LOWEST-ORDER EQUIVALENT NONSTANDARD FINITE ELEMENT METHODS FOR BIHARMONIC PLATES

CARSTEN CARSTENSEN\textsuperscript{1,2} AND NEELA NATARAJ\textsuperscript{2,*}

Abstract. The popular (piecewise) quadratic schemes for the biharmonic equation based on triangles are the nonconforming Morley finite element, the discontinuous Galerkin, the $C^0$ interior penalty, and the WOPSIP schemes. Those methods are modified in their right-hand side $F \in H^{-2}(\Omega)$ replaced by $F \circ (J_{IM})$ and then are quasi-optimal in their respective discrete norms. The smoother $J_{IM}$ is defined for a piecewise smooth input function by a (generalized) Morley interpolation $I_{IM}$ followed by a companion operator $J$. An abstract framework for the error analysis in the energy, weaker and piecewise Sobolev norms for the schemes is outlined and applied to the biharmonic equation. Three errors are also equivalent in some particular discrete norm from [Carstensen, Gallistl, Nataraj, ESAIM: M2AN 49 (2015) 977–990.] without data oscillations. This paper extends the work [Veeseer and Zanotti, SIAM J. Numer. Anal. 56 (2018) 1621–1642] to the discontinuous Galerkin scheme and adds error estimates in weaker and piecewise Sobolev norms.

1. Introduction

The paper contributes to lower-order nonstandard finite element methods for a biharmonic plate problem in a real Hilbert space $(V, a)$. Given $F \in L^2(\Omega)$, [23] compares the errors for nonstandard finite element methods (FEM) of the clamped biharmonic plate problem based on piecewise quadratic polynomials, namely the nonconforming Morley FEM [26], the symmetric interior penalty discontinuous Galerkin FEM (dGFEM) [28], and the $C^0$ interior penalty method ($C^0$IP) [6], with respective solutions $u_{IM}$, $u_h$, and $u_{IP}$; Table 1 displays details of the respective schemes. For $F \in L^2(\Omega)$, dGFEM and hp-dGFEM for biharmonic and fourth-order problems, are extensively studied in [27, 28, 30, 31, 36, 37, 39].

For a general right-hand side $F \in H^{-2}(\Omega)$, the standard right-hand side $F(u_h)$ remains undefined for nonstandard finite element methods. A postprocessing procedure in [6] enables to introduce a new $C^0$IP method for right-hand sides in $H^{-2}(\Omega)$. In [41–43], the discrete test functions are transformed into conforming functions ($J$ is called smoother in those works) before applying the load functional and quasi-optimal energy norm.
Table 1. Overview of notation for four discrete schemes with discrete bilinear form (5.12)

| Schemes       | Notation          | Morley FEM | dGFEM  | C₀IP    | WOPSIP  |
|---------------|-------------------|------------|--------|---------|---------|
| Section reference | Section 3.2       | Section 7  | Section 8 | Section 10 |
| Vₕ            | M(T)              | P₂(T)      | S₂(T)  | P₂(T)   |
| Aₕ            | aₚw in (3.3)      | AₜₐG in (7.1) | Aₜ₈ in (8.1) | Aₜₐp in (10.2) |
| bₕ            | 0                 | −Θ J Jₜ in (6.2) | −Θ J Jₜ in (6.2) | 0       |
| cₕ            | 0                 | cₜₐG in (4.3) | cₜ₈ in (8.2) | cₜₐp in (10.1) |
| Iₕ : M(T) → Vₕ | id                | id         | Iₘ in (8.4) | id      |

estimates

\[ \|u - uₕ\|ₚw ≈ \min_{vₕ \in M(T)} \|u - vₕ\|ₚw, \quad \|u - uₜ₈\|ₜ₈ ≈ \min_{vₜ₈ \in IP(T)} \|u - vₜ₈\|ₜ₈ \]

are derived for the Morley FEM and C₀IP method.

The papers [41–43] discuss minimal conditions on a smoother for each problem, while this paper presents one smoother Jₘ for all schemes; the best-approximation for the dGFEM is a new result. The smoother Jₘ also allows a post-processing with a priori error estimates in weaker and piecewise Sobolev norms.

Table 1 summarizes the notation of spaces, bilinear forms, and an operator for the four second-order methods for the biharmonic problem detailed in Section 3.2 and in Sections 7, 8, and 10.

Contributions

The main contributions of this paper are

(a) the design and analysis of a generalized Morley interpolation operator Iₘ for piecewise smooth functions in \(H₂(T)\),
(b) the design of modified schemes for Morley FEM, dGFEM, C₀IP method, and a weakly over-penalized symmetric interior penalty (WOPSIP) method for the biharmonic problem for data in \(F \in H^{-2}(Ω)\),
(c) an abstract framework for the best-approximation property and weaker (piecewise) Sobolev norm estimates,
(d) a priori error estimates in (piecewise) Sobolev norms for the lowest-order nonstandard finite element methods for biharmonic plates,
(e) an extension of the results of [23] to an equivalence

\[ \|u - uₕ\|ₚw ≈ \|u - uₜ₈\|ₜ₈ ≈ \|u - uₜ₈\|ₜ₈ \approx \|(1 - Π₀)D²u\|_{L²(Ω)} \]

without data oscillations for the modified schemes,

(f) the proof of the best approximation for the modified dGFEM that extends [42] and Theorem 4.3 of [23].

Remark 1.1 (Medius analysis). The quasi-optimality of nonconforming and discontinuous Galerkin methods was established in the seminal paper [34] for the original method up to data oscillations for \(F \in L²(Ω)\). Arguments from a posteriori error analysis [44] give new insight in the consistency term from the Strang–Fix lemmas. The techniques in this paper circumvent any a posteriori error analysis and take advantage of the extra benefits of the companion operator J.

Remark 1.2 (Smother). The fundamental series of contributions [41–43] on the quasi-optimality concerns best-approximation for a modified scheme with \(Fₕ := F \circ J\) for a smoother J. Elementary algebra indicates a key identity (of (5.5) below) that is already mentioned in (5.15) of [6] and makes the source term in the consistency disappear.
Remark 1.3 (Extension to higher order). A (general) Morley interpolation allows for a simultaneous analysis of four lowest-order schemes, but appears to be restricted to piecewise quadratics at first glance. But the combination of $\mathcal{J}_l^{(h)}$ as an averaging smoother with higher-order bubble-smoothers shall enable applications to higher-order schemes as indicated in [42].

Remark 1.4 (Extension to 3D). Although the plate problem is intrinsic two-dimensional, there are threedimensional Morley finite elements with a recent companion operator [18] that guarantees the fundamental properties in 3D such that the abstract framework applies.

Organization

The remaining parts of this paper are organised as follows. Section 2 provides an abstract characterization of the best-approximation property that applies to the various applications considered in this and future papers [25]. Section 3 presents preliminaries, a nonconforming discretisation, introduces a novel generalized Morley interpolation operator for discontinuous functions, and states a best-approximation [16] result for nonconforming discretisations with data $F \in H^{-2}(\Omega)$. Section 4 proves a crucial equivalence result of two discrete norms for a piecewise $H^2(T)$ function, and proves approximation properties for the generalized Morley interpolation operator. Section 5 provides a framework for dG methods and the proof of a best-approximation property under a set of general assumptions. Section 6 develops the abstract result for a priori error estimates in weaker and piecewise Sobolev norms. Sections 7 and 8 recall the dG and $C^0$IP schemes and verify the assumptions of Sections 5 and 6 for the best-approximation result in the energy norm as well as weaker and piecewise Sobolev norms without data oscillations. The paper concludes with the equivalence (1.1) of errors in Section 9 and a proof of quasi-optimality up to penalty for the WOPSIP scheme in Section 10.

General notation

Standard notation of Lebesgue and Sobolev spaces, their norms, and $L^2$ scalar products applies throughout the paper such as the abbreviation $\| \cdot \|$ for $\| \cdot \|_{L^2(\Omega)}$. For real $s$, $H^s(\Omega)$ denotes the Sobolev space associated with the Sobolev–Slobodeckii semi-norm $\| \cdot \|_{H^s(\Omega)}$ [33]; $H^s(T) := H^s(\text{int}(T))$ abbreviates the Sobolev space with respect to the interior $\text{int}(T) \neq \emptyset$ of a (compact) triangle $T$. The closure of $D(\Omega)$ in $H^s(\Omega)$ is denoted by $H^s_0(\Omega)$ and $H^{-s}(\Omega)$ is the dual of $H^s_0(\Omega)$. The triple norm $\| \cdot \| := \| \cdot \|_{H^2(\Omega)}$ is the energy norm and $\| \cdot \|_{pw} := \| \cdot \|_{H^2(T)} := \| D^2_{pw} \cdot \|$ is its piecewise version with the piecewise Hessian $D^2_{pw}$. Given any function $v \in L^2(\omega)$, define the integral mean $\int_{\omega} v \, dx := 1/|\omega| \int_{\omega} v \, dx$; where $|\omega|$ denotes the area of $\omega$. The notation $A \lesssim B$ abbreviates $A \leq CB$ for some positive generic constant $C$, which depends only on $\Omega$ and the shape regularity of $T$; $A \approx B$ abbreviates $A \lesssim B \lesssim A$.

2. Prologue

This section characterizes the best-approximation property of a class of non-conforming finite element methods. The biharmonic problem is put in an abstract framework in real Hilbert spaces $X$ and $Y$ and a bounded bilinear form $a : X \times Y \to \mathbb{R}$ satisfying an inf-sup condition. Given a right-hand side $F \in Y^*$, the exact problem seeks $x \in X$ with

$$a(x, \bullet) = F \quad \text{in } Y.$$  

The discrete problem is put in an analog framework with finite-dimensional real Hilbert spaces $X_h$ and $Y_h$ and a bilinear form $a_h : X_h \times Y_h \to \mathbb{R}$. The discrete space $X_h$ (resp. $Y_h$) is not a subspace of $X$ (resp. $Y$) in general, but $X$ and $X_h$ (resp. $Y$ and $Y_h$) belong to one common bigger vector space that gives rise to the sum $\tilde{X} = X + X_h$ (resp. $\tilde{Y} = Y + Y_h$). It is not supposed that this is a direct sum, so the intersection $X \cap X_h$ (resp. $Y \cap Y_h$) may be non-trivial. We suppose that $\tilde{X}$ and $\tilde{Y}$ are real Hilbert spaces with (complete) subspaces $X, X_h$ and $Y, Y_h$. The linear and bounded map $Q \in L(Y_h; Y)$ links the right-hand side $F \in Y^*$ of the exact problem to the right-hand side $F_h := F \circ Q \in Y_h^*$ of the discrete problem. The map $Q$ is called smoother in [41–43] because...
it maps a (possibly) discontinuous function \( y_h \in Y_h \) to a smooth function \( Q y_h \) in applications. The resulting \textit{discrete problem} seeks \( x_h \in X_h \) with

\[
a_h(x_h, \bullet) = F(Q \bullet) \quad \text{in} \quad Y_h. \tag{2.1}
\]

We also suppose that the exact and discrete problems are well-posed and this means in particular that \( \dim X_h = \dim Y_h < \infty \) and that the bounded bilinear forms \( a \) and \( a_h \) satisfy inf-sup conditions with positive constants \( \alpha \) and \( \alpha_h \) and are non-degenerate such that the associated linear and bounded operators \( A \in L(X; Y^*) \) and \( A_h \in L(X_h; Y_h^*) \) are bijective; the associated linear operators are defined by \( A x := a(x, \bullet) \in Y^* \) for all \( x \in X \) and by \( A_h x_h := a_h(x_h, \bullet) \in Y_h^* \) for all \( x_h \in X_h \).

The general discussion in \cite{41–43}, leads to an optimal smoothing \( Q = \Pi_Y|_{Y_h} \) for the orthogonal projection \( \Pi_Y \in L(\hat{Y}) \) onto \( Y \). This is a global operation in general and hence infeasible for practical computations. Notice carefully that all examples in \cite{41–43} discuss \( Q \in L(Y_h; Y) \) with \( Qz = z \) for all \( z \in Y_h \cap Y \), abbreviated by

\[
Q = \text{id} \quad \text{in} \quad Y_h \cap Y. \tag{2.2}
\]

This paper introduces a smoother \( JIM \) for the discontinuous Galerkin schemes that satisfies (2.2) and is quasi-optimal in the following sense with a constant \( \Lambda_Q \geq 0 \) that is exclusively bounded in terms of the shape regularity of the underlying triangulations.

**Definition 2.1** (Quasi-optimal smoother). A linear bounded operator \( Q \in L(Y_h; Y) \) is called a quasi-optimal smoother if there exists some \( \Lambda_Q \geq 0 \) such that

\[
\| y_h - Q y_h \|_{Y_h} \leq \Lambda_Q \| y_h - y \|_{Y_h} \quad \text{for all} \quad y_h \in Y_h \quad \text{and all} \quad y \in Y. \tag{2.3}
\]

The proofs of Lemma 2.2 and 2.4 below rely on compactness arguments whence in the Appendix A, the constants \( \Lambda_P \) and \( \Lambda_Q \) depend on the discrete space. The point is that this paper designs a smoother in Section 4.3 with a constant that does not depend on the mesh-size.

**Lemma 2.2.** The operator \( Q \in L(Y_h; Y) \) is a quasi-optimal smoother if and only if (2.2) holds.

The (nonconforming) finite element method is characterized by the operator \( M \in L(X; X_h) \) that maps any \( x \in X \) to a right-hand side \( F := a(x, \bullet) \in Y^* \) and then to the solution \( M x := x_h = A_h^{-1}(Q^* F) \) to (2.1), i.e., \( M x := A_h^{-1}(a(x, Q \bullet)) \in X_h \) for all \( x \in X \), or, in operator form,

\[
M := A_h^{-1} Q^* A \in L(X; X_h).
\]

In other words, the subsequent diagram commutes.

\[
\begin{array}{ccc}
X & \xrightarrow{A} & Y^* \\
\uparrow & & \uparrow \\
\uparrow & & \uparrow \\
P & \xrightarrow{M} & Q^* \\
\downarrow & & \downarrow \\
X_h & \xrightarrow{A_h^{-1}} & Y_h^*
\end{array}
\]

This diagram also depicts some (linear and bounded) operator \( P : X_h \to X \) that will become a quasi-optimal smoother in the context of the best-approximation property of \( M \) below. A synonym to the best-approximation property of \( M \) is to say \( M \) is quasi-optimal in the following sense.
Definition 2.3 (Quasi-optimal). The above operator $M$ is said to be quasi-optimal if

$$\text{(QO)} \quad \exists C_{qo} > 0 \quad \forall x \in X \quad \|x - Mx\|_\Xi \leq C_{qo} \min_{x_h \in X_h} \|x - x_h\|_{\Xi}.$$

A first characterisation of (QO) has been given in [41] in terms of

$$M = \text{id} \in X_h \cap X. \quad (2.4)$$

Lemma 2.4 ([41]). Under the present notation, (QO) is equivalent to (2.4).

The above lemmas characterize $C_{qo}$ and $\Lambda_Q$ by a compactness argument and it remains to control $C_{qo}$ and $\Lambda_Q$ in terms of mesh-size independent bounds in applications. This paper designs in Section 4.3 a smoother in the spirit of [41–43] based on earlier work in the context of a posteriori error control [9, 12, 22] and adaptive mesh-refinement [14, 17–19]. The outcome is a quasi-optimal smoother $P \in L(X_h; X)$ with a constant $\Lambda_P$ that depends only on the shape regularity of the underlying finite element mesh and

$$\|x_h - P x_h\|_\Xi \leq \Lambda_P \|x_h - x\|_\Xi \quad \text{for all } x_h \in X_h \text{ and all } x \in X. \quad (2.5)$$

The proof of the following characterization of best-approximation shall be given in the Appendix A.

Theorem 2.5. Suppose $P \in L(X_h; X)$ and $\Lambda_P$ satisfy (2.5). Then (QO) is equivalent to the existence of $\Lambda_H > 0$ with

$$\text{(H)} \quad a_h(x_h, y_h) - a(P x_h, Q y_h) \leq \Lambda_H \|x_h - P x_h\|_\Xi \|y_h\|_\Psi \quad \text{for all } x_h \in X_h \text{ and } y_h \in Y_h.$$

In particular, if (H) holds, then (QO) follows with a constant $C_{qo}$ that depends solely on $\alpha_h$, $\Lambda_H$, $\Lambda_P$, $\|Q\|$, and $\|A\|$.

The next theorem presents a key estimate that is crucial for goal-oriented error control and duality arguments for weaker norm estimates. The proof and the dependence of contents are presented in the Appendix A. The motivation for (QO) is exemplified in Theorem 2.7 below.

Theorem 2.6. Suppose $P$ and $Q$ are quasi-optimal smoothers with (2.3)–(2.5) and suppose (QO). Then the existence of $\widehat{C}_{qo} > 0$ with

$$\widehat{\text{(QO)}} \quad a(x - PM x, y) \leq \widehat{C}_{qo} \|x - Mx\|_\Xi \|y - y_h\|_\Psi \quad \text{for all } x \in X, y \in Y, \text{ and } y_h \in Y_h$$

is equivalent to the existence of $\widehat{\Lambda}_H > 0$ with

$$\widehat{\text{(H)}} \quad a_h(x'_h, y_h) - a(P x'_h, Q y_h) \leq \widehat{\Lambda}_H \|x'_h - P x'_h\|_\Xi \|y_h\|_\Psi \quad \text{for all } x'_h \in X'_h, \text{ and } y_h \in Y_h.$$

In particular, if (H) holds, (QO) follows with a constant $\widehat{C}_{qo}$ that depends solely on $\alpha$, $\Lambda'_2$, $\Lambda_P$, and $\Lambda_Q$. The a priori error estimates in weaker Sobolev norms (weaker than the energy norm) are a corollary of Theorem 2.6 and the elliptic regularity, the latter is written in an abstract form by the assumption that $X_s$ and $Y_s$ are two Hilbert spaces with $X \subset X_s$ and $Y_s \subset Y$ such that

$$\text{(R)} \quad \exists C_{\text{reg}} > 0 \quad \forall F \in X'_s \quad \|A^{-\ast} F\|_{Y_s} \leq C_{\text{reg}} \|F\|_{X'_s}$$

for the solution $y := A^{-\ast} F \in Y_s \subset Y$ to $a(\bullet, y) = F \in X'_s \subset X'$.

Theorem 2.7 (Weak a priori). Under the assumptions of Theorem 2.6, (QO) and (R) imply

$$\|x - PM x\|_{X_s} \leq \widehat{C}_{qo} \|x - Mx\|_\Xi \quad \sup_{y \in Y_s} \inf_{y_h \in Y_h} \|y - y_h\|_\Psi \quad \text{for all } x \in X.$$
Proof. Given \( x - PMx \in X \subset X_s \), a corollary of the Hahn–Banach extension theorem leads to some \( F \in X_s^* \subset X^* \) with \( \|F\|_{X_s^*} \leq 1 \) in \( X_s^* \) and \( \|x - PMx\|_{X_s} = F(x - PMx) \). The dual solution \( y \in Y \) to \( F = a(\cdot, y) \in X^* \) satisfies (R) and (QO) leads to
\[
\|x - PMx\|_{X_s} = a(x - PMx, y) \leq C_{qo} \|x - Mx\|_X \|y - y_h\|_Y
\]
for any \( y_h \in Y_h \). This and \( \|y\|_Y \leq C_{reg} \|F\|_{X_s^*} \leq C_{reg} \) conclude the proof. \( \square \)

Example 2.8 (Standard). For the \( m \)-harmonic operator \( A = (-1)^m \Delta^m \) and \( X = H_0^m(\Omega) = Y \), (R) holds for \( X_s = H_0^{m-s}(\Omega) \), \( Y_s = H^{m+s}(\Omega) \) and \( 1/2 \leq s \leq 1 \), \( m = 1 \) or \( 2 \). Typical first-order approximation properties of the discrete finite element spaces result in
\[
\sup_{y \in Y_s} \inf_{y_h \in Y_h} \|y - y_h\|_Y = O(h_{max}^a)
\]
in terms of the maximal mesh-size \( h_{max} \) of the underlying finite element mesh.

Remark 2.9 (Best-approximation constant). The paper [41] gives a formula for the best-approximation constant \( C_{qo} \) for some slightly simpler problem in one Hilbert space.

Remark 2.10 (Injective smoother). Under the above notation \( Q \in L(Y_h;Y) \) is injective if and only if \( M \in L(X;X_h) \) is surjective [41]. Then there exists a right-inverse \( P \in L(X_h;X) \) to \( M \) and \( (H) \) holds with \( \Lambda_H = 0 \) (this follows with the arguments of the proof of Theorem 2.7 for \( P' \) that is in fact a quasi-optimal smoother owing to (A.5)). Consequently, the discrete scheme is equivalent to a conforming Petrov–Galerkin scheme.

