Abstract—Traditional visible light positioning (VLP) systems estimate receivers’ coordinates based on the known light-emitting diode (LED) coordinates. However, the LED coordinates are not always known accurately. Because of the structural changes of the buildings due to temperature, humidity or material aging, even measured by highly accurate laser range finders, the LED coordinates may change unpredictably. In this paper, we propose an easy and low-cost method to update the position information of the LEDs. We use two optical angle-of-arrival (AOA) estimators to detect the beam directions of the LEDs. Each AOA estimator has four differently oriented photodiodes (PDs). Considering the additive noises of the PDs, we derive the closed-form error expression for the proposed LED coordinates estimator. Both analytical and Monte Carlo experimental results show that the layout of the AOA estimators could affect the estimation error. These results may provide intuitive insights for the design of the optical indoor positioning systems.

I. INTRODUCTION

VLP systems have aroused increasing attention from researchers for their high accuracy and low cost when light-of-sight channels exist. VLP algorithms had been roughly classified into three categories [1]: received signal strength (RSS), time of arrival (TOA) or time difference of arrival (TDOA), and angle of arrival (AOA).

Among different VLP algorithms, AOA has become one of the most popular topics. In the AOA-based systems, the transmitters or receivers are usually specially structured to detect the incident light directions, and these direction informations are combined to estimate the position of the receiver. In [2], an image sensor was exploited at the receiver to detect the signals from several beacon LEDs at the transmitter, and based on these signals, the receiver was localized. However, a drawback of image sensors is their narrow bandwidth, which hampers their applications in high rate visible light communication (VLC) systems. Reference [3], [4] proposed a quadrant photodiode angular diversity aperture (QADA) as an AOA estimator to obtain the incident light direction to the receiver. In [5], the optimal arrangement of PDs was derived for the AOA estimator to achieve the incidence vector from the receiver to the beacon LED. Although realized through various techniques, aforementioned positioning systems demand accurate coordinate informations of the beacon LEDs.

In this paper, to cover the loophole of the traditional VLP systems, we aim to propose an efficient LED coordinates estimator. Such an estimator consists of two AOA estimators in [5], and the locations of AOA estimators are premeasured. Each AOA estimator could estimate the incident vector from the AOA estimator to the LED. The main contributions of this work can be summarized as follows:

- An efficient LED localization system is proposed to avoid laborious measurement works with laser range finders.
- Both thermal noise and shot noise are considered to analyze the performance of the AOA estimator.
- Closed-form error expression is derived for the proposed LED localization system, providing a useful mathematical tool for the error analysis of such systems.

II. SYSTEM MODEL

A. Beacon LED Localization System

As shown in Fig. 1, a beacon LED is placed on the ceiling with its three-dimensional (3D) coordinates denoted by a $3 \times 1$ vector $\mathbf{t}$. Two AOA estimators have their 3D coordinates at $\mathbf{a}_1$ and $\mathbf{a}_2$. Two normalized incidence vectors are oriented from the AOA estimators to the LED, which are $\mathbf{r}_k = (\mathbf{t} - \mathbf{a}_k)/\|\mathbf{t} - \mathbf{a}_k\|$ $(k = 1, 2)$. The AOA estimators could provide the incidence vector samples $\mathbf{r}_1$ and $\mathbf{r}_2$, where $\mathbf{r}_k$ is the estimation of $\mathbf{r}_k$. Therefore, the proposed localization system is to design a function $g(\cdot)$ that can output the estimation of the LED coordinates $\hat{\mathbf{t}}$, i.e.

$$\hat{\mathbf{t}} = g(\mathbf{a}_1, \mathbf{a}_2, \mathbf{r}_1, \mathbf{r}_2).$$

(1)
The relation in (1) will be developed in the latter context, and the estimation error $\|\mathbf{t} - \hat{\mathbf{t}}\|$ will also be analyzed.

B. Lambertian Model and the Received Signal

Lambertian model is a widely used model for describing the radiation of LEDs. As shown in Fig. 2, a beacon LED emits its
Fig. 1. Demonstration of the beacon LED localization system. The LED is placed on the ceiling whose unknown 3D coordinates are denoted by \( t \). Two AOA estimators are set on the ground whose 3D coordinates are denoted by \( a \) and \( a_g \). The incidence vectors from the AOA estimators to the beacon LED are denoted by \( r; \) and \( r_g \). Each AOA estimator consists of four PDs. The normalized normal vector of each PD is \( \mathbf{v}_z.g \) (\( k = 1,2 \) \( q = 1,2,3,4 \)).

