimes & \otimes \\
\otimes & \otimes & \otimes \\
\end{array}
\]

**Figure 7.** Two standard sets showing that \( H^n(\mathbb{A}^2) \) is not stratified by lexicographic Gröbner basins

Similar non-examples can be constructed for all \( n \geq 4 \). However, Theorem 2 and the results from Section 2 provide an ample supply of examples for weak incidence between Gröbner basins in \( H^n(\mathbb{A}^2) \).

**Example 9.** Consider two standard sets \( \Delta \) and \( \Delta' \) such that

\[
\Delta = \sum_{r \in \text{rows}(\Lambda)} \left( \sum_{b \in r} \Delta_b \right) \\
\Delta' = \sum_{r' \in \text{rows}(\Lambda')} \left( \sum_{b' \in r'} \Delta_{b'} \right)
\]

for a collection of standard sets \( \Delta_b \) indexed by the boxes \( b \) appearing a standard set \( \Lambda \), arranged row by row, and analogously,

\[
\Delta' = \sum_{r' \in \text{rows}(\Lambda')} \left( \sum_{b' \in r'} \Delta_{b'} \right)
\]

where \( \Delta \leq_{\text{et}} \Delta' \), \( f : \Lambda \to \Lambda' \) is a bijection sending elements from one and the same row of \( \Lambda \) to elements from one and the same row of \( \Lambda' \), and \( \Delta_b \leq_{\text{punc}} \Delta'_{f(b)} \) for all boxes \( b \) of \( \Lambda \). Then a proof similar to those from Sections 3 and 4 shows that

\[
H^1(\mathbb{A}^2) \cap H^{1, \text{punc}}(\mathbb{A}^2) \neq \emptyset.
\]

This is illustrated in Figure 8. An ideal \( I \in H^1(\mathbb{A}^2) \) splits into \( I = \cap_{b \in \Lambda} I_b \), where \( I_{\text{lex}}(I_b) = M_{\Delta_{b'}} \) indexed by the boxes \( b \) appearing in standard set \( \Lambda \) such that ideal indexed by boxes from one and the same
row of $\Lambda$ are supported on one and the same horizontal line in $\mathbb{A}^2$. Ideals having this property come in a subfamily of $H^n(\mathbb{A}^2)$. When passing to the limit in $H^n(\mathbb{A}^2)$ of such a family, at least three types of degenerations may happen:

- Horizontal lines may merge.
- Each ideal $I_b$ may degenerate into an ideal $I'_{b'}$ with a standard set $\Delta_{b'}$ such that $\Delta_b <_{\text{punc}} \Delta_{b'}$.
- Punctual ideals lying on the same horizontal line may merge horizontally.

All three types of degeneration show up in Figure 8. However, degeneration may also happen “diagonally”—in a way not captured by the three bulleted items above.

![Figure 8](image_url)

**Figure 8.** A point in $H^n,_{\text{punc}}(\mathbb{A}^2)$ and two approximations in $H^n,_{\text{lin}}(\mathbb{A}^2)$

We define a partial ordering $\leq$ on $\text{st}_n$ by setting

$$\Delta \leq \Delta' : \iff \forall j \in w(\Delta') : |\Delta \cap \{a \in \mathbb{N}^2 : p_1(a) \leq j\}| \geq |\Delta' \cap \{a \in \mathbb{N}^2 : p_1(a) \leq j\}|,$$

so for all $j$, the cardinality of the columns of $\Delta$ West of $j$ is larger than the cardinality of the corresponding columns of $\Delta'$. We claim that (6) is equivalent to the analogous statement for rows,

$$\Delta \leq \Delta' \iff \forall i \in h(\Delta) : |\Delta \cap \{a \in \mathbb{N}^2 : p_2(a) \leq i\}| \leq |\Delta' \cap \{a \in \mathbb{N}^2 : p_2(a) \leq i\}|.$$

Transposition of standard sets provides a symmetry of $\text{st}_n$ which reduces proof of the claim to showing that (6) implies (7). So let us assume that (6) holds and prove (7) by induction over $i$. For $j := w(\Delta')$, both sides of the inequality from (6) equal $n$. This implies that the lowest row of $\Delta$ cannot be longer than the lowest row of $\Delta'$, so the inequality from (7) holds true for $i := 0$. As for the induction step, let $i_0$ be the smallest hypothetical index for which (7) breaks, let $j_0$ be the length of the $(i_0 - 1)$-th row of $\Delta'$ from below (starting to count at 0), and let

$$m := |(\Delta \setminus \Delta') \cap \{a \in \mathbb{N}^2 : p_1(a) > j_0, p_2(a) < i_0\}|,$$

$$m' := |(\Delta' \setminus \Delta) \cap \{a \in \mathbb{N}^2 : p_1(a) > j_0, p_2(a) < i_0\}|,$$

$$d := m' - m.$$

Then our choice of $i_0$ implies that the length of the $i_0$-th row of $\Delta'$ from below is strictly smaller than the length of the corresponding row of $\Delta$ minus $d$. Our choice of $j_0$ implies that $\Delta$ and $\Delta'$ both contain the rectangle of height $i_0$ and width $j_0$ with left corner at the origin. Summing up the lengths of the first few columns, we obtain, on the one hand, that

$$|\Delta \cap \{a \in \mathbb{N}^2 : p_1(a) \leq j_0 - d - 1\}| \leq n - m - i_0(d + 1) - (d + 1),$$

since the number of boxes of $\Delta$ sitting strictly West of the $(j_0 - d)$-th column (starting to count at 0) is at least $m + i_0(d + 1) + (d + 1)$. On the other hand,

$$|\Delta' \cap \{a \in \mathbb{N}^2 : p_1(a) \leq j_0 - d - 1\}| = n - i_0(d + 1) - m'.$$

The last two displayed equations contradict the inequality from (6) for $j := j_0 - d - 1$. 