Remark 2.11 (Non injective smoother). In case \( Q \in L(Y_h;Y) \) is not injective, the discrete problem may reduced to the range \( X_h' := \mathcal{R}(M) \) of \( M \) and the orthogonal complement \( Y_h'' \) of the kernel of \( Q \) in \( Y_h \). However, the explicit computation of the reduced discrete spaces \( X_h' \) and \( Y_h'' \) may be costly and hence this paper outlines a general analysis that allows non-injective quasi-optimal smoothers.

Example 2.12 (Smoother for Morley). For the standard Morley interpolation operator \( I_M : H_0^2(\Omega) \rightarrow M(T) \) and a companion operator \( J : M(T) \rightarrow H_0^2(\Omega) \) (cf., Lem. 3.7 below for details) the smoother \( Q = JI_M \) is injective because \( J \) is a right-inverse of \( I_M \).

Example 2.13 (Smoother for dG). This paper advertises a smoother \( Q := JI_M \) for a (generalized) Morley interpolation \( I_M : (P_2(T) + H_0^2(\Omega)) \rightarrow M(T) \) (cf., (3.5) below for details) followed by a companion operator \( J \) from the previous example for the dG FEM. Then \( \dim P_2(T) = 6 \mid T \) is strictly larger than \( \dim M(T) = |\mathcal{V}(\Omega)| + |\mathcal{E}(\Omega)| \); whence \( Q \) cannot be injective.

The situation for the \( C^0 \) IP with the discrete space \( S_2(T) \) (of the same dimension as \( M(T) \)) is more involved and is discussed in more details in Section 8 below.

3. Preliminaries

3.1. Continuous model problem

Suppose \( u \in V := H_0^2(\Omega) \) solves the biharmonic equation \( \Delta^2 u = F \) for a given right-hand side \( F \in V^* \equiv H^{-2}(\Omega) \) in a planar bounded Lipschitz domain \( \Omega \) with polygonal boundary \( \partial \Omega \). The weak form of this equation reads
\[
a(u,v) = F(v) \quad \text{for all } v \in V
\] (3.1)
with the scalar product \( a(v,w) := \int_{\Omega} D^2v : D^2w \, dx \) for all \( v,w \in V \). It is well known that (3.1) has a unique solution \( u \) and elliptic regularity [1,3,32,38] holds in the sense that \( F \in H^{-s}(\Omega) \) implies \( u \in V \cap H^{4-s}(\Omega) \) for
3.2. Nonconforming discretisation

Throughout the rest of this article, the following notations are adopted. Let $\mathcal{T}$ denote a shape regular triangulation of the polygonal Lipschitz domain into compact triangles. Associate its piecewise constant mesh-size $h_T \in P_0(T)$ with $h_T := h_T|_T := \text{diam}(T) \approx |T|^{1/2}$ in any triangle $T \in \mathcal{T}$ of area $|T|$ and its maximal mesh-size $h_{\text{max}} := \max h_T$. Let $\mathcal{V}$ (resp. $\mathcal{V}(\Omega)$ or $\mathcal{V}(\partial \Omega)$) denote the set of all (resp. interior or boundary) vertices in $\mathcal{T}$. Let $\mathcal{E}$ (resp. $\mathcal{E}(\Omega)$ or $\mathcal{E}(\partial \Omega)$) denote the set of all (resp. interior or boundary) edges. The length of an edge $E$ is denoted by $h_E$. Let $\Pi_k$ denote the $L^2(\Omega)$ orthogonal projection onto the piecewise polynomials $P_k(T) := \{v \in L^2(\Omega) : \forall T \in \mathcal{T}, v|_T \in P_k(T)\}$ of degree at most $k \in \mathbb{N}_0$. Let the Hilbert space $H^1(\Omega) \equiv \prod_{T \in \mathcal{T}} H^1(T)$.

Define the jump $[\varphi]_E := \varphi|_{T_+} - \varphi|_{T_-}$ and the average $\langle \varphi \rangle_E := \frac{1}{2}(\varphi|_{T_+} + \varphi|_{T_-})$ across the interior edge $E = \partial T_+ \cap \partial T_- \in \mathcal{E}(\Omega)$ of $\varphi \in H^1(T)$ of the adjacent triangles $T_+$ and $T_- \in \mathcal{T}$ in an order such that the unit normal vector $\nu_{T_+}|_E = \nu_E = -\nu_{T_-}|_E$ along the edge $E$ has a fixed orientation and points outside $T_+$ and inside $T_-$. $\nu_T$ is the outward unit normal of $T$ along $\partial T$. The edge-patch $\omega(E) := \text{int}(T_+ \cup T_-)$ of the interior edge $E = \partial T_+ \cap \partial T_- \in \mathcal{E}(\Omega)$ is the interior of union $T_+ \cup T_-$ of the neighboring triangles $T_+$ and $T_-$. Extend the definition of the jump and the average to an edge $E \in \mathcal{E}(\partial \Omega)$ on the boundary by $[\varphi]|_E := \varphi|_E$ and $\langle \varphi \rangle_E := \varphi|_E$ owing to the homogeneous boundary conditions.

The nonconforming Morley finite element space [26] reads

$$M'(T) := \left\{ v_M \in P_2(T) \mid \begin{array}{l} v_M \text{ is continuous at the vertices and its normal derivatives} \\ \nu_E \cdot \nabla_{pw} v_M \text{ are continuous at the midpoints of interior edges} \end{array} \right\},$$

$$M(T) := \left\{ v_M \in M'(T) \mid \begin{array}{l} v_M \text{ vanishes at the vertices of } \partial \Omega \text{ and its normal derivatives} \\ \nu_E \cdot \nabla_{pw} v_M \text{ vanish at the midpoints of boundary edges} \end{array} \right\}.$$

Figure 1a depicts the degrees of freedom of the Morley finite element

$$\left(T, P_2(T), (\delta_z : z \in \mathcal{V}(T)) \cup \int_E \nu_E \cdot \mathbf{n} : E \in \mathcal{E}(T) \right)$$

(in the sense of Ciarlet) in the triangle $T$ with set of vertices $\mathcal{V}(T)$ and set of edges $\mathcal{E}(T)$.
The semi-scalar product $a_{pw}$ is defined by the piecewise differential operator $D^2_{pw}$ and

$$a_{pw}(v_{pw}, w_{pw}) := \sum_{T \in \mathcal{T}} D^2v_{pw} : D^2w_{pw} \, dx \quad \text{for all } v_{pw}, w_{pw} \in H^2(T).$$

(3.3)

It induces a piecewise $H^2$ seminorm $||| \cdot |||_{pw}$ that is also a norm in $M(T)$. Then $(M(T), a_{pw})$ is a (finite-dimensional) Hilbert space so that, given any $F_h \in M(T)^*$, there exists a unique discrete solution $u_M \in M(T)$ to

$$a_{pw}(u_M, v_M) = F_h(v_M) \quad \text{for all } v_M \in M(T).$$

(3.4)

3.3. Interpolation of discontinuous functions

**Lemma 3.2** (Interpolation estimates I [8, 10]). The Morley interpolation operator $I_M : V \rightarrow M(T)$ is defined by $(I_M v)(z) = v(z)$ and $\int_E \frac{\partial I_M v}{\partial n_E} \, ds = \int_E \frac{\partial v}{\partial n_E} \, ds$ for any $z \in V(\Omega)$ and $E \in \mathcal{E}(\Omega)$. It satisfies

(a) the integral mean property of the Hessian, $D^2_{pw} I_M = \Pi_0 D^2$;
(b) $\sum_{m=0}^2 h_T^{m-2} |v - I_M v|_{H^m(T)} \leq 2 \| (1 - \Pi_0) D^2 v \|_{L^2(T)}$ for all $v \in H^2(T)$ and any $T \in \mathcal{T}$,
(c) $\| v - I_M v \|_{pw} \lesssim h_T^{s+\frac{s}{2}} \| v \|_{H^{s+\frac{s}{2}}(\Omega)}$ for all $v \in H^{s+\frac{s}{2}}(\Omega)$ and all $0 \leq s \leq 1$.

A reformulation of Lemma 3.2a is the best-approximation property

$$a_{pw}(v - I_M v, w_2) = 0 \quad \text{for all } v \in V \text{ and all } w_2 \in P_2(T).$$

(3.5)

A reformulation of Lemma 3.2b is the existence of a universal constant $\kappa > 0$ with

$$\| h_T^{-2}(v - I_M v) \| \leq \kappa \| v - I_M v \|_{pw} \quad \text{for all } v \in V.$$  

(3.6)

(In fact, $\kappa = 0.25745784465$ from [10] is independent of the shape of the triangle $T$.)

**Remark 3.3** (Pythagoras). The functions $v_{pw}, w_{pw} \in H^2(T) := \{ v_{pw} \in L^2(\Omega) : \forall T \in \mathcal{T}, \ v_{pw}|_T \in H^2(T) \}$ are orthogonal iff $a_{pw}(v_{pw}, w_{pw}) = 0$ holds and then the Pythagoras theorem leads to

$$\| v - w_M \|_{pw}^2 = \| v - I_M v \|_{pw}^2 + \| w_M - I_M v \|_{pw}^2$$

(3.7)

for all $v \in V$ and $w_M \in M(T)$. In particular, $\| v - I_M v \|_{pw} = \min_{v_2 \in P_2(T)} \| v - v_2 \|_{pw}$. 

\[ \text{Figure 1. (a) Morley (left) and (b) HCT (right) finite element.} \]
**Definition 3.4** (local Morley interpolation). Given any \( T \in \mathcal{T} \) and \( v_{pw} \in H^2(T) \), the (local) Morley interpolation \( I_M^p v_{pw} |_T \in P_2(T) \) is defined by the degrees of freedom of the Morley finite element such that, for all \( z \in \mathcal{V}(T) \) and for all \( E \in \mathcal{E}(T) \),

\[
(I_M^p v_{pw} - v_{pw})|_T(z) = 0 \quad \text{and} \quad \int_E (\partial (I_M^p v_{pw} - v_{pw})|_T / \partial v_E) \, ds = 0.
\]

The Morley interpolation allows for an extension (still denoted by \( I_M \) to piecewise \( H^2 \) functions in \( H^2(\Omega) = \prod_{T \in \mathcal{T}} H^2(T) \) by averaging the degrees of freedom.

**Definition 3.5** (Morley interpolation). Given any \( v_{pw} \in H^2(\Omega) \), define \( I_M v_{pw} := v_M \in M(\Omega) \) by the degrees of freedom as follows. For any interior vertex \( z \in \mathcal{V}(\Omega) \) with set of attached triangles \( T(z) \) that has cardinality \( |T(z)| \in \mathbb{N} \) and any interior edge \( E = \partial T_+ \cap \partial T_- \in \mathcal{E}(\Omega) \) and its mean value operator \( \langle \bullet \rangle_E \) (the arithmetic mean of the two traces from the triangles \( T_+ \) and \( T_- \in \mathcal{T} \) along their common edge \( E = \partial T_+ \cap \partial T_- \)), set

\[
v_M(z) := |T(z)|^{-1} \sum_{T \in T(z)} (v_{pw}|_T)(z) \quad \text{and} \quad \int_E \frac{\partial v_M}{\partial v_E} \, ds := \int_E \left( \frac{\partial v_{pw}}{\partial v_E} \right) \, ds.
\]

(The remaining degrees of freedom at vertices and edges on the boundary are zero for homogeneous boundary conditions.)

**Remark 3.6** (Standard Morley interpolation vs. Def. 3.5). The interpolation operator \( I_M \) of Definition 3.5 extends that of standard Morley interpolation operator in the sense that the two definitions coincide for functions in \( H^2_0(\Omega) \). This justifies the use of the same symbol \( I_M \).

### 3.4. Companion operator and best-approximation for the Morley FEM

A conforming finite-dimensional subspace of \( H^2_0(\Omega) \) is provided by the Hsieh–Clough–Tocher (HCT) FEM ([26], Chap. 6). For any \( T \in \mathcal{T} \), let \( K(T) := \{ E : E \in \mathcal{E}(T) \} \) denote the triangulation of \( T \) into three sub-triangles \( T_E := \text{conv}\{E, \text{mid}(T)\} \) with edges \( E \in \mathcal{E}(T) \) and common vertex \( \text{mid}(T) \) depicted in Figure 1b. Then,

\[
\text{HCT}(T) := \{ v \in H^2(\Omega) : v|_T \in P_3(K(T)) \text{ for all } T \in \mathcal{T} \}.
\]

The degrees of freedom in a triangle \( T \in \mathcal{T} \) are the nodal values \( \psi(z) \) and its derivative \( \nabla \psi(z) \) of the function \( \psi \in \text{HCT}(T) \) at any vertex \( z \in \mathcal{V}(T) \) and the values \( \partial \psi / \partial v_E(\text{mid}(E)) \) of the normal derivatives at the midpoint \( \text{mid}(E) \) of any edge \( E \in \mathcal{E}(T) \).

**Lemma 3.7** (Right-inverse [17, 29, 41]). There exists a linear map \( J : M(\Omega) \to (\text{HCT}(T) + P_8(T)) \cap H^2_0(\Omega) \) and a constant \( \Lambda_J \) (that exclusively depends on the shape regularity of \( T \)) such that any \( v_M \in M(\Omega) \) satisfies (a)–(e).

(a) \( Jv_M(z) = v_M(z) \) for any \( z \in \mathcal{V} \);
(b) \( \nabla(Jv_M)(z) = |T(z)|^{-1} \sum_{T \in T(z)} (\nabla v_M|_T)(z) \) for \( z \in \mathcal{V}(\Omega) \);
(c) \( \int_E \frac{\partial Jv_M}{\partial v_E} \, ds = \int_E \frac{\partial v_M}{\partial v_E} \, ds \) for any \( E \in \mathcal{E} \);
(d) \( \|v_M - Jv_M\|_{pw} \leq \Lambda_J \min_{v \in \mathcal{V}} \|v_M - v\|_{pw} \);
(e) \( v_M - Jv_M \perp P_2(T) \) in \( L^2(\Omega) \).

The operator \( J \) of Lemma 3.7 with (a)–(c) is a right-inverse for \( I_M : V \to M(\Omega) \), i.e.,

\[
I_M J = \text{id} \text{ in } M(\Omega).
\]
Examples are provided in [17, 29, 41]. For earlier references in the literature, see [5, 13, 20]. A right-inverse with benefits like (d) and (e) is called companion operator and [17] defines $J : M(T) \to V$ so that (a)–(e) of Lemma 3.7 hold (cf., in particular [17], Lem. 5.1 for the analysis of (d) and (e)).

Given $F \in L^2(\Omega)$, we may choose $F_h \equiv F$ in the discrete scheme (3.4); but otherwise $F_h = F \circ J$ is the option throughout this paper; other choices are proposed in [6, 42]. Given any Lebesgue function $F \in \mathcal{L}^2(\Omega)$ with its $L^2$ projection $\Pi_2F$ onto $P_2(T)$, define its oscillations $\text{osc}_2(F, T) := \|h_T^2(F - \Pi_2F)\|$.  

**Theorem 3.8** (Best-approximation up to data approximation [23, 34]). The constant $C_1 := \max\{\kappa\Lambda_J, 1 + \Lambda_J\}$, the solution $u \in V$ to (3.1) with $F \in L^2(\Omega)$, and the solution $u_M \in M(T)$ to (3.4) with $F_h \equiv F$ satisfy $C_1^{-1}\|u - u_M\|_\text{pw} \leq \|u - I_Mu\|_\text{pw} + \text{osc}_2(F, T)$.

The discrete scheme (3.4) requires a discrete right-hand side $F_h$ for a general $F \in H^{-2}(\Omega)$. The evaluation of $F_h := F \circ J$ is feasible with $F_h(v_M) := F(Jv_M)$ for all $v_M \in M(T)$ and the (modified) nonconforming scheme seeks the solution $u_M \in M(T)$ to

$$a_{\text{pw}}(u_M, v_M) = F(Jv_M) \quad \text{for all } v_M \in M(T). \quad (3.10)$$

Let $\Lambda_0$ denote the norm of $1 - J$, where the right-inverse $J \in L(M(T); V)$ is regarded as a linear map between $M(T)$ and $V$,

$$\Lambda_0 := \sup_{v_M \in M(T) \setminus \{0\}} \frac{\|v_M - Jv_M\|_\text{pw}}{\|v_M\|_\text{pw}} \leq \Lambda_J. \quad (3.11)$$

**Theorem 3.9** (Best-approximation [16, 43]). The solution $u \in V$ to (3.1) with $F \in \mathcal{L}^\ast$ and the solution $u_M \in M(T)$ to (3.10) satisfy $\|u - u_M\|_\text{pw} \leq \sqrt{1 + \Lambda_0^2}\|u - I_Mu\|_\text{pw}$. The constant $\sqrt{1 + \Lambda_0^2}$ is optimal.

**Remark 3.10** (Extra orthogonality in Lem. 3.7c). The $L^2$ orthogonality in Lemma 3.7e allows control over dual norm estimates of the form $\|v_M - Jv_M\|_{H^{-s}(\Omega)} \lesssim \|h_T^2(v_M - Jv_M)\|$ for $0 \leq s \leq 2$. This is critical in eigenvalue analysis or problems with low-order terms; for e.g., in [14, 17]. The $L^2$ orthogonality in Lemma 3.7e also allows a direct proof of Theorem 3.8 that circumvents the a posteriori error analysis of the consistency term as part of the medius analysis [34]. Notice that the proof of the best-approximation of Theorem 3.9 for the modified scheme does not require the $L^2$ orthogonality in Lemma 3.7e.

**Remark 3.11** (Minimal assumptions on the smoother). The series of papers [41–43] addresses the question on the minimal assumptions on the smoother (partly as a right inverse only). This paper utilizes a smoother $J$ with the properties of Lemma 3.7a–d.

The point in the subsequent example is that the smoother $JI_M$ may be more costly than averaging in other examples but it is at almost no extra costs for the case of point forces, which are of practical importance in civil engineering.

**Example 3.12** (Point forces). Let $m$ denote the point forces in the right-hand side, i.e., let

$$F = \sum_{j=1}^{m} \alpha_j \delta_{a_j}, \quad (3.12)$$

the triangulation can be adopted such that the concentration point $a_j$ becomes a vertex in the triangulation. The right-inverse property of $I_M$ displays that $(JI_Mv_M)(z) = v_M(z)$ holds at any vertex $z \in V$ and for any Morley function $v_M \in M(T)$. Hence the evaluation of the modified right-hand side $F_h := F \circ J$ leads for (3.12) to $F_h v_M = \sum_{j=1}^{m} \alpha_j v_M(a_j)$. The averaging of $I_M$ in Definition 3.5 shows in the more general case $V_h \subset P_2(\Omega)$ that $F_h := F \circ JI_M$ leads to $F_h v_M = \sum_{j=1}^{m} \alpha_j / |T(a_j)| \sum_{T \in T(a_j)} (v_h(T)) (a_j)$. The same formula applies to other smoothers like the enrichment in [6, 41–43].
4. Interpolation of Piecewise \( H^2 \) Functions

4.1. Equivalent norms

The Hilbert space \( H^2(T) \equiv \prod_{T \in \mathcal{T}} H^2(T) \) is endowed with a norm \( \| \bullet \|_h \) from [23] defined by

\[
\|v_{pw}\|_h^2 := \|v_{pw}\|_{pw}^2 + j_h(v_{pw})^2 \quad \text{for all } v_{pw} \in H^2(T).
\]  

(4.1)

The homogeneous boundary conditions in \( H_0^2(\Omega) \) are included in the the jump contributions

\[
j_h(v_{pw})^2 := \sum_{E \in \mathcal{E}} \sum_{z \in \mathcal{V}(E)} h_E^2 \left| [v_{pw}]_E(z) \right|^2 + \sum_{E \in \mathcal{E}} \left| \int_E \frac{\partial v_{pw}}{\partial n_E} \right| E \ ds \]  

(4.2)

by \([v_{pw}]_E(z) = v_{pw} \mid_\omega(E)(z)\) for \( z \in \mathcal{V}(\partial \Omega) \) and \( \frac{\partial v_{pw}}{\partial n_E} |_E = \frac{\partial v_{pw}}{\partial n_E} |_E \) for \( E \in \mathcal{E}(\partial \Omega) \) at the boundary with jump partner zero owing to the homogeneous boundary conditions in (3.1).