Fig. 2. Demonstration of Lambertian radiation model. \( \theta \) is the radiation angle of the beacon LED and \( \phi \) is the incidence angle of the PD. \( d \) is the distance between the LED and the PD.

Light to a PD with the radiation angle \( \theta \). The distance between the LED and the PD is \( d \), and the incidence angle of the light beam is \( \phi \). According to the Lambertian model, the received power is expressed as [6]

\[
P_r = P_t \left( \frac{m + 1}{2\pi d^2} \right) \cos^m \theta \cos \phi
\]

where \( P_r \) is the received luminous flux of the PD; \( P_t \) is the transmitted power of the LED; \( s \) is the effective receiving area of the PD; \( m \) is a constant parameter related to the LED. Considering the thermal noise and the shot noise [7], the actually received signal power \( \hat{P}_r \) is

\[
\hat{P}_r = P_r + n
\]

where the noise \( n \) is expressed in the form of luminance flux. The received optical power would be further converted into the electrical current by the PD, and the converted current signal with noise \( \hat{\mu} \) is

\[
\hat{\mu} = \frac{R_e}{s} (P_r + n) = \mu + \mu^n
\]

where \( R_e \) is the conversion efficiency of the PD; \( \mu = \frac{R_e}{s} P_r \); \( \mu^n = \frac{R_e}{s} n \) is the noise of current. Referring to the minimum mean square error (MMSE)-fit noise model of [8], the variance of \( \mu^n \) is expressed as

\[
(\sigma_{\mu^n})^2 = 8.0185 \times 10^{-18} + 1.869 \times 10^{-11} \mu
\]

where \( (\sigma_{\mu^n})^2 \) is the variance of \( \mu^n \).

C. AOA Estimator and the Error Vector of the Estimated Incidence Vector

As shown in Fig. 1, the \( k \)th AOA estimator [5] consists of four specially oriented PDs, and their normalized normal vectors are denoted by \( \mathbf{v}_k,q \) (\( k = 1,2 \) \( q = 1,2,3,4 \)). Such an AOA estimator is used to estimate the incidence vector \( \mathbf{r}_k \). Considering the noise in (3), the estimated incidence vector \( \hat{\mathbf{r}}_k \) is expressed as

\[
\hat{\mathbf{r}}_k = \mathbf{r}_k + \mathbf{n}_k, \quad k = 1,2
\]

where \( \mathbf{n}_k \) is the \( 3 \times 1 \) error vector of the \( k \)th estimated incidence vector. To derive \( \mathbf{n}_k \), we need to review the process of the AOA estimation in [5] and convert it to the current form. First we could calculate the received light current \( \hat{\mu}_{k,q} \) of the \( q \)th PD in the \( k \)th AOA estimator as

\[
\hat{\mu}_{k,q} = \frac{R_e}{s} P_t \left( \frac{m + 1}{2\pi d^2_k} \right) \cos^m \theta_{k,q} \mathbf{v}_k,q \mathbf{r}_k + \mu^n_{k,q}
\]

where \( d_{k,q} \) is the distance from the beacon LED to the \( q \)th PD in the \( k \)th AOA estimator; \( \theta_{k,q} \) is the radiation angle of the \( q \)th PD in the \( k \)th AOA estimator; \( \mathbf{r}_k \) is the normalized incident vector from the \( q \)th PD of the \( k \)th AOA estimator to the beacon LED; \( \mu^n_{k,q} \) is the noise of the \( q \)th PD in the \( k \)th AOA estimator in the form of current. Since the size of the AOA estimator is small, we could assume \( d_{k,q} = d_k, \theta_{k,q} = \theta_k \) and \( \mathbf{r}_{k,q} = \mathbf{r}_k \) [5], [9], which means all the PDs in an AOA estimator share the same incidence vector. With this assumption, we could rewrite (7) as

\[
\hat{\mu}_{k,q} = \mu_{\text{max},k} \mathbf{v}_k,q \mathbf{r}_k + \mu^n_{k,q}
\]

where

\[
\mu_{\text{max},k} = \frac{R_e}{s} P_t \left( \frac{m + 1}{2\pi d^2_k} \right) \cos^m \theta_k
\]

