Fig. 1. (A) Pelvic axial fat-saturated T2-weighted and (B) T2-weighted magnetic resonance imaging (MRI) reveal that the ischiofemoral space is narrower on the left side than on the right side. Additionally, on the pelvic axial fat-saturated T2-weighted MRI (A), high signal intensity is found on the left quadratus femoris muscle (green arrow), indicative of muscle edema. Over the area of high signal intensity in the left quadratus femoris muscle, the left sciatic nerve is visible (yellow arrow).
triamcinolone, 1-mL 1% lidocaine, and 3.5-mL normal saline was administered via ultrasound-guided injection to the left sciatic nerve and quadratus femoris muscle. The patient’s pain was alleviated by 80% at the 3-week follow-up examination.

Ischiofemoral impingement is an uncommon cause of buttock pain due to impingement of the quadratus femoris muscle between the lesser trochanter and lateral border of the ischium [1-3]. Most patients with ischiofemoral impingement experience buttock pain [1-3]. Neuropathic pain radiating towards the posterior aspect, calf, and foot can occur due to irritation of the adjacent sciatic nerve. There are only a few reports on the diagnosis and treatment of this condition. When conservative treatments with activity modification, stretching of the hip muscles, and ischiofemoral space injection are ineffective, surgical treatment (resection of the lesser trochanter) can be considered [1-3].

In the present case, pain throughout the left foot was caused by ischiofemoral impingement. Clinicians should consider this possibility in patients with neuropathic pain radiating to the area innervated by the sciatic nerve, combined with buttock pain and aggravated by hip motion.

Learning points

- Ischiofemoral impingement can cause buttock pain with or without sciatica due to irritation of the adjacent sciatic nerve, which is caused by impingement of the quadratus femoris muscle between the lesser trochanter and lateral border of the ischium.
- Edema and a narrowed ischiofemoral space identified by pelvic MRI indicate ischiofemoral impingement.
- For ischiofemoral impingement, conservative treatment with activity modification and ischiofemoral space injection can be attempted. In cases that are refractory to conservative treatment, surgical treatment should be considered.

Notes

Ethical statements
This study was approved by the Institutional Review Board (IRB) of Yeungnam University Hospital (IRB No: 2022-07-029). Written informed consent was obtained for the publication of this report.

Conflicts of interest
Mathieu Boudier-Revéret has been editorial board member of Journal of Yeungnam Medical Science (JYMS) since 2021. Min Cheol Chang has been Associate editor of JYMS since 2021. They were not involved in the review process of this manuscript. Otherwise, there is no conflict of interest to declare.

Funding
None.