The discontinuous Galerkin schemes of [2,28] are associated with a another family of norms \( \| \bullet \|_{dG} \) depending on the two positive parameters \( \sigma_1, \sigma_2 > 0 \) in the semi-norm scalar product

\[
c_{dG}(v_{pw}, w_{pw}) := \sum_{E \in \mathcal{E}} \frac{\sigma_1}{h_E^2} \left( \int_E [v_{pw}]_E [w_{pw}]_E \ ds + \frac{\sigma_2}{h_E^2} \left( \int_E \frac{\partial v_{pw}}{\partial n_E} \right)_E \left( \frac{\partial w_{pw}}{\partial n_E} \right)_E \ ds \right) \]

(4.3)

for all \( v_{pw}, w_{pw} \in H^2(T) \). The DG norm \( \| \bullet \|_{dG} \) is the square root of

\[
\|v_{pw}\|_{dG}^2 := \|v_{pw}\|_{pw}^2 + c_{dG}(v_{pw}, v_{pw})
\]

(4.4)

for all \( v_{pw} \in H^2(T) \). It depends on the parameters \( \sigma_1, \sigma_2 > 0 \) and so do all constants in the sequel; in particular those suppressed in the abbreviations \( \lesssim \) and \( \approx \). The conditions on the ellipticity of the scheme in Lemma 7.1 below will assert that \( \sigma_1 \) and \( \sigma_2 \) are sufficiently large. The analysis of this paper assumes this and simplifies the notation \( \sigma_1 \approx 1 \approx \sigma_2 \).

One result in Theorem 4.1 of [23] shows that \( \| \bullet \|_h \approx \| \bullet \|_{dG} \) in \( H^2(\Omega) + P_2(\mathcal{T}) \); but the two norms are equivalent in the larger vector space \( H^2(T) \).

**Theorem 4.1 \((\| \bullet \|_h \approx \| \bullet \|_{dG})\).** The function \( \| \bullet \|_h \) from (4.1) and \( \| \bullet \|_{dG} \) from (4.4) define norms in \( H^2(T) \) with

\[
\|v_{pw}\|_h \approx \|v_{pw}\|_{dG} \sum_{m=0}^{2} |h_T^{-m-2} v_{pw}|_{H^m(T)} \quad \text{for all } v_{pw} \in H^2(T).
\]

(4.5)

**Remark 4.2 \((\{j_h = 0\} \cap P_2(\mathcal{T}) = M(\mathcal{T}))\).** For any \( v_2 \in P_2(\mathcal{T}) \), the condition \( j_h(v_2) = 0 \) is equivalent to \( v_2 \in M(\mathcal{T}) \). (This follows from the definitions of \( M(\mathcal{T}) \) and \( j_h \).)

**Proof of \( \| \bullet \|_h \lesssim \| \bullet \|_{dG} \).** The (possibly discontinuous) piecewise affine interpolation \( v_1 \in P_1(\mathcal{T}) \) of \( v_{pw} \in H^2(T) \) is defined by nodal interpolation \( v_1 \mid_T(z) = v_{pw} \mid_T(z) \) at the three vertices \( z \in \mathcal{V}(T) \) in each triangle \( T \in \mathcal{T} \). It is well known from standard finite element interpolation [4,6,26] that the error \( w := v_{pw} - v_1 \in H^2(T) \) satisfies

\[
\sum_{m=0}^{2} h_T^{-m-2} |w|_{H^m(T)} \lesssim |v_{pw}|_{H^2(T)}
\]

(4.5)

for each triangle \( T \in \mathcal{T} \) with explicit constants [21] that exclusively depend on the maximal angle in the triangulation. The nodal interpolation implies \([v_{pw}]_E(z) = [v_1]_E(z)\) at each vertex \( z \in \mathcal{V}(E) \) of an edge \( E \in \mathcal{E} \). Since \([v_1]_E \) is an affine function along the edge \( E \in \mathcal{E} \), an inverse estimate shows

\[
h_E/6 \sum_{z \in \mathcal{V}(E)} \left| [v_1]_E(z) \right|^2 \leq \left\| [v_1]_E \right\|_{L^2(E)}^2 \leq 2 \left\| [v_{pw}]_E \right\|_{L^2(E)}^2 + 2 \left\| [w]_E \right\|_{L^2(E)}^2
\]

(4.6)
with a triangle inequality in the last step for \( w = v_{pw} - v_1 \). (The constant \( h_E / 6 \) in the first inequality of (4.6) stems from the eigenvalues \( h_E / 2 \) and \( h_E / 6 \) of the 2 \( \times \) 2 mass matrix of piecewise linear functions in 1D.) This implies an estimate for the first term of the definition of \( j_h(v_{pw}) \):

\[
\sum_{E \in \mathcal{E}} \sum_{z \in \mathcal{V}(E)} h_E^{-2} ||v_{pw}||_E(z)^2 \leq 12 \sum_{E \in \mathcal{E}} h_E^{-2} \left( ||v_{pw}||_E^2 + ||w||_E^2 \right).
\]

A typical contribution \( (\int_E \partial v_{pw} / \partial v_E \, ds)^2 \) for the second term (in the definition of \( j_h \)) is controlled with a Cauchy inequality by \( h_E^{-1} ||\partial v_{pw} / \partial v_E||_E^2 \). This results in

\[
j_h(v_{pw})^2 \leq \sum_{E \in \mathcal{E}} h_E^{-1} \left( h_E^{-2} \left( ||v_{pw}||_E^2 + ||w||_E^2 \right) + ||\partial v_{pw} / \partial v_E||_E^2 \right).
\]

A triangle inequality \( ||w||_E^2 \leq ||w||_{T_+}^2 + ||w||_{T_-} \) for an interior edge \( E = \partial T_+ \cap \partial T_- \in \mathcal{E}(\Omega) \) shared by the two triangles \( T_\pm \in \mathcal{T} \) plus trace inequalities on \( T_\pm \) show

\[
h_E^{1/2} ||w||_E^2 \lesssim ||w||_{L^2(E)} + h_E ||\nabla_{pw} w||_{L^2(E)} \lesssim h_E^{1/2} ||D_{pw} v_{pw}||_{L^2(E)} \tag{4.7}
\]

with (4.5) in the end. The omission of \( T_- \) in the above arguments for an edge \( E \in \mathcal{E}(\partial \Omega) \) on the boundary provide (4.7) with \( \omega(E) = T_+ \).

This and the finite overlap show \( \sum_{E \in \mathcal{E}} h_E^{-3} ||w||_E^2 \lesssim \sum_{E \in \mathcal{E}} h_E^{-3} ||v_{pw}||_E^2 \). In conclusion,

\[
j_h(v_{pw})^2 \lesssim ||v_{pw}||_{\mathcal{H}_E}^2 + \sum_{E \in \mathcal{E}} h_E^{-3} ||v_{pw}||_E^2 + \sum_{E \in \mathcal{E}} h_E^{-1} ||\partial v_{pw} / \partial v_E||_E^2 \lesssim ||v_{pw}||_{\mathcal{H}_E}^2.
\]

The upper bound in the latter estimate is \( ||v_{pw}||_{\mathcal{H}_E}^2 \) up to the weights \( \sigma_1 \approx 1 \approx \sigma_2 \).

*Proof of \( ||\bullet||_{\mathcal{H}_E} \leq \sum \bullet \ ||\bullet||_h \).* Recall the piecewise affine interpolation \( v_1 \in P_1(T) \) of \( v_{pw} \in H^2(T) \) and \( w := v_{pw} - v_1 \in H^2(T) \) with (4.5) from the previous part of the proof. Standard trace inequalities as in (4.7) for the first term (and an analog for the second term \( h_E^{-1/2} ||\partial w / \partial v_E||_E^2 \)) for \( E \in \mathcal{E} \) provide

\[
h_E^{-3/2} ||w||_E^2 + h_E^{-1/2} ||\partial w / \partial v_E||_E^2 \lesssim ||D_{pw} v_{pw}||_{L^2(E)} \tag{4.8}
\]

This and triangle inequalities result in

\[
h_E^{-3/2} ||v_{pw}||_E^2 + h_E^{-1/2} ||\partial v_{pw} / \partial v_E||_E^2 \lesssim h_E^{-3/2} ||v_1||_E^2 + h_E^{-1/2} ||\partial v_1 / \partial v_E||_E^2 + ||D_{pw} v_{pw}||_{L^2(E)}.
\]

The constant factor 1/2 in the upper bound of the first subsequent inequality (displayed as 2 in the lower bound) stems from the eigenvalues \( h_E / 2 \) and \( h_E / 6 \) of the 2 \( \times \) 2 mass matrix of piecewise linear functions in 1D,

\[
2h_E^{-3} ||v_1||_E^2 \leq h_E^{-2} \sum_{z \in \mathcal{V}(E)} ||v_1(z)||^2 = h_E^{-2} \sum_{z \in \mathcal{V}(E)} ||v_{pw}(z)||^2
\]

with the nodal interpolation property \( v_1|_T(z) = v_{pw}|_T(z) \) for \( z \in \mathcal{V}(T), T \in \mathcal{T} \), in the last step. The jump \( ||\partial v_1 / \partial v_E||_E \) is constant along the edge \( E \) and so

\[
h_E^{-1/2} ||\partial v_1 / \partial v_E||_E^2 = \int_E ||\partial v_1 / \partial v_E||_E^2 \, ds \leq \int_E ||\partial v_{pw} / \partial v_E||_E^2 \, ds + \int_E ||\partial w / \partial v_E||_E^2 \, ds
\]
with a triangle inequality in the last step. A Cauchy inequality $\|\nabla v_{pw}\|_{L^1(E)} \leq h_E^{1/2} \|\nabla w_{pw}\|_{L^2(E)}$ and a trace inequality show (as above in (4.8)) that
\[
\left|\int_E \left[ \partial w / \partial \nu_E \right]_E ds \right| \leq h_E^{-1/2} \left\| \left[ \partial w / \partial \nu_E \right]_E \right\|_{L^2(E)} \lesssim \left\| D_{pw}^2 v_{pw} \right\|_{L^2(\omega(E))}.
\]
The combination of all aforementioned estimates reads
\[
h_E^{-3} \left\| [v_{pw}]_E \right\|_{L^2(E)}^2 + h_E^{-1} \left\| \partial v_{pw} / \partial \nu_E \right\|_{L^2(E)}^2 \lesssim \left\| D_{pw}^2 v_{pw} \right\|_{L^2(\omega(E))}^2 + h_E^{-2} \sum_{z \in \mathcal{V}(E)} \left\| [v_{pw}]_E(z) \right\|^2
\]
\[
+ \int_E \left| \partial v_{pw} / \partial \nu_E \right|_E ds \right|^2.
\]
The sum of all those estimates over $E \in \mathcal{E}$ plus $\| v_{pw} \|_{L^2}^2$ leads to an estimate with the lower bound $\| v_{pw} \|_{H^2}^2$ up to the weights $\sigma_1 \approx 1 \approx \sigma_2$. The finite overlap of the edge-patches ($\omega(E) : E \in \mathcal{E}$) shows that the resulting upper bound is $\lesssim \| v_{pw} \|_h$.

**Proof of the upper bound.** The proof of the asserted inequality starts with triangle inequalities for the jumps of $v_{pw} \in H^2(T)$ and the shape regularity for $h_E \approx h_T$ for $E \in \mathcal{E}(T)$. This and a Cauchy inequality $\|\nabla v_{pw}\|_{L^1(E)} \leq h_E^{-2} \|\nabla v_{pw}\|_{L^2(E)}$ lead to
\[
\sum_{E \in \mathcal{E}(T)} h_T^{-2} \sum_{z \in \mathcal{V}(E)} \left| (v_{pw}|T)(z) \right|^2 + h_T^{-1} \sum_{E \in \mathcal{E}(T)} \left\| \nabla v_{pw} \right\|_{L^2(E)}^2
\]
\[
\sum_{E \in \mathcal{E}(T)} \left( h_T^{-3} \left\| v_{pw} \right\|_{L^2(\partial T)}^2 + h_T^{-2} \left\| \nabla v_{pw} \right\|_{L^2(\partial T)}^2 \right) \lesssim \sum_{m=0}^{\infty} |h_T^m - 2 v_{pw}|_{H^m(T)}^2
\]
with standard trace inequalities on $\partial T$ for $v_{pw}$ and $\nabla v_{pw}$ in the last step. The right-hand side is $\sum_{m=0}^{\infty} |h_T^m - 2 v_{pw}|_{H^m(T)}^2$ as asserted. The remaining details are omitted for brevity.

### 4.2. Interpolation errors

The interpolation error estimates are summarised in one theorem.

**Theorem 4.3 (Interpolation).** Any $v_{pw} \in H^2(T)$ and its Morley interpolation $I_M v_{pw} \in M(T)$ from Definition 3.5 satisfy
\[(a) \sum_{m=0}^{\infty} |h_T^{-m}(v_{pw} - I_M v_{pw})|_{H^m(T)} \lesssim \left\| (1 - \Pi_0) D_{pw}^2 v_{pw} \right\| + J_h(v_{pw}) \lesssim \| v_{pw} \|_h;
\[(b) \sum_{m=0}^{\infty} \left| h_T^{-m}(v_{pw} - I_M v_{pw}) \right|_{H^m(T)} \approx \min_{w_M \in M(T)} \| v_{pw} - w_M \|_h \approx \min_{w_M \in M(T)} \sum_{m=0}^{\infty} |h_T^{-m}(v_{pw} - w_M)|_{H^m(T)}.
\]

**Proof of (a).** The first step reduces the analysis to piecewise quadratic functions by the piecewise Morley interpolation $I_M^{loc}$. Definition 3.4 shows $\int_E \nabla (I_M^{loc} v_{pw} - v_{pw}) |T| ds = 0$ for an edge $E \in \mathcal{E}(T)$ of the triangle $T$ and therefore $D^2(I_M^{loc} v_{pw}) |T| = \Pi_0 D^2 v_{pw} |T|$ a.e. in $T \in \mathcal{T}$. Notice that the piecewise defined Morley interpolation
The observation is that the left-hand side of (4.9) involves the polynomial 
\( \frac{1}{T} T T T \) for all explicit formulas of the Morley FEM in 30 lines of Matlab) with a scaling (which is generally understood and follows from the 

The first observation is that the \( F \) are the three point evaluations \( \delta \) with the real coefficients \( w \) for all \( z \) and \( \nu \) and \( M \in \mathcal{V} \) for all \( z \in \mathcal{V} \). Notice that the contributions of the piecewise quadratic \( v_2 \) and \( E \) reduces the analysis to piecewise quadratic functions. The first observation is that the left-hand side of (4.9) involves the polynomial \( v_2 - v_M \) in \( T \) for \( v_M := I_M v_pw \) that allows for

The second step reduces the analysis to piecewise quadratic functions. The first observation is that the averaging of the degrees of freedom in the definition of \( I_M \) merely employs the data of \( v_2 = I_M v_pw \) in the sense that \( v_M = I_M v_pw = I_M v_2 \). This explains why \( j_h (v_pw, T) = j_h (v_2, T) \) in the asserted estimate (4.9). The second observation is that the left-hand side of (4.9) involves the polynomial \( v_2 - v_M \) in \( T \) for \( v_M := I_M v_pw \) that allows for

The third step reduces the proof of (4.10) to six coefficients. The six degrees of freedom on a triangle \( T \in \mathcal{T} \) are the three point evaluations \( \delta_z \) at the three vertices \( z \in \mathcal{V}(T) \) and the three integral means of the normal derivatives \( \int_E \partial_{\nu_E} \cdot \, ds \) along the three edges \( E \in \mathcal{E}(T) \). The six dual basis functions \( \psi_z \) for \( z \in \mathcal{V}(T) \) and \( E \in \mathcal{E}(T) \) are defined by the duality relations \( \psi_E (z) = 0 = \int_E \partial_{\nu_E} \psi_z \, ds \) and \( \psi_z (z) = 1 = \int_E \partial_{\nu_E} \psi_E \, ds \) for all \( z \in \mathcal{V}(T) \) and \( E \in \mathcal{E}(T) \), while \( \psi_y (z) = 0 = \int_E \partial_{\nu_E} \psi_F \, ds \) for all vertices \( z \neq y \). This explains why the contributions of the piecewise quadratic \( v_2 \) are taken from \( T \) in \( \mathcal{T} \) and this is
written explicitly by \( v_2|_T \) in the coefficients, while the corresponding values of the Morley function \( v_M \in M(T) \) are independent of \( T \) as long as \( z \in \mathcal{V}(T) \) or \( E \in \mathcal{E}(T) \). Given the coefficients \( w(z) \) and \( w(E) \), the triangle inequality in \( L^2(T) \) and the scaling of the dual basis functions lead to

\[
\|v_2 - v_M\|_{L^2(T)} \lesssim h_T \sum_{z \in \mathcal{V}(T)} |w(z)| + h_T^2 \sum_{E \in \mathcal{E}(T)} |w(E)|.
\] (4.11)

The fourth step analyses the coefficients in (4.11). Let the triangles \( T(z) := \{ T \in T : z \in \mathcal{V}(T) \} = \{ T(1), \ldots, T(J) \} \) at the vertex \( z \in \mathcal{V} \) be enumerated such that \( T(j) \) and \( T(j + 1) \) share an edge \( \partial T(j) \cap \partial T(j + 1) =: E(j) \in \mathcal{E}(z) \) for \( j = 1, \ldots, J \). For an interior vertex \( z \in \mathcal{V}(\Omega) \), the patch is closed and then \( T(1) \) and \( T(J) \) share an edge \( \partial T(1) \cap \partial T(J) =: E(J) \in \mathcal{E}(z) \) as well. Define \( x_j := ((v_2 - v_M)|_{T(j)})\) for \( j = 1, \ldots, J \) and observe for an interior vertex \( z \in \mathcal{V}(\Omega) \) that \( \sum_{j=1}^{J} x_j = 0 \) (from the choice of \( v_M(z) \) as the arithmetic mean of the \( v_2|_{T(j)} \)) and that

\[
\sum_{E \in \mathcal{E}(z)} ||v_2|_E(z)|| = \sum_{j=1}^{J} |x_{j+1} - x_j|
\]

with \( x_{j+1} := x_1 \) (recall \( z \in \mathcal{V}(\Omega) \) here). Since the arithmetic mean of the real numbers \( x_1, \ldots, x_J \) vanishes, zero belongs to their convex hull; whence \( m := \min_{j=1, \ldots, J} x_j \leq 0 \leq \max_{j=1, \ldots, J} x_j =: \overline{m} \). A triangle inequality in this sequence \( x_1, \ldots, x_J \) shows that \( \overline{m} - m \leq \sum_{j=1}^{J} |x_{j+1} - x_j| \) (even with an omitted factor \( 1/2 \)). It follows \( |x_1|, \ldots, |x_J| \leq \sum_{j=1}^{J} |x_{j+1} - x_j| \) and so, for a triangle \( T \in \mathcal{T}(z) \) in the notation of (4.11),

\[
|w(z)| \leq \sum_{E \in \mathcal{E}(z)} ||v_2|_E(z)|| \leq J^{1/2} \sqrt{\sum_{E \in \mathcal{E}(z)} ||v_2|_E(z)||^2}
\] (4.12)

follows (with a Cauchy inequality in \( \mathbb{R}^J \) in the end). This is suboptimal and the best constant in a squared version of this argument is contained in Appendix C of [17]. Observe that \( J \lesssim 1 \) is bounded from above by the shape regularity of the triangulation \( \mathcal{T} \).

In the remaining case of a vertex \( z \in \mathcal{V}(\partial \Omega) \) on the boundary, \( v_M(z) = 0 \) and, in the above notation \( T(z) = \{ T \in T : z \in \mathcal{V}(T) \} = \{ T(1), \ldots, T(J) \} \) and \( x_j := ((v_2 - v_M)|_{T(j)})\) for \( j = 1, \ldots, J \). The homogeneous boundary conditions enter in the jump terms for \( E(1) := T_1 \cap \partial \Omega \) and \( E(J) := T_J \cap \partial \Omega \) and

\[
\sum_{E \in \mathcal{E}(z)} ||v_2|_E(z)|| = |x_1| + |x_J| + \sum_{j=1}^{J-1} |x_{j+1} - x_j|.
\]

Triangle inequalities show \( |x_1|, \ldots, |x_J| \leq |x_1| + |x_J| + \sum_{j=1}^{J-1} |x_{j+1} - x_j| \) (even with an omitted factor \( 1/2 \)) and the above arguments lead to (4.12) as well. (The optimal constant for this argument may be found in Lem. 4.2 of [11].)