Proposition 10. Let $I' \subseteq S$ be an ideal defining a closed point in $H^\Delta_{\text{lex}}(\mathbb{A}^2)$ which also lies in the closure of $H^\Delta_{\text{lex}}(\mathbb{A}^2)$ in $H^n(\mathbb{A}^2)$. Then $\Delta \leq_{\text{rows}} \Delta'$ and $\Delta \leq_{\text{cols}} \Delta'$.

Proof. This is done in the same spirit as the last paragraph from the proof of Theorem 2 (ii). For the time being, we use the notation $N_j := \{a \in \mathbb{N}^2 : p_1(a) \leq j\}$ for all $j$. Consider the closed subschemes

$$Y_j := \{I \in H^n(\mathbb{A}^2) : \text{rank}(S/I \cap \langle x^a : a \in \mathbb{N}^2 \rangle) \leq |\Delta \cap N_j|\}$$

of $H^n(\mathbb{A}^2)$ and their intersection

$$Y := \bigcap_{j=0}^{w(\Delta)} Y_j.$$

For each $I \in H^\Delta_{\text{lex}}(\mathbb{A}^2)$ and each outer corner $\alpha$ of $\Delta$, there exists a unique polynomial $f_\alpha \in I$ with lex-initial exponent $\alpha$ and trailing exponents in $\Delta$. This implies that $I \in Y$, more precisely, that $H^\Delta_{\text{lex}}(\mathbb{A}^2)$ is a subscheme of $Y$. (Thorough schematic arguments for statements like this is given in [Led11], but shall not be carried out here.) Our given $I'$ arises as the limit of a flat family in $H^\Delta_{\text{lex}}(\mathbb{A}^2)$, so of a flat family in $Y$. The limit $I'$ therefore also lies in $Y$. For all $j$, the family $(x^a)_{\alpha \in \Delta'_j}$ is a basis of the subspace of $(S/I') \cap \langle x^a : a \in \mathbb{N}^2_j \rangle$. Thus

$$|\Delta'_j| = \text{rank}((S/I') \cap \langle x^a : a \in \mathbb{N}^2_j \rangle) \leq |\Delta_j|,$$

as was claimed. □

Evain [Eva02] has studied decompositions and weak incidences among locally closed schemes related to the punctual Hilbert scheme. However, the schemes he studied are not quite $H^{n,\text{punc}}(\mathbb{A}^2)$, but nevertheless, Proposition 10 below is somewhat related to Theorem 8 from his paper. The condition for weak incidence from Proposition 10 is only necessary and apparently not sufficient. For instance, the standard sets $\Delta$ and $\Delta'$ from Figure 9 have the property that $\Delta < \Delta'$, but Example 9 doesn’t reveal weak incidence.

$$\Delta = \begin{array}{cccc} & & & \\ & & & \\ & & & \\ & & & \\ \end{array} \hspace{1cm} \Delta' = \begin{array}{cccc} & & & \\ & & & \\ & & & \\ & & & \\ \end{array}$$

Figure 9. Two standard sets such that $\Delta < \Delta'$

$$\begin{array}{cccc} & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ \end{array} \rightarrow \begin{array}{cccc} & & & \\ & & & \\ & & & \\ & & & \\ \end{array} \rightarrow \begin{array}{cccc} & & & \\ & & & \\ & & & \\ & & & \\ \end{array} \rightarrow \begin{array}{cccc} & & & \\ & & & \\ & & & \\ & & & \\ \end{array} \rightarrow \begin{array}{cccc} & & & \\ & & & \\ & & & \\ & & & \\ \end{array} \rightarrow \begin{array}{cccc} & & & \\ & & & \\ & & & \\ & & & \\ \end{array}$$

Figure 10. The common refinement of partial orderings $\leq_{\text{ét}}$ and $\leq_{\text{punc}}$ on $\text{st}_6$
Figure 11. Two standard sets such that both choices $\Delta \prec \Delta'$ and $\Delta' \prec \Delta$ refine $\leq_{\text{et}}$ and $\leq_{\text{punc}}$.

We conclude this paper with a combinatorial conjecture.

**Conjecture 11.** There exists a total ordering on $\text{st}_n$ refining both $\leq_{\text{et}}$ and $\leq_{\text{punc}}$.

Figure 10 shows the unique total ordering on $\text{st}_6$ refining both $\leq_{\text{et}}$ and $\leq_{\text{punc}}$. Readers are invited to check that the set $\text{st}_7$ admits two total orderings refining both $\leq_{\text{et}}$ and $\leq_{\text{punc}}$. The order of the standard sets from Figure 11 can be chosen freely.