Combining the light current expressions for the four PDs in (8), we obtain the received current vector

\[
\hat{\mathbf{\mu}}_k = \mu_{\text{max},k} \mathbf{V}_{PD} \mathbf{r}_k + \mathbf{\mu}^{\mu}_k
\]

where

\[
\mathbf{\mu}^{\mu}_k = (\hat{\mu}_{k,1},\hat{\mu}_{k,2},\hat{\mu}_{k,3},\hat{\mu}_{k,4})^T
\]

\[
\mathbf{\mu}^{\mu}_k = (\mu^n_{k,1},\mu^n_{k,2},\mu^n_{k,3},\mu^n_{k,4})^T
\]
and $V_{PD}$ is the normal vector matrix of the PDs as
\[
V_{PD} = (v_{k,1}, v_{k,2}, v_{k,3}, v_{k,4})^T.
\] Applying the least square (LS) method to (10) [5, eq. (5)], we could obtain
\[
\hat{r}_k = r_k + \frac{1}{\mu_{max,k}} (V_{PD}^T V_{PD})^{-1} V_{PD}^T n_k^e.
\] Comparing (13) with (6), $n_e$ is expressed as
\[
n_k = \frac{1}{\mu_{max,k}} (V_{PD}^T V_{PD})^{-1} V_{PD}^T n_k^e.
\] To minimize the average power of the AOA estimation error $E[|n_k|^2]$, $V_{PD}$ is optimized to [5, eq. (20)]
\[
V_{PD} = \sqrt{\frac{2}{3}} \begin{pmatrix}
\cos \frac{\pi}{2}, & \sin \frac{\pi}{2}, & \frac{1}{\sqrt{2}} \\
\cos \pi, & \sin \pi, & \frac{\sqrt{2}}{\sqrt{3}} \\
\cos \frac{3\pi}{2}, & \sin \frac{3\pi}{2}, & \frac{1}{\sqrt{2}} \\
\cos 2\pi, & \sin 2\pi, & \frac{\sqrt{2}}{\sqrt{3}}
\end{pmatrix}
\] where $V_{PD}$ is the optimal normal vector matrix when the shot noise is not considered. In this work, we adopt $V_{PD}$ as our normal vector matrix.

### III. LED LOCALIZATION ALGORITHM

The incidence vector $r_k$ is defined as
\[
r_k = \frac{t - a_k}{||t - a_k||} = \frac{t - a_k}{d_k} \quad k = 1, 2
\] where $d_k = ||t - a_k||$ is the distance from the $k$th AOA estimator to the beacon LED, while $r_k, a_k$ and $t$ are all $3 \times 1$ vectors expressed as
\[
r_k = \begin{pmatrix} r_{k,1} \\ r_{k,2} \\ r_{k,3} \end{pmatrix}, \quad a_k = \begin{pmatrix} a_{k,1} \\ a_{k,2} \\ a_{k,3} \end{pmatrix}, \quad t = \begin{pmatrix} t_1 \\ t_2 \\ t_3 \end{pmatrix}.
\] From (16), we obtain
\[
t = a_1 + d_1 r_1 = a_2 + d_2 r_2
\] which can be transformed to
\[
(r_1, r_2) \begin{pmatrix} d_1 \\ -d_2 \end{pmatrix} = a_2 - a_1.
\] With the LS method, we get
\[
\begin{pmatrix} d_1 \\ -d_2 \end{pmatrix} = (A^T A)^{-1} A^T (a_2 - a_1)
\] where
\[
A = (r_1, r_2)
\] and $A^T A$ is calculated as
\[
A^T A = \begin{pmatrix} r_{1,1}^T r_1, & r_{1,2}^T r_2 \\ r_{2,1}^T r_1, & r_{2,2}^T r_2 \end{pmatrix} = \begin{pmatrix} c_1, & c_2 \\ c_2, & c_3 \end{pmatrix}
\] where $c_1, c_2$ and $c_3$ are
\[
c_1 = r_1^T r_1, \quad c_2 = r_1^T r_2 = r_2^T r_1, \quad c_3 = r_2^T r_2
\] and the inverse matrix of $A^T A$ is obtained as
\[
(A^T A)^{-1} = \frac{1}{c_1 c_3 - c_2^2} \begin{pmatrix} c_3 & -c_2 \\ -c_2 & c_1 \end{pmatrix}.
\] The rest part of (20), i.e. $A^T (a_2 - a_1)$, is calculated as
\[
A^T (a_2 - a_1) = \begin{pmatrix} r_1^T (a_2 - a_1) \\ r_2^T (a_2 - a_1) \end{pmatrix} = \begin{pmatrix} f_1 \\ f_2 \end{pmatrix}
\] where $f_1$ and $f_2$ are
\[
f_k = r_k^T (a_2 - a_1), \quad k = 1, 2.
\] Together with (20), (24) and (25), $d_1$ and $d_2$ are expressed as
\[
\begin{pmatrix} d_1 \\ d_2 \end{pmatrix} = \begin{pmatrix} c_3 f_1 - c_2 f_2 \\ c_1 c_3 - c_2^2 \end{pmatrix}
\] We could derive the estimation of $t$ with (18) and (20) as
\[
i = a_1 + d_1 r_1 + a_2 + d_2 r_2
\] where $i$ is the estimation of $t$, $A$ is the output of the AOA estimators, and $a_1, a_2$ are the known AOA estimators’ positions.