Recall the design of the Morley interpolation in Definition 3.5 with the arithmetic mean \( \int_E \partial_{v_E} v_M \, ds = \int_E \left( \frac{\partial v_2}{\partial v_E} \right)_E \, ds \) of the two normal traces for an interior edge \( E = \partial T_+ \cap \partial T_- \in \mathcal{E}(\Omega) \). This leads to the edge contribution

\[
w(E) = \int_E \partial_{v_E} v_2|_T \, ds - \int_E \left( \frac{\partial v_2}{\partial v_E} \right)_E \, ds = \pm \frac{1}{2} \int_E [\partial_{v_E} v_2]|_E \, ds
\]

in (4.11) with a sign \( \pm \) for \( T = T_+ \). The boundary conditions for a boundary edge \( E \in \mathcal{E}(\partial \Omega) \) and the jump convention for \( [\bullet]|_E \) (recall that \( v_E \) points outwards for \( E \subset \partial \Omega \)) directly show \( w(E) = \int_E [\partial_{v_E} v_2]|_E \, ds \). It follows

\[
|w(E)| \leq \int_E [\partial_{v_E} v_2]|_E \, ds \quad \text{for any } E \in \mathcal{E}(T).
\] (4.13)
The fifth step finishes the proof. Recall that the coefficients \( w(z) \) for \( z \in \mathcal{V}(z) \) and \( w(E) \) for any \( E \in \mathcal{E}(T) \) in (4.11) satisfy (4.12) and (4.13). The resulting estimate reads

\[
h_T^4\|v_2 - v_M\|_{L^2(T)}^2 \lesssim h_T^2 \sum_{z \in \mathcal{V}(T)} \sum_{E \in \mathcal{E}(z)} \|v_2(z)\|^2 + \sum_{E \in \mathcal{E}(T)} \left| \int_E \left( \partial_{\nu_E} v_2 \right)_E \, ds \right|^2 \approx j_h (v_2, T)^2
\]

with the shape regularity \( h_T \approx h_T \) for \( F \in \mathcal{E}(z) \) and \( z \in \mathcal{V}(T) \) in the end. This concludes the proof of (4.10) and thus that of (a) as outlined at the end of the second step.

**Proof of (b).** Given any \( v_M \in M(T) \), part (a) shows that the first term \( T_1 \) in the equivalence (b) is \( T_1 \lesssim \|v_{pw} - w_M\|_{pw} + j_h (v_{pw} - w_M) \leq \|v_{pw} - w_M\|_h \) with \( j_h (v_{pw}) = j_h (v_{pw} - w_M) \) in the last step. Theorem 4.1 applies to \( v_{pw} - w_M \in H^2(T) \) and proves \( T_2 \lesssim \sum_{m=0}^2 |h_T^{-2} (v_{pw} - w_M)|_{H^m(T)} =: T_3. \) The estimates \( T_1 \lesssim T_2 \lesssim T_3 \) hold for all \( w_M \in M(T) \) and so for the respective minima as well. Since \( I_M v_{pw} \in M(T) \), the remaining estimate min \( w_M \in M(T) \) \( T_3 \) is obvious.

**Remark 4.4** \( (I_M J I_M = I_M \text{ in } H^2(T)) \). Let \( J \) be any right-inverse of \( I_M \) in the sense of (3.9). Since \( I_M J \) is identity in \( M(T) \), \( I_M J I_M v_{pw} = I_M v_{pw} \) holds for any \( v_{pw} \in H^2(T) \).

### 4.3. Approximation errors

The subsequent theorem discusses the approximation properties of \( J \circ I_M \) for piecewise smooth and piecewise quadratic functions. It is formulated in terms of \( \|v\|_h \approx \|v\|_{dG} \) and the norm equivalence implies an (undisplayed) analog for \( \|\cdot\|_{dG} \) as well.

**Theorem 4.5** (Approximation). Any \( v_{pw} \in H^2(T) \) and \( v_2 \in P_2(T) \) satisfy (a)–(d).

(a) \( \|v_{pw} - J I_M v_{pw}\|_h \approx \|1 - \Pi_0\| D_{pw}^2 \|v_{pw}\|_{L^2(\Omega)} + \min_{v \in H^2_0(\Omega)} \|v_{pw} - v\|_h \);  
(b) \( \sum_{m=0}^2 |h_T^{-2} (v_{pw} - J I_M v_{pw})|_{H^m(T)} \lesssim \|1 - \Pi_0\| D_{pw}^2 \|v_{pw}\|_{L^2(\Omega)} + \min_{v \in H^2_0(\Omega)} \sum_{m=0}^2 |h_T^{-2} (v_{pw} - v)|_{H^m(T)} \);  
(c) \( \|v_2 - J I_M v_2\|_h \approx \min_{v \in H^2_0(\Omega)} \|v_2 - v\|_h \approx \sum_{m=0}^2 |h_T^{-2} (v_2 - J I_M v_2)|_{H^m(T)} \approx \min_{v \in H^2_0(\Omega)} \sum_{m=0}^2 |h_T^{-2} (v_2 - v)|_{H^m(T)} \);  
(d) \( \|v_2 - J I_M v_2\|_{H^s(T)} \lesssim h_T^{-s} \min_{v \in H^2_0(\Omega)} \|v_2 - v\|_h \) holds for any \( 0 \leq s \leq 2 \).

**Remark 4.6**. Theorem 4.5 implies that \( P = Q = J \circ I_M \) is a quasi-optimal smoother with constant \( \Lambda_P = \Lambda_Q \) that depends only on the shape regularity of the triangulation.

**Remark 4.7** (Remainder in (a) and (b)). The extra term \( \|1 - \Pi_0\| D_{pw}^2 \|v_{pw}\|_{L^2(\Omega)} \) in the upper bound will vanish for piecewise quadratic functions but cannot be omitted in (a) and (b). For a proof of the latter statement by contradiction consider some \( v_{pw} \in H^2_0(\Omega) \setminus (HCT(T) + P_3(T)) \). Since \( J I_M v_{pw} \in HCT(T) + P_3(T) \), the left-hand side in (a) and (b) is positive, while \( v_{pw} \in H^2_0(\Omega) \) leads to a right-hand side zero if the term \( \|1 - \Pi_0\| D_{pw}^2 \|v_{pw}\|_{L^2(\Omega)} \) was neglected.

**Proof of (a).** Theorem 4.1 implies the first estimate (4.14a) below and Theorem 4.3a asserts the second (4.14b) for the Morley interpolation \( v_M := I_M v_{pw} \) of \( v_{pw} \in H^2(T) \) in

\[
\|v_{pw} - v_M\|_h \lesssim \sum_{m=0}^2 |h_T^{-2} (v_{pw} - v_M)|_{H^m(T)} \lesssim \|1 - \Pi_0\| D_{pw}^2 \|v_{pw}\|_{L^2(\Omega)} + j_h (v_{pw}).
\]

Notice that \( j_h (v_M - J v_M) = 0 \) implies \( \|v_M - J v_M\|_h = \|v_M - J v_M\|_{pw} \lesssim \|v_{pw} - v\|_{pw} \) for any \( v \in V \) from Lemma 3.7d in the last step. This and a triangle inequality, (4.14), and \( \|v_{pw} - v\|_{pw} + j_h (v_{pw}) \leq \sqrt{2} \|v_{pw} - v\|_h \) show

\[
\|v_M - J v_M\|_h \lesssim \|v_{pw} - v\|_{pw} + \|v_{pw} - v\|_{pw} \lesssim \|1 - \Pi_0\| D_{pw}^2 \|v_{pw}\|_{L^2(\Omega)} + \|v_{pw} - v\|_h.
\]

This and a triangle inequality \( \|v_{pw} - J I_M v_{pw}\|_h \lesssim \|v_{pw} - v_M\|_h + \|v_M - J v_M\|_h \) and (4.14), (4.15) conclude the proof of (a).\( \square \)
Proof of (b). Adapt the notation of part (a) and recall that Theorem 4.3a provides (4.14b), the second estimate in (4.14). Since \( v_M - Jv_M = I_M Jv_M - Jv_M \) (from (3.9)), Lemma 3.2 controls this interpolation error of \( Jv_M \in H^2_0(\Omega) \) and shows

\[
2 \sum_{m=0} |h_T^{-2} (v_M - Jv_M)|_{H_0^m(T)} \leq 2 \|v_M - Jv_M\|_{pw} \lesssim \| (1 - \Pi_0) D^2_{pw} v_{pw} \|_{L^2(\Omega)} + \|v_{pw} - v\|_h
\]

with (4.15) in the last step. Theorem 4.1 applies to \( v_{pw} - v \in H^2(T) \). The combination of the resulting estimate with the previous one concludes the proof of (b).

Proof of (c). The assertions (a) and (b) apply to \( v_{pw} := v_2 \in P_2(T) \) and the extra term \( \| (1 - \Pi_0) D^2_{pw} v_{pw} \|_{L^2(\Omega)} \) vanishes. The resulting estimates allow for obvious converse inequalities and so prove, for \( v_2 \in P_2(T) \) and \( v_M := I_M v_2 \in M(T) \), that

\[
\|v_2 - Jv_M\|_h \approx \min_{v \in H^2_0(\Omega)} \|v_2 - v\|_h \approx \sum_{m=0}^2 |h_T^{-2} (v_2 - Jv_M)|_{H_0^m(T)} \approx \min_{v \in H^2_0(\Omega)} \sum_{m=0}^2 |h_T^{-2} (v_2 - v)|_{H_0^m(T)}
\]

with Theorem 4.1 in between the two equivalences. A triangle inequality, the estimate (4.14b), the estimate for \( h_T^{-2} (v_2 - Jv_M) \) in the proof of (b) and (4.1) applies to \( v_{pw} := v_2 \in P_2(T) \) shows \( \|v_2 - v\|_h \approx J_h (v_2 - v) + \|v_2 - v\|_h \leq 2 \|v_2 - v\|_h \) for any \( v \in H^2_0(\Omega) \). This concludes the proof of (c).

Proof of (d). The equivalence of the Sobolev–Slobodeckii norm and the norm by interpolation of Sobolev spaces ([35], Rem. 9.1), for instance for a fixed reference triangle \( T = T_{ref} \) with \( C_2(s) = C_2(s, T_{ref}) \), provides for \( w := (v_2 - JI_M v_2)|_T \in H^2(T) \) the estimate

\[
\|w\|_{H^s(T)} \leq C_2(s) \|w\|_{H^{2-s}(T)} \|w\|_{H^{2s-1}(T)} \quad \text{for} \ 1 < s < 2. \tag{4.16}
\]

A straightforward transformation of Sobolev norms ([26], Thm. 3.1.2) show (4.16) for any triangle \( T \in T \) with \( C_2(s) = C_2(s, T) = \kappa_1^{1-s} C_2(s, T_{ref}) \) for the condition number \( \kappa = \sigma_1 / \sigma_2 \) of the affine transformation \( a + Bx \) of \( T_{ref} \) to \( T \) with the 2 x 2 matrix \( B \) and its positive singular values \( \sigma_2 \leq \sigma_1 \). A more detailed analysis [15] reveals that \( C_2(s) \) exclusively depends on \( s \) (but exploits singularities as \( s \) approaches the end-points 0 and 1). The estimate (4.16) shows the first inequality in

\[
C_2(s)^2 \|w\|_{H^s(T)}^2 \lesssim \|w\|_{H^{2-s}(T)}^2 \|w\|_{H^{2s-1}(T)}^2 \lesssim \|w\|_{H^s(T)}^2 + \|w\|_{H^{2-s}(T)}^2 \|w\|_{H^{2s-1}(T)}^2
\]

with the subadditivity \( (a + b)^p \leq a^p + b^p \) for \( a, b \geq 0 \) and \( 0 < p = s - 1 < 1 \) (e.g., from the concavity of \( x \mapsto x^p \) for non-negative \( x \)) in the last step. An elementary estimate is followed by the Young inequality \( ab \leq a^p / p + b^q / q \) for \( p = (2 - s)^{-1} \), \( q = (s - 1)^{-1} \), \( a = \|h_T^{-1} w\|_{H^{2-s}(T)}^2 \) and \( b = \|w\|_{H^{s-1}(T)}^2 \) to prove

\[
\max_{h_T^{-2}} \|w\|_{H^s(T)}^2 \|w\|_{H^{2-s}(T)}^2 \lesssim \\lesssim \|h_T^{-1} w\|_{H^{2-s}(T)}^2 \|w\|_{H^{s-1}(T)}^2 \lesssim \|h_T^{-1} w\|_{H^{2-s}(T)}^2 + \|w\|_{H^{s-1}(T)}^2.
\]

This and the trivial estimate \( h_{max}^{2(s-1)} \leq \text{diam}(\Omega)^{2(s-1)} \) leads to

\[
\|w\|_{H^s(T)}^2 \leq C_3 \|w\|_{H^{2-s}(T)}^2 \|w\|_{H^{s-1}(T)}^2 \lesssim \|w\|_{H^{2-s}(T)}^2 \|w\|_{H^{s-1}(T)}^2
\]

for \( C_3 = C_2(s)^2 (1 + \text{diam}(\Omega)^{2(s-1)}) \). The sum over all those contributions over \( T \in T \) proves

\[
\|v_2 - JI_M v_2\|_{H^s(T)} \leq C_3 \|h_T^{-2} (v_2 - JI_M v_2)|_{H^{2-s}(T)} + \|v_2 - JI_M v_2\|_{pw}
\]
with Theorem 4.5c in the last step. This concludes the proof of (d) for $1 < s < 2$. The assertion (d) is included in Theorem 4.5c for $s = 0, 1, 2$. The remaining case $0 < s < 1$ is similar to the above analysis with $\|w\|_{H^s(T)} \leq C_2(s)\|w\|_{L^2(T)}\|w\|_{H^s(T)}$ replacing (4.16) and analogous arguments; hence further details are omitted. \hfill \qed

5. ABSTRACT FRAMEWORK FOR BEST-APPROXIMATION OF LOWER-ORDER METHODS

5.1. Discretisation

Suppose that $V_h \subset H^2(T)$ is the finite-dimensional trial and test space of an abstract (discontinuous Galerkin) scheme with a bilinear form $A_h : (V_h + M(T)) \times (V_h + M(T)) \rightarrow \mathbb{R}$ that is coercive and continuous with respect to some norm $\| \bullet \|_h$ in $H^2(T)$ in the sense that, for all $v_h, w_h \in V_h,$

$$\alpha \|v_h\|^2_h \leq A_h(v_h, v_h) \quad \text{and} \quad A_h(v_h, w_h) \leq M \|v_h\|_h \|w_h\|_h \quad (5.1)$$

hold for some universal constants $0 < \alpha, M < \infty.$ Suppose that $\| \bullet \|_h$ is a norm in $H^2(T)$ and equal to the norm $\| \bullet \|_{pw} := a_{pw}(\bullet, \bullet)^{1/2}$ in $V + M(T)$ and stronger in general, i.e.,

(a) $\| \bullet \|_{pw} \leq \| \bullet \|_h$ in $H^2(T)$ \quad and \quad (b) $\| \bullet \|_{pw} = \| \bullet \|_h$ in $V + M(T). \quad (5.2)$

Given a linear operator $JI_M : V_h \rightarrow V$ with the companion operator $J$ from Lemma 3.7 and the (extended) linear interpolation operator $I_M$ from Section 3.3 the discrete problem reads: Given $F \in V^* = H^{-2}(\Omega)$ seek the discrete solution $u_h \in V_h$ to

$$A_h(u_h, v_h) = F(JI_M v_h) \quad \text{for all} \quad v_h \in V_h. \quad (5.3)$$

The Lax-Milgram lemma assures the existence of a unique discrete solution $u_h$ to (5.3).

Remark 5.1 ($\| \bullet \|_h$). The examples of Sections 7 and 8 utilize $\| \bullet \|_h$ given in (4.1) and (4.2), but the abstract framework allows more general $A_h$ and $\| \bullet \|_h$ with (5.1) and (5.2) in (5.3).

5.2. First glance at the analysis

This subsection motivates the abstract conditions and emphasises the relevance of the discrete consistency condition (dcc)

$$a_{pw}(I_M u, e_h - I_M e_h) + b_h(I_M u, e_h - I_M e_h) \leq \Lambda_{dc} \|u - I_M u\|_{pw} \|e_h\|_h \quad (5.4)$$

that leads to the best-approximation in terms of $\|u - I_M u\|_{pw} = \min_{v_2 \in P_2(T)} \|u - v_2\|_{pw}$ from (3.7). The test function $e_h := I_h I_M u - u_h \in V_h \subset H^2(T)$ is the discrete approximation of the error $u - u_h$ with $I_M : H^2(T) \rightarrow M(T)$ from Definition 3.5 and a transfer operator $I_h : M(T) \rightarrow V_h$ from Section 5.3 below. For the dGFEM of Section 7 and the WOPSIP scheme of Section 10, $I_h$ is the identity 1 and otherwise it is controlled nicely (cf., (5.11) below for details) [23]. So we may neglect the difference $1 - I_h$ for the sake of this first look at the analysis and suppose $I_h = 1$. The key identity from the continuous problem (3.1) and the discrete one (5.3) reads

$$a(u, JI_M e_h) = F(JI_M e_h) = A_h(u_h, e_h). \quad (5.5)$$

The stability of the scheme $\alpha \|e_h\|^2_h \leq A_h(e_h, e_h) \leq M \|e_h\|^2_h$ motivates the investigation of

$$A_h(e_h, e_h) = a_{pw}(e_h, e_h) + b_h(e_h, e_h) + c_h(e_h, e_h) \quad (5.6)$$
for the three bilinear forms that define the class of problems in (5.12) displayed in Table 1. The stability term \( c_h(\cdot, \cdot) \) is controlled nicely in harmony with the discrete norm \( \| \cdot \|_h \), while \( b_h(\cdot, \cdot) \) drives the method and completes the leading term \( a_{pw}(\cdot, \cdot) \).

The definition of \( e_h \) in (5.6) leads to

\[
A_h(e_h, e_h) = a_{pw}(I_M u, e_h) - A_h(u_h, e_h) + b_h(I_M u, e_h) + c_h(I_M u, e_h) \tag{5.7}
\]

Since \( J \) is a the right-inverse of \( I_M \), (3.5) implies \( a_{pw}(I_M u, I_M e_h - J I_M e_h) = 0 \). This and elementary algebra show

\[
a_{pw}(I_M u, e_h) = a_{pw}(I_M u, e_h - I_M e_h) + a_{pw}(I_M u, J I_M e_h).
\]

This in combination with (5.5) leads to

\[
A_h(e_h, e_h) = a_{pw}(I_M u, e_h - I_M e_h) + a_{pw}(I_M u - u, J I_M e_h) + b_h(I_M u, e_h) + c_h(I_M u, e_h). \tag{5.8}
\]

The second term in the right-hand side of (5.8) is equal to \( a_{pw}(I_M u - u, J I_M e_h - I_M e_h) \) and the stabilisation term is equal to \( c_h(I_M u - u, e_h) \). They are controlled by \( \| u - I_M u \|_{pw} \| e_h \|_h \). The bilinear form \( b_h \) enjoys the miraculous property \( b_h(I_M u, I_M e_h) = 0 \) for the discontinuous Galerkin schemes of this paper. The remaining term on the right-hand side of (5.8) is \( a_{pw}(I_M u, e_h - I_M e_h) + b_h(I_M u, e_h - I_M e_h) \) and in fact controlled by the dcc (5.4). The proof of dcc in Section 8 is one key argument in this paper.

**Remark 5.2.** The arguments in this section applies to the case where \( A_h(\cdot, \cdot) \) satisfies an inf-sup condition; (and not the coercivity condition). The key idea is to estimate the consistency error \( F(J I_M v_h) - A_h(I_M u, v_h) \) using (5.5) and (5.6) and the orthogonality of the interpolation operator.

### 5.3. Transfer operators between \( V_h \) and \( M(T) \)

Recall \( I_M : H^2(T) \to M(T) \) from Definition 3.5, and suppose the existence of some constant \( \Lambda_M \geq 0 \) with

\[
\| v_h - I_M v_h \|_h \leq \Lambda_M \| v_h - v \|_h \quad \text{for all } v_h \in V_h \text{ and all } v \in V. \tag{5.9}
\]

Suppose the existence of constants \( \Lambda'_M, M_M \geq 0 \), and boundedness in the sense that

\[
\begin{align*}
\| v_h - I_M v_h \|_h &\leq \Lambda'_M \| v_h \|_h \quad \text{for all } v_h \in V_h, \\
\| I_M v_h \|_{pw} &\leq M_M \| v_h \|_h \quad \text{for all } v_h \in V_h. \tag{5.10}
\end{align*}
\]

Apparently \( \Lambda'_M \leq \Lambda_M \) (with \( v = 0 \)) and \( M_M \leq 1 + \Lambda'_M \) (with (5.2a) and a triangle inequality). The possibly smaller constant \( M_M \) enters in Theorem 5.4a, while \( \Lambda_M \) appears in Theorems 5.4b and 6.2 below. The above conditions control the transfer from \( V_h \) into \( M(T) \) via \( I_M : V + V_h + M(T) \to M(T) \).

The transfer from \( M(T) \) into \( V_h \) is modeled by some linear map \( I_h : M(T) \to V_h \) that is bounded in the sense that there exists some constant \( \Lambda_h > 0 \) such that

\[
\| v_M - I_h v_M \|_h \leq \Lambda_h \| v_M - v \|_{pw} \quad \text{for all } v_M \in M(T) \text{ and for all } v \in V. \tag{5.11}
\]

The examples of this paper concern the discrete norm from (4.1), (4.2) and then the estimates of this subsection follow for piecewise quadratic discrete spaces.

**Example 5.3** (Equations (5.9) and (5.10) hold for \( V_h \subseteq P_2(T) \) and (4.1), (4.2)). Suppose that the discrete norm \( \| \cdot \|_h \) is defined by (4.1), (4.2) and \( V_h \subseteq P_2(T) \). Then (5.2) and (5.9), (5.10) follow.
Proof of (5.9) and (5.10). Given any \( v_2 \in P_2(T) \) and any \( v \in V \), a triangle inequality shows
\[
\|v_2 - I_Mv_2\|_h \leq \|v_2 - JI_Mv_2\|_h + \|I_Mv_2 - JI_Mv_2\|_h =: t_1 + t_2.
\]
Theorem 4.5c controls the first term \( t_1 := \|v_2 - JI_Mv_2\|_h \lesssim \|v_2 - v\|_h \) on the right-hand side. Since \( j_h(v_M) = 0 \) in (4.2) vanishes for \( v_M := I_Mv_2 \in M(T) \), the second term \( t_2 := \|v_M - Jv_M\|_{pw} \lesssim \|v_M - v\|_{pw} \) with Lemma 3.7d in the last step. Since \( \|(1 - \Pi_0)D^2_{pw}v_2\| = 0 \) vanishes for \( v_2 \in P_2(T) \), Theorem 4.3a shows \( \|v_M - v_2\|_{pw} \lesssim j_h(v_2) = j_h(v_2 - v) \leq \|v_2 - v\|_h \) with (4.1) and (4.2) in the last two steps. This and a triangle inequality prove \( t_2 \lesssim \|v_2 - v\|_h \). The combination of the estimates for \( t_1 + t_2 \lesssim \|v_2 - v\|_h \) proves (5.9); and (5.9) immediately implies (5.10) as discussed above. \( \square \)

5.4. Sufficient conditions for best-approximation

The key assumption in abstract form is the discrete consistency condition
\[
\text{Discrete consistency condition:}
\]
This is a straightforward generalization of (5.4) from Sect. 5.2. Assume that the bilinear form
\[
\mathcal{A}_h(\hat{v}, \hat{w}) := a_{pw}(\hat{v}, \hat{w}) + b_h(\hat{v}, \hat{w}) + c_h(\hat{v}, \hat{w}) \quad \text{for all } \hat{v}, \hat{w} \in V_h + M(T).
\]
The key assumption in abstract form is the discrete consistency condition with a constant \( 0 < \Lambda_{dc} < \infty \): All functions \( v_M \in M(T) \), \( w_h \in V_h \), and all \( v, w \in V \) satisfy
\[
a_{pw}(v_M, w_h - I_Mw_h) + b_h(v_M, w_h - I_Mw_h) \leq \Lambda_{dc}\|v_M - v\|_{pw}\|w_h - w\|_h.
\]
(3.1)

\[
(3.1)
\]

This is a straightforward generalization of (5.4) from Sect. 5.2.) Assume that \( b_h : (V_h + M(T)) \times (V_h + M(T)) \to \mathbb{R} \) is bounded in \( V_h + M(T) \) by a constant \( 0 < M_b < \infty \) and vanishes in \( M(T) \times M(T) \) in the sense that all \( v_h, w_h \in V_h \) and all \( v_M, w_M \in M(T) \) satisfy
\[
b_h(v_M, w_M) = 0,
\]
(3.14)

\[
b_h(v_h + v_M, w_h + w_M) \leq M_b\|v_h + v_M\|_h\|w_h + w_M\|_h.
\]
(3.15)

Suppose that the bilinear form \( c_h : (V_h + M(T)) \times (V_h + M(T)) \to \mathbb{R} \) and a constant \( 0 < \Lambda_c < \infty \) satisfy
\[
c_h(v_h, w_h) \leq \Lambda_c\|v - v_h\|_h\|w - w_h\|_h \quad \text{for all } v_h, w_h \in V_h \text{ and } v, w \in V.
\]
(3.16)

Theorem 5.4 (Best-approximation). Suppose (5.1), (5.2) and (5.9)–(5.16). Let \( u \in V \) solve (3.1) and let \( u_h \in V_h \) solve (5.3). Then
\[
(a) \quad \|u - u_h\|_h \leq C_{q_0}\|u - I_Mu\|_{pw} \quad \text{and} \quad (b) \quad \|u - JI_Mu_h\| \leq (1 + \Lambda_M)(1 + \Lambda_j)\|u - u_h\|_h
\]
hold with the constant \( C_{q_0} := 1 + \Lambda_h + \alpha^{-1}(\Lambda_0 M_M + \Lambda_h (1 + M_b) + \Lambda_{dc} + \Lambda_c (1 + \Lambda_h)) \).

Remark 5.5. The Morley FEM is included in the (non-symmetric) abstract framework of Theorem 5.4 and leads to a sub-optimal best-approximation constant \( C_{q_0} = 1 + \Lambda_h \).

The error analysis of a post-processing dates back at least to [6] with a design of an enrichment operator for C\(^0\)IP functions replaced here by the smoother \( JI_M \). For \( F \in H^{-\sigma}(\Omega) \) with \( 2 - \sigma \leq s \leq 2 \) (and \( u \in H^{1+s}(\Omega) \) from elliptic regularity), Theorem 5.4 verifies
\[
\|u - JI_Mu_h\| \leq C_{q_0}(1 + \Lambda_M)(1 + \Lambda_j)\|u - I_Mu\|_{pw} \lesssim h^{2-s}\max\|F\|_{H^{-\sigma}(\Omega)}.
\]
5.5. Proofs

Abbreviate \( e_h := I_h I_M u - u_h \in V_h \) and \((a_{pw} + b_h)(\bullet, \bullet) := a_{pw}(\bullet, \bullet) + b_h(\bullet, \bullet)\) for the sum of the bilinear forms.

**Lemma 5.6** (Key identity). It holds

\[
A_h(e_h, e_h) = a_{pw}(u, (1 - J)I_M e_h) + (a_{pw} + b_h)((I_h - 1)I_M u, e_h) + (a_{pw} + b_h)(I_M u, e_h) + e_h(I_h I_M u, e_h).
\]

**Proof.** The test function \( v := JI_M e_h \in V \) in (3.1) and the test function \( v_h := e_h \in V_h \) in (5.3) lead to

\[
a(u, JI_M e_h) = F(JI_M e_h) = A_h(u_h, e_h).
\]

This and the definition \( e_h = I_h I_M u - u_h \) result in

\[
A_h(e_h, e_h) = A_h(I_h I_M u, e_h) - a(u, JI_M e_h).
\]

The identity \( a_{pw}(u, I_M e_h) = a_{pw}(I_M u, I_M e_h) \) from (3.5) shows that this is equal to

\[
a_{pw}(u, (1 - J)I_M e_h) + A_h(I_h I_M u, e_h) - a_{pw}(I_M u, I_M e_h).
\]

The last term \( a_{pw}(I_M u, I_M e_h) \) is part of \( A_h(I_M u, I_M e_h) \) by (5.12), while \( b_h(I_M u, I_M e_h) = 0 \) owing to (5.14). This and elementary algebra conclude the proof.

**Lemma 5.7.** The assumptions (3.5), (3.9), (3.11), and (5.10) imply

\[
a_{pw}(u, (1 - J)I_M e_h) \leq \Lambda_0 M_M \| u - I_M u \|_{pw} \| e_h \|_h.
\]

**Proof.** Set \( v_M := I_M e_h \) and recall \( I_M(v_M - Jv_M) = 0 \) from (3.9). The orthogonality (3.5) and the Cauchy inequality with respect to \( a_{pw}(\bullet, \bullet) \) imply

\[
a_{pw}(u, (1 - J)v_M) = a_{pw}(u - I_M u, (1 - J)v_M) \leq \| u - I_M u \|_{pw} \| (1 - J)v_M \|_{pw}.
\]

The boundedness of \( 1 - J \) in (3.11) and the boundedness of \( I_M \) in (5.10) show

\[
\| (1 - J)v_M \|_{pw} \leq \Lambda_0 \| v_M \|_{pw} \leq \Lambda_0 M_M \| e_h \|_h.
\]

The combination of the two displayed inequalities concludes the proof.

**Lemma 5.8.** The assumptions (5.2), (5.11), and (5.15) imply

\[
(a_{pw} + b_h)((I_h - 1)I_M u, e_h) \leq \Lambda_h (1 + M_h) \| u - I_M u \|_{pw} \| e_h \|_h.
\]

**Proof.** For \( e_h \in V_h \) and \( I_M u \in M(\mathcal{T}) \), the Cauchy inequality plus (5.2a) show

\[
a_{pw}((I_h - 1)I_M u, e_h) \leq \| (1 - I_h)I_M u \|_h \| e_h \|_h.
\]

This and the boundedness of \( b_h \) in (5.15) result in

\[
(a_{pw} + b_h)((I_h - 1)I_M u, e_h) \leq (1 + M_h) \| (1 - I_h)I_M u \|_h \| e_h \|_h.
\]

The inequality (5.11) with \( v_M = I_M u \) and \( v = u \) reads

\[
\| (1 - I_h)I_M u \|_h \leq \Lambda_h \| u - I_M u \|_{pw}.
\]

The combination of the last two displayed inequalities concludes the proof.
Lemma 5.9. The assumptions (5.2), (5.11), (5.13), and (5.16) imply
\[(a_{pw} + b_h)(I_M u, e_h - I_M e_h) + c_h(I_h I_M u, e_h) \leq (\Lambda_{dc} + \Lambda_c(1 + \Lambda_h))\|u - I_M u\|_{pw}\|e_h\|_h.\]

Proof. The discrete consistency condition (5.13) for \(v_M := I_M u, w_h := e_h, v := u,\) and \(w := 0\) lead to the upper bound
\[(a_{pw} + b_h)(I_M u, e_h - I_M e_h) \leq \Lambda_{dc}\|u - I_M u\|_{pw}\|e_h\|_h\]
for the first term on the left-hand side of the asserted estimate. The remaining contribution \(c_h(I_h I_M u, e_h)\) is controlled in (5.16) with \(v_h := I_h I_M u, w_h := e_h, v = u,\) and \(w = 0\) by
\[c_h(I_h I_M u, e_h) \leq \Lambda_c\|u - I_h I_M u\|_h\|e_h\|_h.\]

A triangle inequality in \(\|\bullet\|_h,\) (5.11) with \(v_M := I_M u\) and \(v = u,\) and (5.2b) show
\[\|u - I_h I_M u\|_h \leq (1 + \Lambda_h)\|u - I_M u\|_{pw}.\]

The combination of the resulting inequalities concludes the proof. \(\Box\)

Proof of best-approximation in Theorem 5.4a. The discrete ellipticity (5.1) is followed by Lemma 5.6 with terms controlled in Lemmas 5.7–5.9. This leads (after a division by \(\|e_h\|_h,\) if positive) to
\[\alpha\|e_h\|_h \leq (\Lambda_0 M + \Lambda_h(1 + M_h) + \Lambda_{dc} + \Lambda_c(1 + \Lambda_h))\|u - I_M u\|_{pw}.\]

On the other hand, \(\|(I_h - 1)I_M u\|_h \leq \Lambda_h\|u - I_M u\|_{pw}\) from (5.11) for \(v_M := I_M u\) and \(v := u.\) Triangle inequalities in \(\|\bullet\|_h,\) (5.2b), and the last two inequalities result in
\[\|u - u_h\|_h \leq \|u - I_M u\|_{pw} + \|I_M u - I_h I_M u\|_h + \|e_h\|_h \leq C_{qo}\|u - I_M u\|_{pw}\]
with the constant \(C_{qo},\) displayed in the assertion. \(\Box\)

Proof for post-processing in Theorem 5.4b. The assertion (b) is formulated in terms of \(u\) and \(u_h\) but holds for general \(v_h \in V_h\) and \(v \in V\) and the abbreviation \(v_M := I_M v_h \in M(\mathcal{T}).\) A triangle inequality and Lemma 3.7d prove
\[\|v - J v_M\| \leq \|v - v_M\|_{pw} + \|(1 - J)v_M\|_{pw} \leq (1 + \Lambda_J)\|v - v_M\|_{pw}.\]

A triangle inequality, (5.2a) twice, and (5.9) show
\[\|v - v_M\|_{pw} \leq \|v - v_h\|_{pw} + \|v_h - v_M\|_h \leq (1 + \Lambda_M)\|v - v_h\|_h.\]

The combination of the two displayed estimates reads
\[\|v - J v_M\| \leq (1 + \Lambda_J)(1 + \Lambda_M)\|v - v_h\|_h.\] \(\Box\)

6. WEAKER AND PIECEWISE SOBOLEV NORM ERROR ESTIMATES

6.1. Assumptions and result

This subsection presents one further condition sufficient for a lower-order \textit{a priori} error estimate for the discrete problem (5.3) beyond the hypotheses of Sections 5.1–5.4: The \textit{dual discrete consistency} with a constant \(0 \leq \Lambda_{ddc} < \infty\) asserts that any \(v_M \in V_h, w_M \in M(\mathcal{T}),\) and any \(v, w \in V\) satisfy
\[a_{pw}(v_h - I_M v, w_M) + b_h(v_h, w_M) \leq \Lambda_{ddc}\|v - v_h\|_h\|w - w_M\|_{pw}. \tag{6.1}\]
6.2. Duality and algebra

Then there exist constants $C_4(s), C_5(s) > 0$ such that (a) and (b) hold for any $F \in H^{-s}(\Omega)$ with solution $u \in V$ to (3.1) and the solution $u_h \in V_h$ to (5.3). (a) $\|u - JI_M u_h\|_{H^\ast(\Omega)} \leq C_4(s) h^{2-s} \|u - u_h\|_h$ and (b), if $u_h \in P_2(T)$, then $\|u - u_h\|_{H^\ast(T)} \leq C_5(s) h^{2-s} \|u - u_h\|_h$.

6.2. Duality and algebra

The duality of $H^{-s}(\Omega)$ and $H^s_0(\Omega)$ reveals for the exact solution $u \in V$ to (3.1) and the post-processing $v := JI_M u_h \in V$ of the discrete solution $u_h \in V_h$ to (5.3) that

$$\|u - v\|_{H^\ast(\Omega)} = \sup_{0 \neq G \in H^{-s}(\Omega)} \frac{G(u - v)}{\|G\|_{H^{-s}(\Omega)}} = G(u - v).$$

The supremum is attained for some $G \in H^{-s}(\Omega) \subset V^\ast$ with norm $\|G\|_{H^{-s}(\Omega)} = 1$ owing to a corollary of the Hahn–Banach theorem. The functional $a(z, \bullet) = G \in V^\ast$ has a unique Riesz representation $z \in V$ in the Hilbert space $(V, a)$; $z \in V$ is the weak solution to the PDE $\Delta^2 z = G$. The elliptic regularity (as in Example 3.1) leads to $z \in V \cap H^{4-s}(\Omega)$ with $2 \leq 4 - s \leq 2 + \sigma$ and (3.2); hence

$$\|u - v\|_{H^\ast(\Omega)} = a(u - v, z) \quad \text{and} \quad \|z\|_{H^{4-s}(\Omega)} \leq C_{\text{reg}}.$$ 

The proof of Theorem 6.2 consists of a series of lemmas to establish an upper bound of $a(u - v, z)$ for the above $z \in V \cap H^{4-s}(\Omega)$. The notation

$$v := JI_M u_h \in V, \quad z_h := I_M z \in V_h \quad \text{and} \quad \zeta := JI_M z_h \in V$$

for the discrete, exact, and dual solution $u_h, u$, and $z$ applies throughout this section.

Lemma 6.3 (Key identity). It holds

$$a(u - v, z) = a(u - v, z - \zeta) + a_{\text{pw}}(u_h - v, \zeta - z_h) + a_{\text{pw}}(I_M u_h - v, z_h - I_M z_h)$$

$$+ a_{\text{pw}}(u_h - I_M u_h, I_M z_h - \zeta) + A_h(u_h, z_h) - a_{\text{pw}}(u_h, I_M z_h) + a_{\text{pw}}(u_h - I_M u_h, z_h).$$

Proof. Let $\zeta \equiv JI_M z_h \in V$ substitute the test function $v$ in (3.1). This and the test function $v_h := z_h$ in (5.3) lead to

$$a(u, \zeta) = F(\zeta) = A_h(u_h, z_h).$$

This identity and elementary algebra result in

$$a(u - v, \zeta) = a_{\text{pw}}(u_h - v, \zeta - z_h) + a_{\text{pw}}(I_M u_h - v, z_h) + a_{\text{pw}}(u_h, (1 - J) I_M z_h)$$

$$+ A_h(u_h, z_h) - a_{\text{pw}}(u_h, I_M z_h) + a_{\text{pw}}(u_h - I_M u_h, z_h).$$

The formulas $a_{\text{pw}}((1 - J) I_M u_h, I_M z_h) = 0 = a_{\text{pw}}(I_M u_h, (1 - J) I_M z_h)$ (from (3.5) and (3.9)) and elementary algebra conclude the proof. □
6.3. Elementary bounds

Lemma 6.4. Each of the following terms (a) $a(u-v, z-\zeta)$, (b) $a_{pw}(u_h-v, \zeta-z_h)$, (c) $a_{pw}(I_Mu_h-v, z_h-I_Mz_h)$, and (d) $a_{pw}(u_h-I_Mu_h, I_Mz_h-\zeta)$ is bounded in modulus by a constant $\leq (1 + (1 + \Lambda_J)(1 + \Lambda_M))^2(1 + \Lambda_h)$ times $\|u - u_h\|_h \|z - I_M z\|_{pw}$.

Proof. The assumption (5.9) (with $(v, v_h)$ replaced by $(u, u_h)$ and $(z, z_h)$) implies

$$\|u_h - I_Mu_h\|_h \leq \Lambda_M \|u - u_h\|_h \quad \text{and} \quad \|z_h - I_Mz_h\|_h \leq \Lambda_M \|z - z_h\|_h. \tag{6.2}$$

Recall $v \equiv JI_Mu_h$ and $\zeta \equiv JI_Mz_h \in V$ to deduce from Lemma 3.7d that

$$\|v - I_Mu_h\|_{pw} \leq \Lambda_J \|u - I_Mu_h\|_{pw} \quad \text{and} \quad \|\zeta - I_Mz_h\|_{pw} \leq \Lambda_J \|z - I_Mz_h\|_{pw}. \tag{6.3}$$

The combination of (6.2)-(6.3) with (5.2a) and triangle inequalities lead to

$$\|u - v\| \leq \|u - I_Mu_h\|_{pw} + \|v - I_Mu_h\|_{pw} \leq (1 + \Lambda_J)\|u - I_Mu_h\|_{pw} \leq (1 + \Lambda_J)(\|u - u_h\|_{pw} + \|u_h - I_Mu_h\|_h) \leq (1 + \Lambda_J)^2(1 + \Lambda_M)\|u - u_h\|_h. \tag{6.4}$$

The above arguments have not utilized any solution property and hence also apply for $(z, \zeta, z_h)$ replacing $(u, v, u_h)$ to reveal (instead of (6.4))

$$\|z - \zeta\| \leq (1 + \Lambda_J)(1 + \Lambda_M)\|z - z_h\|_h. \tag{6.5}$$

Consider $v_M := I_Mz \in M(T)$ with $z_h \equiv I_h I_Mz = I_h v_M$ in (5.11) to show

$$\|z_h - I_Mz\|_h \leq \Lambda_h \|z - I_Mz\|_{pw}. \tag{6.6}$$

This, a triangle inequality, and (5.2b) result in

$$\|z - z_h\|_h \leq (1 + \Lambda_h)\|z - I_Mz\|_{pw}. \tag{6.7}$$

The combination of (6.5) and (6.7) proves

$$\|z - \zeta\| \leq (1 + \Lambda_J)(1 + \Lambda_M)(1 + \Lambda_h)\|z - I_Mz\|_{pw}. \tag{6.8}$$

Proof of (a). This follows from a Cauchy inequality plus (6.4) and (6.8). \hfill \Box

Proof of (b). A triangle inequality, (5.2a), and (6.4) verify

$$\|u_h - v\|_{pw} \leq \|u_h - v\|_h \leq (1 + (1 + \Lambda_J)(1 + \Lambda_M))\|u - u_h\|_h. \tag{6.9}$$

The triangle inequality with (5.2a) and (6.7)-(6.8) show

$$\|\zeta - z_h\|_{pw} \leq \|\zeta - z_h\|_h \leq (1 + \Lambda_h)(1 + (1 + \Lambda_J)(1 + \Lambda_M))\|z - I_Mz\|_{pw}. \tag{6.10}$$

A Cauchy inequality and the preceding estimates conclude the proof of (b). \hfill \Box

Proof of (c). The estimate (6.3), a triangle inequality, (5.2a), and (6.2) show

$$\|v - I_Mu_h\|_{pw} \leq \Lambda_J \|u - I_Mu_h\|_{pw} \leq \Lambda_J(1 + \Lambda_M)\|u - u_h\|_h. \tag{6.9}$$

The combination of (6.2) and (6.7) after (5.2a) leads to

$$\|z_h - I_Mz_h\|_{pw} \leq \|z_h - I_Mz_h\|_h \leq \Lambda_M(1 + \Lambda_h)\|z - I_Mz\|_{pw}. \tag{6.10}$$

A Cauchy inequality and the preceding estimates conclude the proof of (c). \hfill \Box

Proof of (d). This follows from a Cauchy inequality with (5.2a) and the estimates for $\|u_h - I_Mu_h\|_h$ in (6.2) and $\|\zeta - I_Mz_h\|_{pw}$ in (6.3). \hfill \Box
6.4. Discrete consistency bounds

Lemma 6.5. It holds

\[
A_h(u_h, z_h) - a_{pw}(u_h, I_M z_h) + a_{pw}(u_h - I_M u_h, z_h) \\
\leq (1 + \Lambda_h)((2 + M_b)A_M^2 + (\Lambda_{dc} + \Lambda_{ddc})(1 + \Lambda_M)A_J + \Lambda_c)\|u - u_h\|_h \|z - I_M z\|_{pw}.
\]

Proof. Recall \(b_h(I_M u_h, I_M z_h) = 0\) from (5.14) and exploit (5.12) with elementary (but lengthy) algebra to check that the left-hand side LHS of the assertion is equal to

\[
\text{LHS} = (2a_{pw} + b_h)(u_h - I_M u_h, z_h - I_M z_h) + (a_{pw} + b_h)(I_M u_h, z_h - I_M z_h) + (a_{pw}(u_h - I_M u_h, I_M z_h) + b_h(u_h, I_M z_h)) + c_h(u_h, z_h) \tag{6.11}
\]

with the short notation, e.g., \((2a_{pw} + b_h)(\bullet, \bullet) = 2a_{pw}(\bullet, \bullet) + b_h(\bullet, \bullet)\), for the sum of the bilinear forms announced in Section 5.5. The two lines (6.11) and (6.12) of expressions for the LHS give rise to four estimates. The continuity of \(a_{pw}(\bullet, \bullet)\) and \(b_h(\bullet, \bullet)\) in (5.15), (6.2), and (6.10) prove

\[
(2a_{pw} + b_h)(u_h - I_M u_h, z_h - I_M z_h) \leq (2 + M_b)A_M^2(1 + \Lambda_h)\|u - u_h\|_h \|z - I_M z\|_{pw}.
\]

The discrete consistency (5.13) leads in the last term in (6.11) to a product of \(\|v - I_M u_h\|_{pw}\) controlled in (6.9) and \(\|z - z_h\|_h\) controlled in (6.7). This results in

\[
(a_{pw} + b_h)(I_M u_h, z_h - I_M z_h) \leq \Lambda_{dc}A_J(1 + \Lambda_M)(1 + \Lambda_h)\|u - u_h\|_h \|z - I_M z\|_{pw}.
\]

The dual discrete consistency in (6.1) applies to the first two terms in (6.12) and leads to \(\Lambda_{ddc}\|u - u_h\|_h\times \|\zeta - I_M z_h\|_{pw}\) controlled with (5.2b) in (6.3). This with (6.2b) and (6.7) result in

\[
a_{pw}(u_h - I_M u_h, I_M z_h) + b_h(u_h, I_M z_h) \leq \Lambda_{ddc}A_J(1 + \Lambda_M)(1 + \Lambda_h)\|u - u_h\|_h \|z - I_M z\|_{pw}.
\]

The last term in (6.12) is controlled in (5.16). This and (6.7) show

\[
c_h(u_h, z_h) \leq \Lambda_c\|u - u_h\|_h \|z - z_h\|_h \leq \Lambda_c(1 + \Lambda_h)\|u - u_h\|_h \|z - I_M z\|_{pw}.
\]

A combination of the preceding four estimates with (6.11) and (6.12) concludes the proof.

\[\square\]

6.5. Proof of Theorem 6.2

Given \(2 - \sigma \leq s \leq 2\), there exists a constant \(0 < C_{int}(s) < \infty\) (which exclusively depends on the shape regularity of \(T\) and \(s\)) such that the solution \(z \in V\) of the dual problem in Section 6.2 satisfies (with Lem. 3.2c) that

\[
\|z - I_M z\|_{pw} \leq C_{int}(s)h^{2-s}_\text{max}\|\gamma\|_{H^{s-\tau}(\Omega)} \leq C_{int}(s)C_{\text{reg}}(s)h^{2-s}_\text{max}\|\Gamma\|_{H^{s-\tau}(\Omega)}.
\]

Proof of (a). Recall \(\|u - v\|_{H^s(\Omega)} = a(u - v, z)\) from Section 6.2 and its formula in Lemma 6.3. Lemma 6.4 applies to the first four terms and Lemma 6.5 to the remaining three. The resulting estimate reads

\[
\|u - v\|_{H^s(\Omega)} \leq C_6\|u - u_h\|_h \|z - I_M z\|_{pw}
\]

with \(C_6 = (1 + \Lambda_h)(4(1 + (1 + \Lambda_J)(1 + \Lambda_M)^2 + (2 + M_b)A_M^2 + (\Lambda_{dc} + \Lambda_{ddc})(1 + \Lambda_M)A_J + \Lambda_c))\). This and \(\|z - I_M z\|_{pw} \leq C_{int}(s)C_{\text{reg}}(s)h^{2-s}_\text{max}\) from (6.13) prove Theorem 6.2a. \(\square\)

Proof of (b). The norm in \(H^s(T) = \bigcap_{s \in T} H^s(T)\) is the \(l^2\) norm of those contributions \(\|\bullet\|_{H^s(T)}\) for all \(T \in \mathcal{T}\). The Sobolev–Slobodeckii semi-norm over \(\Omega\) involves double integrals over \(\Omega \times \Omega\) and so is larger than or equal
to the sum of the contributions over $T \times T$ for all the triangles $T \in \mathcal{T}$, i.e., $\sum_{T \in \mathcal{T}} |\bullet|_{H^s(T)}^2 \leq |\bullet|_{H^s(\Omega)}^2$ for any $1 < s < 2$. Hence Theorem 6.2a implies

$$\|u - JI_Mu_h\|_{H^s(T)} \leq C_4(s) h_{\max}^{2-s} \|u - u_h\|_h \quad \text{for all } s \text{ with } 2 - \sigma \leq s \leq 2. \quad (6.14)$$

Since $u_h \in P_2(T)$, Theorem 4.5d provides the estimate

$$\|u_h - JI_Mu_h\|_{H^s(T)} \lesssim h_{\max}^{2-s} \|u - u_h\|_h.$$ 

The triangle inequality in the norm of $H^s(T)$ concludes the proof of Theorem 6.2b.

\[\square\]

### 6.6. Verification of (H) and (H)̄

For the choice $P = Q = J \circ I_M$, Theorem 4.5c shows that (2.3)–(2.5) hold for all the lowest-order schemes $V_h \subseteq P_2(T)$ considered in this paper. This subsection verifies (H) and (H)̄.

**Lemma 6.6 (Verification of (H) and (H)̄).** Suppose the assumptions of Theorems 5.4 and 6.2. Any $v_h \in V_h$, $v := JI_Mv_h \in V$, $w_h \in V_h$, and $w = JI_Mw_h \in V$ satisfy

(H) $A_h(v_h, w_h) - a(v, w) \leq A_1 \|v_h - v\|_h \|w_h\|_h,$

(H)̄ $A_h(v_h, w_h) - a(v, w) \leq A_2 \|v_h - v\|_h \|w_h - w\|_h$

with $A_1 := (1 + A_M)(A_{dc} + A_1M_M\|J\|) + (1 + M_b)A_M + A_c$, and $A_2 := A_{dce} + (1 + M_b)A_M^2 + (1 + A_M)(1 + A_M + A_{dc}) + A_c.$

**Proof of (H).** For $w_M := I_Mw$, and $v_M := JI_Mv$, (3.9) implies $w_M = I_Mw_h$, and $v_M = JI_Mv_h$. The definition of $A_h(\bullet, \bullet)$, algebraic manipulations, and (5.14) result in

$$A_h(v_h, w_h) - a(v, w) = a_{pw}(v_h, w_h) + b_h(v_h, w_h) + c_h(v_h, w_h) - a(v, w)$$

$$= a_{pw}(v_h - v_M, w_h) + b_h(v_h - v_M, w_h) + a_{pw}(v_M, w_h - w_M) + b_h(v_M, w_h - w_M)$$

$$+ c_h(v_h, w_h) + a_{pw}(v_M, w_M) - a(v, w). \quad (6.15)$$

The boundedness of $a_{pw}(\bullet, \bullet)$, (5.15), (5.9), and (5.2) prove

$$a_{pw}(v_h - v_M, w_h) + b_h(v_h - v_M, w_h) \leq (1 + M_b)A_M \|v_h - v\|_h \|w_h\|_h.$$ 

The discrete consistency condition (5.13) (with $w = 0$), a triangle inequality, (5.9), and (5.2) show

$$a_{pw}(v_M, w_h - w_M) + b_h(v_M, w_h - w_M) \leq A_{dc}(1 + A_M) \|v_h - v\|_h \|w_h\|_h.$$ 

The bound in (5.16) with the choice $w = 0$ implies

$$c_h(v_h, w_h) \leq A_c \|v_h - v\|_h \|w_h\|_h.$$ 

The orthogonality condition (3.5), Lemma 3.7d, (5.9), and (5.10), result in

$$a_{pw}(v_M, w_M) - a(v, w) = a_{pw}((1 - J)v_M, Jw_M) \leq A_f(1 + A_M)M_M\|J\| \|v_h - v\|_h \|w_h\|_h.$$ 

A combination of the last four displayed estimates in (6.15) leads to the desired result.

\[\square\]
Proof of (H). An alternate split of the left-hand side of the desired estimate leads to
\[ A_h(v_h, w_h) - a(v, w) = a_{pw}(v_h - v_M, w_M) + b_h(v_h, w_M) + a_{pw}(v_h - v_M, w_h - w_M) \\
+ b_h(v_h - v_M, w_h - w_M) + a_{pw}(v_M, w_h - w_M) + b_h(v_M, w_h - w_M) \\
+ a_{pw}(v_M, w_M) - a(v, w) + c_h(v_h, w_h). \] (6.16)

The discrete consistency condition (6.1) shows
\[ a_{pw}(v_h - v_M, w_M) + b_h(v_h, w_M) \leq \Lambda_{dc} \|v - v_h\|_h \|w - w_M\|_{pw}. \]
The boundedness of \(a_{pw}(*, *)\), (5.15), and (5.9) prove
\[ a_{pw}(v_h - v_M, w_h - w_M) + b_h(v_h - v_M, w_h - w_M) \leq (1 + M_b) \Lambda^2_M \|v_h - v\|_h \|w_h - w\|_h. \]
The discrete consistency condition (5.13) and (5.2) lead to
\[ a_{pw}(v_M, w_M) - a(v, w) = -a_{pw}(v - v_M, w - w_M) \leq (1 + \Lambda_M)^2 \|v_h - v\|_h \|w_h - w\|_h. \]
The bound in (5.16) implies
\[ c_h(v_h, w_h) \leq \Lambda_c \|v_h - v\|_h \|w_h - w\|_h. \]
A substitution of the last five displayed estimates in (6.16) leads to the desired result. \qed

Remark 6.7 (Thm. 2.6 implies Thm. 6.2). For \( v := JI_M u_h \in V \), recall \( \|u - v\|_{H^1(\Omega)} = a(u - v, z) \) from Section 6.2. Theorem 2.6 applies as Lemma 6.6 holds and with (5.2) leads to \( a(u - v, z) \leq C_{qo} \|u - u_h\|_h \|z - I_M z\|_h. \)

7. Modified dGFEM

The bilinear form \( A_h(*, *) := A_{dg}(*, *) \) [2, 28] is defined, for all \( v_2, w_2 \in V_h := P_2(T) \), by
\[ A_{dg}(v_2, w_2) := a_{pw}(v_2, w_2) + b_h(v_2, w_2) + c_{dg}(v_2, w_2), \] (7.1)
\[ b_h(v_2, w_2) := -\Theta \mathcal{J}(v_2, w_2) - \mathcal{J}(v_2, w_2), \] (7.2a)
\[ \mathcal{J}(v_2, w_2) := \sum_{E \in \mathcal{E}} \int_E |\nabla p_{pw} v_2|_E : \langle D_{pw}^2 w_2 \rangle_{E} \nu_E \ ds \] (7.2b)
with \( c_{dg}(*, *) \) from (4.3) and given \(-1 \leq \Theta \leq 1\). Let the jumps \( |*|_E \) across and the averages \( \langle * \rangle_E \) at an edge \( E \in \mathcal{E} \) from Section 4.1 act componentwise. Recall from Theorem 4.1 the equivalent discrete norms \( \|*\|_h \approx \|*\|_{dg} \) in \( H^2(T) \) defined in (4.1), (4.2) and (4.4). Set \( \Theta = 1 \) (resp. \( \Theta = -1 \)) to obtain the symmetric (resp. non symmetric) interior penalty Galerkin formulation; see [39] for an alternative formulation. Appropriate positive parameters \( \sigma_1, \sigma_2 \) in (4.3) guarantee (5.1).

Lemma 7.1 (Boundedness and ellipticity of \( A_{dg}(*, *) \) [28, 39]). (a) Any \( v_2, w_2 \in P_2(T) \) satisfy \( A_{dg}(v_2, w_2) \lesssim \|v_2\|_{dg} \|w_2\|_{dg}. \) (b) For \( \Theta = -1 \) and any \( \sigma_{dg} = \sigma_1 = \sigma_2 > 0, \|v_2\|_{dg}^2 \leq A_{dg}(v_2, v_2) \) holds for all \( v_2 \in P_2(T). \) (c) For \(-1 < \Theta \leq 1 \) and a sufficiently large parameter \( \sigma_{dg} = \sigma_1 = \sigma_2 > 0, \) there exists \( \alpha > 0 \) (which depends on \( \sigma_{dg} \) and the shape regularity of \( T \)) such that \( \alpha \|v_2\|_{dg}^2 \leq A_{dg}(v_2, v_2) \) for all \( v_2 \in P_2(T). \)
Throughout this paper, the parameter $\sigma_{dG}$ is chosen to guarantee the ellipticity of $A_{dG}(\bullet, \bullet)$ in Lemma 7.1 with the short notation $\sigma_{dG} \approx 1 \approx \alpha$. The modified dGFM (5.3) seeks the solution $u_{dG} \in P_2(T)$ to

$$A_{dG}(u_{dG}, v_2) = F(JMv_2) \quad \text{for all } v_2 \in P_2(T). \quad (7.3)$$

**Theorem 7.2** (Error estimates). The solution $u \in V$ to (3.1) and the solution $u_{dG} \in P_2(T)$ to (7.3) satisfy (a) $\|u - u_{dG}\|_h \lesssim \|u - JM_u\|_{pw}$ and (b) if $\Theta = 1$ and $F \in H^{-s}(\Omega)$ for $2 - \sigma \leq s \leq 2$, then $\|u - JM_uu_{dG}\|_{H^{s}(\Omega)} + \|u - u_{dG}\|_{H^{r}(T)} \lesssim \beta_{\max}^{2-s}\|u - u_{dG}\|_h$.

**Overview of the proof.** The assertion (a) follows from Theorem 5.4 for the particular spaces, operators, norms, and bilinear forms defined below. The application of Theorem 5.4 requires the proof of the abstract conditions (5.1) and (5.2), (5.9)–(5.16). The assertion (b) follows from Theorem 6.2 provided (6.1) holds.

**Setting and first consequences.** Recall $\|\cdot\|_h$ and the norms $\|\cdot\|_{dG}$ in (4.1), (4.2) and (4.4). Recall the Morley interpolation operator $I_M$ from Definition 3.5 and the companion operator $J$ from Lemma 3.7. Recall that Lemma 7.1 guarantees (5.1) and (5.2). The dGFM in (7.3) corresponds to (5.3) with the solution $u_h := u_{dG}$. Example 5.3 implies (5.9) and (5.10). Set $I_h := id$ and observe (5.11) holds for $\Lambda_h = 0$. Recall $A_h(\bullet, \bullet) := A_{dG}(\bullet, \bullet), b_h(\bullet, \bullet) := -\Theta(J(\bullet, \bullet) - J^*(\bullet, \bullet))$, and $c_h(\bullet, \bullet) := c_{dG}(\bullet, \bullet)$ in (5.12).

**Proof of (5.13).** Since the integral $\int_E [\nabla_{pw} v_M]_E \, ds = 0$ vanishes for $v_M \in M(T)$ and since $\langle D_{pw}^2 w_2 \rangle_E$ is constant on any edge $E \in \mathcal{E}$ for any $w_2 \in P_2(T)$,

$$J(v_M, w_2) = \sum_{E \in \mathcal{E}} \int_E [\nabla_{pw} v_M]_E \cdot \langle D_{pw}^2 w_2 \rangle_E v_E \, ds = 0. \quad (7.4)$$

Hence the term $\Theta J(v_M, w_2 - I_M w_2)$ disappears below in definitions of $(a_{pw} + b_h)(\bullet, \bullet)$, written in the short notation of Section 5.5; $(a_{pw} + b_h)(v_M, w_2 - I_M w_2)$ is equal to

$$\sum_{T \in \mathcal{T}} \int_K D_{pw}^2 v_M : D_{pw}^2 (w_2 - I_M w_2) \, dx - \sum_{E \in \mathcal{E}} \int_E [\nabla_{pw} (w_2 - I_M w_2)]_E \cdot \langle D_{pw}^2 v_M \rangle_E v_E \, ds.$$

A piecewise integration by parts of the term $a_{pw}(v_M, w_2 - I_M w_2)$ shows equality to

$$\sum_{E \in \mathcal{E}} \int_E \left( \langle \nabla_{pw} (w_2 - I_M w_2) \cdot (D_{pw}^2 v_M v_E) \rangle_E - \langle \nabla_{pw} (w_2 - I_M w_2) \rangle_E \cdot \langle D_{pw}^2 v_M \rangle_E v_E \right) \, ds.$$

The product rule for the jump terms results in

$$(a_{pw} + b_h)(v_M, w_2 - I_M w_2) = \sum_{E \in \mathcal{E}} \int_E (\nabla_{pw} (w_2 - I_M w_2))_E \cdot [D_{pw}^2 v_M]_E v_E \, ds. \quad (7.5)$$

The further analysis concerns the split of the vector $\langle \nabla_{pw} (w_2 - I_M w_2) \rangle_E \in P_1(E; \mathbb{R}^2) \equiv P_1(E)^2$ into normal and tangential components,

$$\langle \nabla_{pw} (w_2 - I_M w_2) \rangle_E = \langle \partial(w_2 - I_M w_2)/\partial n \rangle_E v_E + \langle \partial(w_2 - I_M w_2)/\partial s \rangle_E \tau_E.$$

The integral of the normal component $\langle \partial(w_2 - I_M w_2)/\partial n \rangle_E$ over an edge $E \in \mathcal{E}$ vanishes by definition of $I_M w_2$ in Definition 3.5. Since the jump $[\partial_{\nu_{w_2}} v_M]_E := \nu_E \cdot [D_{pw}^2 v_M]_E v_E$ is constant along $E$, the integral $\int_E (\partial(w_2 - I_M w_2)/\partial n \rangle_E) [\partial_{\nu_{w_2}} v_M]_E \, ds = 0$ vanishes. The tangential components with $[\partial_{\tau_{w_2}} v_M]_E := \tau \cdot [D_{pw}^2 v_M]_E v_E$ remain in

$$(a_{pw} + b_h)(v_M, w_2 - I_M w_2) = \sum_{E \in \mathcal{E}} \int_E (\partial(w_2 - I_M w_2)/\partial s \rangle_E [\partial_{\tau_{w_2}} v_M]_E \, ds.$$
The Hadamard jump condition asserts that the jump in the derivative of a globally continuous function that is smooth up to the boundary on either side of an interface \( E \) points merely in the normal direction \( \nu_E \) only. The function \( J_{v_M} \) has a continuous gradient \( \nabla J_{v_M} \) and \( \nabla J_{v_M} \) is smooth on each triangle \( \hat{T} \) in the HCT refinement of \( T \). Hence \( \partial^2_{\tau_E \nu_E} J_{v_M} \) is 0 along \( E \). Consequently,

\[
(a_{pw} + b_h)(v_M, w_2 - I_M w_2) = \sum_{E \in \mathcal{E}} \int_E \langle \partial (w_2 - I_M w_2) / \partial s \rangle_E \partial^2_{\tau_E \nu_E} (1 - J) v_M \rangle_E \mathrm{d}s. \tag{7.6}
\]

For an interior edge \( E = \partial T_+ \cap \partial T_- = \partial \hat{T}_+ \cap \partial \hat{T}_- \) with the neighbouring triangles \( T_\pm \in T \) and the two neighbouring sub-triangles \( \hat{T}_\pm := \operatorname{conv}(E, \operatorname{mid}(T_\pm)) \) from the HCT refinement of \( T \) with patches \( \hat{\omega}(E) = \operatorname{int}(\hat{T}_+ \cup \hat{T}_-) \subset \omega(E) = \operatorname{int}(T_+ \cup T_-) \), Cauchy and triangle inequalities show

\[
I(E) := \int_E \langle \partial (w_2 - I_M w_2) / \partial s \rangle_E \partial^2_{\tau_E \nu_E} (1 - J) v_M \rangle_E \mathrm{d}s
\]

\[
\leq \frac{1}{2} \left( \| \nabla (w_2 - I_M w_2)|_{\partial(T)} \|_{L^2(E)} + \| \nabla (w_2 - I_M w_2)|_{\partial(T)} \|_{L^2(E)} \right)
\]

\[
\times \left( \| D^2 (1 - J) v_M \|_{\hat{T}_+} \|_{L^2(E)} + \| D^2 (1 - J) v_M \|_{\hat{T}_-} \|_{L^2(E)} \right).
\]

Since \( (w_2 - I_M w_2)|_{\hat{T}_+} \) resp. \( (1 - J) v_M |_{\hat{T}_-} \) is a polynomial of degree at most 2 resp. 3 in the triangle \( \hat{T}_\pm \) (and so on the shape regularity of \( \hat{T}_\pm \) and so on the shape regularity of \( T \)). This leads to

\[
I(E) \leq C_7 \| h_{\hat{T}_-}^{-1} \nabla_{pw} (w_2 - I_M w_2) \|_{L^2(\hat{T}_-)} \| D^2_{pw} (1 - J) v_M \|_{L^2(\hat{T}_-)}
\]

for any interior edge \( E \in \mathcal{E}(\Omega) \) with the reduced edge-patch \( \hat{\omega}(E) \). The same estimate follows for a boundary edge \( E \in \mathcal{E}(\partial \Omega) \) (the proof omits \( T_- \), \( \hat{T}_- \), and some factor \( 1/2 \) above). Since the reduced edge-patches \( \hat{\omega}(E) : E \in \mathcal{E} \) have no overlap, the sum of all the above estimates of \( I(E) \) in (7.6) and Cauchy inequalities prove

\[
(a_{pw} + b_h)(v_M, w_2 - I_M w_2) \leq C_7 \| h_{\hat{T}_-}^{-1} (w_2 - I_M w_2) \|_{H^1(\hat{\omega}(E))} \| (1 - J) v_M \|_{pw}. \tag{7.7}
\]

Recall from Theorem 4.3a (with \( \| (1 - \Pi_0) D^2_{pw} w_2 \| = 0 \) for \( w_2 \in P_2(T) \)) that

\[
\| h_{\hat{T}_-}^{-1} (w_2 - I_M w_2) \|_{H^1(\hat{T})} \lesssim j_h (w_2 - w) \lesssim \| w_2 - w \|_h
\]

for all \( w \in V \). Lemma 3.7d shows \( \| (1 - J) v_M \|_{pw} \leq \Lambda_1 \| v_M - v \|_{pw} \) for any \( v \in V \). The combination of this with (7.7) concludes the proof of (5.13).

\[\square\]

**Proof of (5.14).** This follows from (7.4).

\[\square\]

**Proof of (5.15).** This follows from the boundedness of \( b_h(\bullet, \bullet) \) (see [28, 39]).

\[\square\]

**Proof of (5.16).** The jump contributions in (4.3) vanish for arguments in \( V \), \( c_{dG}(v_2, w_2) = c_{dG}(v - v_2, w - w_2) \) on the left-hand side of (5.16). Recall that \( c_{dG}(\bullet, \bullet) \) is a semi-norm scalar product and the Cauchy inequality with the induced semi-norm \( \| \bullet \|_{c_{dG}} := c_{dG}(\bullet, \bullet)^{1/2} \leq \| \bullet \|_{dG} \) is a part of the discrete norm \( \| \bullet \|_{dG} \). This leads to (5.16) with \( \Lambda_c = 1 \).

\[\square\]

**Proof of (6.1) for \( \Theta = 1 \).** This follows from Remark 6.1.

\[\square\]
8. Modified $C^0$IP method

For the right-hand side $F \in H^{-2}(\Omega)$, the modified $C^0$IP method is based on the continuous Lagrange $P_2$ finite element space $V_h := S_0^2(T) := P_2(T) \cap H_0^1(\Omega)$ and penalty terms along edges. The scheme is a modification of the dGFEM in Section 7 but with trial and test functions restricted to finite element space.

Given $\sigma_{IP} > 0$, the bilinear forms $[6, 24]$ for $v_{IP}, w_{IP} \in S_0^2(T)$ are defined by

$$A_{IP}(v_{IP}, w_{IP}) := a_{pw}(v_{IP}, w_{IP}) + b_h(v_{IP}, w_{IP}) + c_{IP}(v_{IP}, w_{IP}), \quad (8.1)$$

and $b_h(\bullet, \bullet) = b_h(\bullet, \bullet)|_{S_0^2(T)}$ from (7.2a).

The modified $C^0$IP method is of the form (5.3) and seeks $u_{IP} \in S_0^2(T)$ such that

$$A_{IP}(u_{IP}, v_{IP}) = F(J_{IM}v_{IP}) \quad \text{for all } v_{IP} \in S_0^2(T). \quad (8.3)$$

For all $v + v_{IP} \in V + S_0^2(T)$, the discrete norm reads $\|v + v_{IP}\|_{IP} := (\|v + v_{IP}\|_{pw}^2 + c_{IP}(v_{IP}, w_{IP}))^{1/2}$ and $j_h(v_{IP}) = \langle \sum_{E \in \mathcal{E}} (\int_E \partial v_{IP}/\partial n_E \, ds)^2 \rangle^{1/2}$. Theorem 4.1 shows $\|v_{IP}\|_{h} \approx \|v_{IP}\|_{IP}$. The coercivity $\|\cdot\|_{IP} \lesssim A_{IP}(\cdot, \cdot)$ on $S_0^2(T)$ holds provided $\sigma_{IP}$ is sufficiently large $[6, 24]$. The boundedness $A_{IP}(v_{IP}, w_{IP}) \lesssim \|v_{IP}\|_{IP} \|w_{IP}\|_{IP}$ holds for all $v_{IP}, w_{IP}$ on $S_0^2(T)$ and (8.3) has a unique solution $u_{IP} \in S_0^2(T)$.

**Theorem 8.1** (Error estimates). The solution $u \in V$ to (3.1) and the solution $u_{IP} \in S_0^2(T)$ to (8.3) satisfy (a) $\|u - u_{IP}\|_{H^{s}(\Omega)} \lesssim \|u - I_M u\|_{pw}$ and (b) if $\Theta = 1$ and $F \in H^{-s}(\Omega)$ for $2 - \sigma \leq s \leq 2$, then $\|u - J_M u_{IP}\|_{H^{s}(\Omega)} + \|u - u_{IP}\|_{H^{-s}(\Omega)} \lesssim h_{\max}^{2-s} \|u - u_{IP}\|_{h}$.

**Remark 8.2.** A $C^0$IP discrete scheme is analysed in [6] for a general $F \in H^{s-2}(\Omega)$. The consistency of the scheme allows a best approximation ([6], Lem. 8) (since $V_h$ subset $H^{s-\eta}(\Omega)$ in the pure Dirichlet problem for $C^0$IP).

For $F \in H^{-2}(\Omega)$, a modified scheme and error estimates for the post-processed solution are derived in (4.17) and Theorem 4 of [6].

**Overview of the proof of Theorem 8.1.** The proof follows the lines of that of Theorem 7.2 and partly from the analysis provided there. The bilinear forms in the $C^0$IP are exactly the respective bilinear forms of the dGFEM when restricted to the subspace $S_0^2(T) + M(T)$. With the single exception of (5.11), all the estimates in (5.9)–(5.16) and (6.1) for $\Theta = 1$ follow for $V_h = S_0^2(T)$ in the $C^0$IP from the respective properties verified in Section 7 for $V_h = P_2(T)$ in the dGFEM. The remaining detail is the analysis of the operator $I_h \equiv I_C : M(T) \to S_0^2(T)$ (denoted by $I^*_h$ in Lem. 3.2 of [23]) defined by averaging the values of a function $v_M \in M(T)$ at the midpoint of an interior edge $E$,

$$(I_C v_M)(z) = \begin{cases} v_M(z) & \text{for all } z \in V, \\
(v_M)_E(z) & \text{for } z = \text{mid}(E), \ E \in \mathcal{E}(\Omega), \\
0 & \text{for } z = \text{mid}(E), \ E \in \mathcal{E}(\partial \Omega). \end{cases} \quad (8.4)$$

**Proof of (5.11).** This is included in Lemma 3.2f of [23] in a slightly different notation. In the notation of this paper, Lemma 3.2 of [23] shows

$$\|v_M - I_C v_M\|_{h}^2 \lesssim \sum_{E \in \mathcal{E}} h_E^{-2} \|v_M|_{E}(\text{mid}(E))|^2 \quad (8.5)$$
The equivalence constants independent of shape-regularity of \( \|\cdot\| \).

Theorem 9.1. Three modified schemes with \( F \) oscillations for

\[
\mathcal{T} \ni \mathcal{T}_I \mathcal{V}
\]

for any \( v \). This leads to (5.11). Theorem 4.5 allows for an alternative proof that departs at (8.5) with the quadratic function \( [v_m]_E \) along the edge \( E \in \mathcal{E} \). Since \( [v_m]_E \) vanishes at each end point \( z \in \mathcal{V}(E) \) (owing to the continuity of the Morley function \( v_m \in M(T) \) at the vertices), the (exact) Simpson’s quadrature rule asserts

\[
[v_m]_E(\text{mid}(E)) = 3/2 \int_E [v_m]_E \, ds.
\]

A Cauchy inequality, the continuity of \( Jv_m \in \mathcal{V} \), triangle and trace inequalities lead to

\[
h^2_E\|v_m\|_E(\text{mid}(E))^2 \leq \frac{9}{4} h^{-3}_E \|v_m - Jv_m\|_{L^2(E)}^2 \lesssim \sum_{t=0}^1 h^{-2}_T (v_m - Jv_m)^2_{H^s(\omega(E))}.
\]

This estimate and the finite overlap of the edge-patches \( (\omega(E) : E \in \mathcal{E}) \) lead to an upper bound in (8.5) as in Theorem 4.5c and so to \( \|v_m - ICv_m\|_h = \|v_m - v\|_h = \|v_m - v\|_{pw} \).

Remark 8.3 (\( Q \) is not injective). An illustration shall be given for a triangulation \( T = \{T_1, T_2\} \) of a convex quadrilateral \( \Omega = T_1 \cup T_2 = \text{conv}\{P_1, P_2, P_3, P_4\} \). There is exactly one basis function \( b_E \in S^2_T(T) = V_h \) defined on \( T_1 = \text{conv}\{P_1, P_2, P_3\} \) and on \( T_2 = \text{conv}\{P_2, P_3, P_4\} \) by \( b_E = 4\varphi_2\varphi_4 \) for the nodal basis functions \( \varphi_1, \varphi_2, \varphi_3, \varphi_4 \). Given \( b_E \) for the edge \( E = \text{conv}\{P_2, P_4\} = \partial T_1 \cap \partial T_2 \), the normal derivative of \( b_E \) along \( E \) on \( T_1 \) reads in its integral

\[
\int_E \partial b_E|_{T_1}/\partial \nu_E \, ds = \nu_E \cdot \int_E \nabla b_E|_{T_1} \, ds = 4\nu_E \cdot \int_E (\varphi_2 \nabla \varphi_4|_{T_1} + \varphi_4 \nabla \varphi_1|_{T_1}) \, ds
\]

with \( \nabla (\varphi_1 + \varphi_2 + \varphi_4) = 0 \) in \( T_1 \) in the last step. Elementary geometry shows \( \nabla \varphi_1|_{T_1} = \nu_E / \rho_{E,1} \) for the height \( \rho_{E,1} = \frac{2|T_1|}{|E|} \) of \( E \) in \( T_1 \) and \( \nu_E \) pointing from \( T_1 \) into \( T_2 \). Consequently, \( \int_E \partial b_E|_{T_1}/\partial \nu_E \, ds = \frac{|E|^2}{|T_1|^2} \). The analogous calculation for \( T_2 \) leads to \( \int_E \partial b_E|_{T_2}/\partial \nu_E \, ds = -\frac{|E|^2}{|T_2|^2} \) with a change of sign because \( \nabla \varphi_3|_{T_2} = \nu_E / \rho_{E,2} \).

The definition of \( I_M b_E \) takes the average of the two integral means

\[
\frac{1}{2} \left( \int_E \partial b_E|_{T_1}/\partial \nu_E + \int_E \partial b_E|_{T_2}/\partial \nu_E \right) \, ds = \frac{|E|}{2} \left( |T_1|^{-1} - |T_2|^{-1} \right)
\]

as the value for \( \int_E \partial I_M b_E/\partial \nu_E \, ds \). Since this is the only degree of freedom in \( M(T) \) for the triangulation \( T = \{T_1, T_2\} \), it follows that \( I : S^2_T(T) \rightarrow M(T) \) is injective if and only of \( |T_1| = |T_2| \). (This condition is independent of shape-regularity of \( T \) and thus more involved.)

9. Comparison

The paper [23] has established equivalence of discrete solutions to Morley FEM, \( C^0 \)IP and dGFEM up to oscillations for \( F \in L^2(\Omega) \) and for the original schemes with \( F_h \equiv F \). The subsequent theorem establishes the three modified schemes with \( F_h = F \circ J \) without extra oscillation terms. Throughout this section, the norm \( \|\cdot\|_h \) is defined in (4.1) and (4.2).

Theorem 9.1. The discrete solutions \( u_M, u_{IP} \) and \( u_{dG} \) of the Morley FEM, \( C^0 \)IP and dGFEM satisfy

\[
\|u - u_M\|_h \approx \|u - u_{dG}\|_h \approx \|u - u_{IP}\|_h \approx \|1 - \Pi_0\|D^2u\|L^2(\Omega).
\]

The equivalence constants \( \approx \) depend on shape regularity and on the stabilisation parameters \( \sigma_{dG}, \sigma_{IP} \approx 1 \).
Remark 9.2 (Discrete dG norm equivalence, Theorem 4.1, [23]). The norm \( \| \cdot \|_h \) satisfies
\[
\| \cdot \|_h = \| \cdot \|_{\text{pw}} \quad \text{on} \quad V + M(T),
\| \cdot \|_h \approx \| \cdot \|_{\text{dG}} \quad \text{on} \quad V + P_2(T),
\| \cdot \|_h \approx \| \cdot \|_{\text{IP}} \quad \text{on} \quad V + S^2_0(T).
\]

Proof. Lemma 3.2a, the Pythagoras identity, and Theorem 2.2 of [16] show
\[
\text{Proof. Lemma 3.2a, the Pythagoras identity, and Theorem 2.2 of [16] show}
\]
\[
\text{Lemma 3.2a, the Pythagoras identity, and Theorem 2.2 of [16] show}
\]
\[
Theorem 10.1 leads to similar results for \( \| u - u_{\text{IP}} \|_h \). A combination of the above displayed inequalities concludes the proof. \( \square \)

10. Modified WOPSIP Method

The weakly over-penalized symmetric interior penalty (WOPSIP) scheme [7] is a penalty method with the stabilisation term
\[
c_P(v_{\text{pw}}, w_{\text{pw}}) := \sum_{E \in \mathcal{E}} \sum_{z \in \partial(E)} h_E^{-4} (|v_{\text{pw}}|_E(z)) (|w_{\text{pw}}|_E(z))
+ \sum_{E \in \mathcal{E}} h_E^{-2} \left( \int_E [\partial v_{\text{pw}}/\partial \nu_E]_E \, ds \right) \left( \int_E [\partial w_{\text{pw}}/\partial \nu_E]_E \, ds \right)
\]
for piecewise smooth functions \( v_{\text{pw}}, w_{\text{pw}} \in H^2(T) \). This semi-norm scalar product \( c_P(\cdot, \cdot) \) is an analog to that one behind the jump \( j_h \) from (4.2) with different powers of the mesh-size. It follows as in Theorem 4.1 that
\[
A_P(v_{\text{pw}}, w_{\text{pw}}) := a_P(v_{\text{pw}}, w_{\text{pw}}) + c_P(v_{\text{pw}}, w_{\text{pw}}) \quad \text{for all} \quad v_{\text{pw}}, w_{\text{pw}} \in H^2(T)
\]
defines a scalar product and so \( \| \cdot \|_P := A_P(\cdot, \cdot)^{1/2} \) is a norm in \( H^2(T) \). Consequently, there exists a unique solution \( u_P \in V_h := P_2(T) \) to
\[
A_P(u_P, v_2) = F(JI_Mv_2) \quad \text{for all} \quad v_2 \in P_2(T).
\]

The increased condition number in the over-penalization of the jumps by the negative powers of the mesh-size in (10.1) can be compensated by some preconditioner ([7], p. 218f) and the entire WOPSIP linear algebra with (10.3) becomes intrinsically parallel.

Theorem 10.1 (Error estimate). Any \( F \in H^{-s}(\Omega) \) with \( 2 - \sigma \leq s \leq 2 \), the solution \( u \in V \) to (3.1) and the solution \( u_P \in P_2(T) \) to (10.3) satisfy
\[
\| u - u_P \|_{\text{pw}}^2 + c_P(u_P, u_P) \leq (1 + \Lambda_P^2) \| u - I_Mu \|_{\text{pw}}^2 + \Lambda_P^2 \| h_T I_Mu \|_{\text{pw}}^2;
\| u - JI_Mu_P \|_{H^s(\Omega)} + \| u - u_P \|_{H^s(T)} \leq C_8(\| s \|) h_{\text{max}}^{2-s} \| u - u_P \|_P.
\]
The constant \( \Lambda_P \) exclusively depends on the shape regularity of \( T \), while \( C_8 \) depends on the shape regularity of \( T \) and on \( s \).
Lemma 10.2. There exists some positive \( \Lambda_P < \infty \), that exclusively depends on the shape regularity of \( T \), such that
\[
\| h_T^{-1}(v_2 - I_M v_2) \|_{pw}^2 + \| (1 - J) I_M v_2 \|_{pw}^2 \leq \Lambda_P^2 \| v_2 - v \|_P^2
\]
holds for all \( v_2 \in P_2(T) \) and all \( v \in V \).

Proof of Lemma 10.2. The analysis of \( \| h_T^{-1}(v_2 - I_M v_2) \|_{pw} \) returns to the proof of Theorem 4.3 that eventually provides (4.11) for one fixed triangle \( T \in \mathcal{T} \) with its neighbourhood \( \Omega(T) \) for any \( v_2 \in P_2(T) \). The substitution of \( v_2 \) by \( h_T^{-1}v_2 \) (with a fixed scaling factor \( h_T \)) in (4.11) after a standard inverse estimate shows, for all \( v_2 \in P_2(T) \), that
\[
h_T^{-2} |v_2 - I_M v_2|_{H^2(T)}^2 \lesssim h_T^{-6} \| v_2 - I_M v_2 \|_{L^2(T)}^2 \lesssim j_h(h_T^{-1}v_2, T)^2.
\]
The shape regularity of \( T \) implies that all edge-sizes in the sub-triangulation \( \mathcal{T}(\Omega(T)) \) that covers the neighbourhood \( \Omega(T) \) (of \( T \) and one layer of triangles around \( T \)) are equivalent to \( h_T \). Hence \( j_h(h_T^{-1}v_2, T) \) is equivalent to the respective contributions in \( c_P(v_2, v_2) \):
\[
j_h(h_T^{-1}v_2, T)^2 \lesssim \sum_{z \in \mathcal{V}(T)} \sum_{E \in \mathcal{E}(z)} h_F^{-4}([v_2]_F(z))^2 + \sum_{E \in \mathcal{E}(T)} h_E^{-2} \left( \int_E |\partial v_{pw}/\partial v_E| ds \right)^2.
\]

The combination of this estimate with the previous one and the sum over all those estimates lead to
\[
\| h_T^{-1}(v_2 - I_M v_2) \|_{pw}^2 \lesssim c_P(v_2, v_2)
\]
(10.4) owing to the finite overlap of the family \( \{\Omega(T) : T \in \mathcal{T}\} \). The second term \( \| (1 - J) I_M v_2 \|_{pw} \) is controlled with Lemma 3.7d and a triangle inequality in
\[
\Lambda_P^{-1} \| (1 - J) I_M v_2 \|_{pw} \leq \| v - I_M v_2 \|_{pw} \leq \| v - v_2 \|_{pw} + \| v_2 - I_M v_2 \|_{pw}.
\]
Since the the last term \( \| v_2 - I_M v_2 \|_{pw} \lesssim h_{\text{max}} \| h_T^{-1}(v_2 - I_M v_2) \|_{pw} \) is bounded in (10.4), the summary of the aforementioned estimates concludes the proof of the lemma.

Proof of energy norm estimate in Theorem 10.1. The equations (3.1) and (10.3) show the key identity
\[
a(u, J_M e_P) = F(J_M e_P) + c_P(u_P, e_P)
\]
for \( e_P := I_M u - u_P \in P_2(T) \).

Remark 4.2 applies verbatim and provides \( c_P(I_M u, e_P) = 0 \). This, the key identity, and the definition of the norm \( \| \bullet \|_P := A_P(\bullet, \bullet)^{1/2} \) lead to
\[
\| e_P \|_P^2 = a_{pw}(I_M u, e_P) - a(u, J_M e_P) = a_{pw}(u, e_P - J_M e_P)
\]
(10.5) with (3.5) in the last step. Set \( e_M := I_M e_P \in M(T) \) and split \( e_P - J_M e_P = (e_P - e_M) + (1 - J)e_M \). The last term in (10.5) is equal to
\[
\begin{align*}
a_{pw}(u, e_P - e_M) + a_{pw}(u, e_M - J e_M) &= a_{pw}(I_M u, e_P - e_M) + a_{pw}(u - I_M u, e_M - J e_M) \\
&\leq \| h_T I_M u\|_{pw} \| h_T^{-1}(e_P - e_M)\|_{pw} + \| u - I_M u\|_{pw} \| e_M - J e_M\|_{pw} \\
&\leq \Lambda_P \left( \| h_T I_M u\|_{pw}^2 + \| u - I_M u\|_{pw}^2 \right)^{1/2} \| e_P \|_P
\end{align*}
\]
with (3.5) twice in the first equality, (weighted) Cauchy inequalities for the inequality in the third line, and Lemma 10.2 (with \( v = 0 \)) in the end. The combination with (10.5) proves
\[
\| e_P \|_P^2 \leq \Lambda_P^2 \left( \| h_T I_M u\|_{pw}^2 + \| u - I_M u\|_{pw}^2 \right).
\]
This and the Pythagoras theorem (3.7) conclude the proof.
Proof of error estimates in weaker (piecewise) Sobolev norms in Theorem 10.1. The error analysis in weaker norms adapts the notation of the beginning of Section 6.2 on $v := JI_M u_p \in V$ and $\zeta := JI_M z \in V$ for the dual solution $z \in V$ with $\|z\|_{H^{s-\epsilon}(\Omega)} \leq C_{\text{reg}}$ and

$$\|u - v\|_{H^{s-\epsilon}(\Omega)} = a(u - v, z) = a(u, z - \zeta) + a_{pw}(u_p - v, z)$$

with the key identity $a(u, \zeta) = F(\zeta) = A_p(u_p, I_M z) = a_{pw}(u_p, I_M z) = a_{pw}(u_p, z)$ (from Rem. 4.2 and (3.5)) in the last step. Since $a_{pw}(I_M u, z - \zeta) = 0$ (from (3.5) with $I_M z = I_M \zeta$ from (3.9)), the first term

$$a(u, z - \zeta) = a_{pw}(u - I_M u, z - \zeta) \leq (1 + \Lambda_3)(1 + \Lambda_5)\|u - I_M u\|_{pw}\|z - I_M z\|_{pw}$$

is controlled by (6.5) (with $z_h = I_M z$, $I_h = \text{id}$). The analysis of the second term $a_{pw}(u_p - v, \zeta)$ follows the corresponding lines of the proof of the best-approximation in Theorem 10.1 with $u_M := I_M u$, $u_p - v = u_p - u_M + (1 - J)u_M$. This shows

$$a_{pw}(u_p - v, \zeta) = a_{pw}(u_p - u_M, z) + a_{pw}(u_M - J u_M, z)$$

$$\leq \|h_T I_M z\|_{pw} \|h_T^{-1}(u_p - u_M)\|_{pw} + \|z - I_M z\|_{pw} \|u_M - J u_M\|_{pw}$$

$$\leq \Lambda_5 \left(\|h_T I_M z\|_{pw}^2 + \|z - I_M z\|_{pw}^2\right)^{1/2} \|u - u_p\|_p$$

from Lemma 10.2 with $v = u$. The final argument is the regularity of $z$ and the approximation estimates $\|z - I_M z\|_{pw} \leq C_{\text{int}}(s) C_{\text{reg}}(s) h^{2-s}$ from Section 6.5. The combination of the above arguments shows

$$\|u - JI_M u_p\|_{H^{s-\epsilon}(\Omega)} \lesssim h^{2-s}\|u - u_p\|_p.$$ 

Theorem 4.5d applies to $u_p \in P_2(\mathcal{T})$ and the remaining arguments follow the last lines in the proof Theorem 6.2b with a triangle inequality in $H^s(\mathcal{T})$ in the end. \qed

Appendix A.

Proof of Lemma 2.2. For $z \in Y_h \cap Y$, (2.2) implies $\|z - Q z\|_\phi = 0$, and hence (2.3) holds. The converse is a consequence of the finite dimension of $Y_h$. In the context of Peetre–Tartar lemma [40], let $\tilde{Y} := (1 - Q)(Y_h) \subset \tilde{Y}$ denote the range of $1 - Q$ and abbreviate $A := 1 - \Pi_Y$ and $B := \Pi_Y$. Then $A \tilde{y} = 0$ means $\tilde{y} \in \tilde{Y} \cap Y$ for some $y_h \in Y_h$ with $\tilde{y} = (1 - Q) y_h$, whence $y_h \in Y_h \cap Y$ and $\tilde{y} = 0$ from (2.2). Notice that $B \subset L(\tilde{Y}; Y)$ is compact (for $\tilde{Y}$ has finite dimension). Since $\tilde{y} = A\tilde{y} + B\tilde{y}$ implies $\|\tilde{y}\|_\phi \leq \|A\tilde{y}\|_\phi + \|B\tilde{y}\|_\phi$ for all $\tilde{y} \in \tilde{Y}$, the Peetre–Tartar lemma proves $\gamma \|\tilde{y}\|_\phi \leq \|A\tilde{y}\|_\phi$ for all $\tilde{y} \in \tilde{Y}$ and some constant $\gamma > 0$. This implies for all $y_h \in Y_h$ that

$$\gamma \|y_h - Q y_h\|_\phi \leq \|A(y_h - Q y_h)\|_\phi = \|y_h - \Pi_Y y_h\|_\phi \leq \|y_h - y\|_\phi$$

for all $y$. This is (2.3) with $\Lambda_Q := 1/\gamma > 0$. The point in those compactness arguments is that we do know that $\gamma = 1/\Lambda_Q > 0$ with (2.3) exists, but we do not know how it depends, e.g., on $\dim Y_h$. \qed

Proof of Lemma 2.4. It is obvious that (QO) implies (2.4). The converse follows from a compactness argument from $\dim X_h < \infty$. The subspace $\hat{X} := (1 - M) X \subset \hat{X}$ is complete because $1 - M : (X_h \cap \hat{X})^\perp \cap X \subset \hat{X}$ is linear, bounded, and bijective for the (complete) orthogonal complement $(X_h \cap \hat{X})^\perp \cap X$ of $X_h \cap X$ in $X$. Then $A := 1 - \Pi_{X_h} \subset L(\hat{X}; \hat{X})$ is injective (as $A\tilde{x} = 0$ implies $\tilde{x} = (1 - M)x \in X_h$, whence $x \in X_h \cap X$ and $\tilde{x} = 0$ in $\hat{X}$ from (2.4)). Since $B := \Pi_{X_h} \subset L(\hat{X}; \hat{X})$ is compact and $\tilde{x} = A\tilde{x} + B\tilde{x}$ implies

$$\|\tilde{x}\|_\hat{X} \leq \|A\tilde{x}\|_\hat{X} + \|B\tilde{x}\|_\hat{X}$$

for all $\tilde{x} \in \hat{X}$,
the Peetre–Tartar lemma [40] leads to some $\gamma > 0$ with

$$\gamma \|(1 - M)x\|_{\widetilde{X}} \leq \|A(1 - M)x\|_{\widetilde{X}} = \|x - \Pi_{X_h} x\|_{\widetilde{X}} \leq \|x - x_h\|_{\widetilde{X}}$$

for all $x \in X$ and $(1 - M)x \in \widetilde{X}$ and for all $x_h \in X_h$. This is (QO) with $C_{qo} := 1/\gamma$. \(\square\)

**Proof of Theorem 2.5.** [Proof of “\(\implies\)”] Suppose $M$ satisfies (QO) with constant $C_{qo}$. Then for all $x_h, y_h$, the definition of $MPx_h$ leads to the identity

$$a_h(x_h, y_h) - a(Px_h, Qy_h) = a_h(x_h - MPx_h, Qy_h) = \langle Q^* A_h(x_h - MPx_h), y_h \rangle_{Y_h^* \times Y_h}$$

$$\leq \|Q^* A_h\| \|y_h\|_{Y_h} \|x_h - MPx_h\|_{X_h}.$$ 

It remains to prove that $\|x_h - MPx_h\|_{X_h} \leq (1 + C_{qo}) \|x_h - Px_h\|_{\widetilde{X}}$. This follows from a triangle inequality $\|x_h - MPx_h\|_{X_h} \leq \|x_h - Px_h\|_{\widetilde{X}} + \|Px_h - MPx_h\|_{\widetilde{X}}$ and (QO) in $\|Px_h - MPx_h\|_{\widetilde{X}} \leq C_{qo} \|Px_h - x_h\|_{\widetilde{X}}$. In conclusion, (H) holds with $A_h := \|Q^* A_h\|(1 + C_{qo})$.

[Proof of “\(\impliedby\)”] Let $\Pi_{X_h} \in L(\widetilde{X})$ denote the orthogonal projection onto the closed subset $X_h$ in the Hilbert space $\widetilde{X}$. Given any $x \in X$, let $x_h := \Pi_{X_h} x = \arg\min_{\xi_h \in X_h} \|x - \xi_h\|_{\widetilde{X}}$ denote the best-approximation of $x$ in $X_h$ in the Hilbert space $\widetilde{X}$ and set $e_h := x_h - Mx \in X_h$. The inf-sup condition for $a_h(\bullet, \bullet)$ leads to $y_h \in Y_h$ with norm $\|y_h\|_{Y_h} \leq 1$ such that

$$a_h(e_h, y_h) = a_h(x_h, y_h) - a_h(Mx, y_h).$$

Recall the definition of $x_h := Mx = A_h^{-1} Q^* Ax$ as the discrete solution for the right-hand side $a(x, Q \bullet)$ to verify

$$a_h(Mx, y_h) = a_h(x_h, y_h) = a(x, Qy_h).$$

This leads to the identity

$$a_h(e_h, y_h) = a_h(x_h, y_h) - a(x, Qy_h).$$

(A.1)

Hypothesis (H) and $\|y_h\|_{Y_h} \leq 1$ lead to the first and (2.5) to the last inequality in

$$a_h(x_h^*, y_h) - a(Px_h^*, Qy_h) \leq \Lambda_h \|x_h^* - Px_h^*\|_{\widetilde{X}} \leq \Lambda_h A_P \|x - x_h^*\|_{\widetilde{X}}.$$ 

(A.2)

A triangle inequality and (2.5) imply

$$\|x - Px_h^*\|_{X} \leq \|x - x_h^*\|_{\widetilde{X}} + \|x_h^* - Px_h^*\|_{\widetilde{X}} \leq (1 + A_P) \|x - x_h^*\|_{\widetilde{X}}.$$ 

With the operator norm $\|Q^* A\|$ in $L(X; Y_h^*)$ and the duality brackets $\langle \bullet, \bullet \rangle_{Y_h^* \times Y_h}$ in $Y_h^* \times Y_h$, this and $\|y_h\|_{Y_h} \leq 1$ show

$$a(Px_h^* - x, Qy_h) = \langle Q^* A(Px_h^* - x), y_h \rangle_{Y_h^* \times Y_h} \leq \|Q^* A\|(1 + A_P) \|x - x_h^*\|_{\widetilde{X}}.$$ 

(A.3)

The combination of (A.1)–(A.3) reads

$$a_h(e_h, y_h) \leq (\Lambda_h A_P + \|Q^* A\|(1 + A_P)) \|x - x_h^*\|_{\widetilde{X}}.$$ 

Define $C_{qo} := 1 + a_h^{-1}(\Lambda_h A_P + \|Q^* A\|(1 + A_P))$ and rewrite the last estimate as

$$\|Mx - x_h\|_{X_h} = \|e_h\|_{X_h} \leq (C_{qo} - 1) \|x - x_h^*\|_{\widetilde{X}}.$$ 

(A.4)

A triangle inequality $\|x - Mx\|_{\widetilde{X}} \leq \|x - x_h^*\|_{\widetilde{X}} + \|Mx - x_h^*\|_{X_h}$ and (A.4) prove (QO) because of $\|x - x_h^*\|_{\widetilde{X}} = \min_{e_h \in X_h} \|x - x_h\|_{\widetilde{X}}$. \(\square\)
Proof of Theorem 2.6. [Proof of \(\implies\)] Given \(x_h' \in X_h^\perp\), let \(N := \text{Ker } M \subset X\); and let \(N^\perp\) denote the orthogonal complement of \(N\) in the Hilbert space \(X\). The restriction \(M|_{N^\perp} : N^\perp \rightarrow X_h^\perp\) of \(M\) is linear, bounded, and bijective and hence has a linear and bounded inverse \(S := (M|_{N^\perp})^{-1} : X_h^\perp \rightarrow N^\perp\). Since \(N\) is closed in \(\hat{X} = X + X_h\), the orthogonal projection \(\Pi_N \in L(\hat{X})\) onto \(N\) is well-defined and so is its restriction \(\Pi_{N|X_h^\perp} \in L(X_h^\perp; X)\). Given \(S \in L(X_h^\perp; X)\) and \(\Pi_{N|X_h^\perp}\), define \(P' := \Pi_N + S \in L(X_h^\perp; X)\). Let \(x := P'x_h' = 1 + \Pi_{N|X_h^\perp} Sx_h' \in X\) and observe \(MX = M_{|N^\perp}(Sx_h') = x_h' + MPx_h' = \text{id}\) in \(X_h^\perp\). Let \(\xi := \Pi x_h' \in X\) be the best-approximation of \(x_h'\) in \(X\) with respect to the norm of \(\hat{X}\). Since \(\xi - P'M\xi \in N \perp x_h' - P'x_h' \in N^\perp\), the Pythagoras theorem in \(\hat{X}\) reads

\[
\|\xi - x_h' + P'(x_h' - M\xi)\|_{\hat{X}}^2 = \|x_h' - Px_h'\|_{X}^2 + \|\xi - P'M\xi\|_{\hat{X}}^2.
\]

The left-hand side of the above displayed equality is an upper bound of \(\|x_h' - Px_h'\|_{X}^2\) and is smaller than or equal to the square of

\[
\|\xi - x_h' + P'(x_h' - M\xi)\|_{\hat{X}} \leq \|(1 - \Pi_{X})x_h'\|_{\hat{X}} + \|P'\|\|x_h' - M\xi\|_{X_h}\]

with the operator norm \(\|P'\|\) of \(P' \in L(X_h^\perp; X)\). Consequently,

\[
\|x_h' - Px_h'\|_{X} \leq \|(1 - \Pi_{X})x_h'\|_{\hat{X}} + \|P'\|\|x_h' - M\xi\|_{X_h}.
\]

A triangle inequality and (QO) with \(\|\xi - M\xi\|_{\hat{X}} \leq C_{qo}\|\xi - x_h'\|_{\hat{X}}\) show

\[
\|x_h' - M\xi\|_{X_h} \leq \|\xi - x_h'\|_{\hat{X}} + C_{qo}\|\xi - x_h'\|_{\hat{X}} = (1 + C_{qo})\|\xi - x_h'\|_{\hat{X}}.
\]

The combination of the previous two displayed estimates with \(\|(1 - \Pi_{X})x_h'\|_{\hat{X}} \leq \|x_h' - Px_h'\|_{\hat{X}}\) (from \(Px_h' \in X\) and the definition of \(\Pi_{X}x_h\)) and \(\Lambda_{P'} := 1 + \|P'\|\) proves

\[
\|x_h' - P'x_h'\|_{\hat{X}} \leq \Lambda_{P'}\|x_h' - Px_h'\|_{\hat{X}}. \tag{A.5}
\]

This and \(y := Qy_h \in Y\) lead in (QO) to

\[
a(P'x_h' - PMP'x_h', Qy_h) \leq \widehat{C_{qo}}\|x_h' - P'x_h'\|_{\hat{X}}\|y_h - Qy_h\|_{\hat{F}}.
\]

Recall the definition of \(x_h = Mx = A_h^{-1}Q^*Ax\) as the discrete solution to the right-hand side \(a(x, Q\bullet)\) to verify \(a_h(Mx, y_h) = a_h(x_h, y_h) = a(x, Qy_h)\). The combination with the last displayed inequality with \(MP'x_h' = x_h'\) leads to

\[
a(P'x_h' - MP'x_h', Qy_h) = a_h(x_h', y_h) - a(Px_h', Qy_h) \leq \widehat{C_{qo}}\|x_h' - P'x_h'\|_{\hat{X}}\|y_h - Qy_h\|_{\hat{F}}.
\]

This and (A.5) prove (H) with \(\widehat{\Lambda_H} = \widehat{C_{qo}}\Lambda_{P'} = \widehat{C_{qo}}(1 + \|P'\|\)\).

[Proof of \(\Leftarrow\)] Given any \(x \in X\) and \(y_h \in Y_h\), let \(x_h' := Mx \in X_h\) with \(a_h(x_h', y_h) = a(x, Qy_h)\). This shows in (H) that

\[
a(x - PMx, Qy_h) \leq \Lambda'\|x_h' - P'x_h'\|_{\hat{X}}\|y_h - Qy_h\|_{\hat{F}}.
\]

This and the operator norm \(\|a\|\) of \(a(\bullet, \bullet)\) show

\[
a(x - PMx, y) = a(x - PMx, y - Qy_h) + a(x - PMx, Qy_h)
\]

\[
\leq \|a\|\|x - PMx\|_{X}\|y - Qy_h\|_{Y} + \Lambda'\|Mx - PMx\|_{\hat{X}}\|y_h - Qy_h\|_{\hat{F}}.
\]

This and the elementary inequalities

\[
\|x - PMx\|_{X} \leq \|x - Mx\|_{\hat{X}} + \|Mx - PMx\|_{\hat{X}}, \quad \|Mx - PMx\|_{\hat{X}} \leq \Lambda_P\|x - Mx\|_{\hat{X}},
\]

and

\[
\|y - Qy_h\|_{Y} \leq \|y - y_h\|_{\hat{F}} + \|y_h - Qy_h\|_{\hat{F}}, \quad \|y_h - Qy_h\|_{\hat{F}} \leq \Lambda_{Q}\|y - y_h\|_{\hat{F}}
\]

conclude the proof of (QO) with \(\widehat{C_{qo}} := \|a\|(1 + \Lambda_P)(1 + \Lambda_Q) + \Lambda'\Lambda_P\Lambda_Q\).