### IV. ERROR ANALYSIS

According to (14) and (15), $n_k$ is calculated as
\[
n_k = \begin{pmatrix} n_{k,1} \\ n_{k,2} \\ n_{k,3} \end{pmatrix} = \begin{pmatrix} \sqrt{6} \mu_{max,k} \\ 0 \\ 0 \end{pmatrix} \begin{pmatrix} n_{k,1}^\mu - n_{k,2}^\mu \\ -n_{k,4}^\mu \\ n_{k,3}^\mu - n_{k,2}^\mu \end{pmatrix}.
\] where $n_{k,1}^\mu, n_{k,2}^\mu, n_{k,3}^\mu$ and $n_{k,4}^\mu$ are independent. We could calculate the auto-covariance matrix $C_n = E\{n_k n_k^T\}$ as
\[
C_n = \begin{pmatrix} E[n_{k,1}^2], & 0, & E[n_{k,1} n_{k,2}] \\ 0, & E[n_{k,2}^2], & E[n_{k,2} n_{k,3}] \\ E[n_{k,3} n_{k,1}], & E[n_{k,3} n_{k,2}], & E[n_{k,3}^2] \end{pmatrix}
\] Since $a_1$ and $a_2$ are fixed parameters, we should rewrite (1) as
\[
i = g(r_1, r_2).
\] According to (5) and (29), the noise $n_k$ could be assumed as a tiny disturbance to the incidence vector $r_k$. Therefore, we could apply Taylor series expansion to (31) at point $t$, where $\hat{r}_k = r_k$,
\[
i = g(r_1, r_2) + \sum_{k=1}^2 \frac{\partial g(r_1, r_2)}{\partial r_k} \bigg|_{r_k = r_k} (r_k - r_k) + \cdots
\]
\[
\approx t + \sum_{k=1}^2 \frac{\partial i}{\partial r_k} n_k.
\]
Subtracting $t$ from both sides of (32), the estimation error $\mathbf{e}_r$ is obtained as

$$\mathbf{e}_r = \mathbf{i} - \mathbf{t} \approx \sum_{k=1}^{2} \frac{\partial \mathbf{i}}{\partial \mathbf{r}_k} \mathbf{n}_k$$

(33)

where

$$\mathbf{e}_r = (e_{r,1}, e_{r,2}, e_{r,3})^T,$$  

(34)

Equation (33) reveals the relation between the estimation error $\mathbf{e}_r$ and the noise $\mathbf{n}_k$. The derivatives in (33) essentially determine how robust the LED coordinate estimator is to the additive noise. Equation (28) leads to

$$\frac{\partial \mathbf{i}}{\partial \mathbf{r}_k} = \frac{1}{2} \left( \frac{\partial \mathbf{i}}{\partial \mathbf{r}_1} + d_1 \frac{\partial \mathbf{r}_1}{\partial \mathbf{r}_k} + \frac{\partial \mathbf{r}_2}{\partial \mathbf{r}_k} + d_2 \frac{\partial \mathbf{r}_2}{\partial \mathbf{r}_k} \right)$$

$$= \frac{1}{2} \left( \frac{\partial \mathbf{r}_1}{\partial \mathbf{r}_k} + d_1 \frac{\partial \mathbf{r}_1}{\partial \mathbf{r}_k} + d_2 \frac{\partial \mathbf{r}_2}{\partial \mathbf{r}_k} \right)$$

(35)

where $\mathbf{I}_3$ is the $3 \times 3$ identity matrix. From (27), we could calculate $\partial \mathbf{r}_1$ and $\partial \mathbf{r}_2$ as

$$\frac{\partial \mathbf{r}_1}{\partial \mathbf{r}_1} = - \frac{c_3 f_1 - c_2 f_2}{(c_1 - c_3)} \left( 2c_3 \mathbf{r}_2^T - 2c_2 \mathbf{r}_1^T \right)$$

$$+ \frac{1}{c_1 c_3 - c_2^2} \left[ c_2 (a_2 - a_1)^T - f_2 \mathbf{r}_2^T \right]$$

(36)

Similarly, $\frac{\partial \mathbf{r}_1}{\partial \mathbf{r}_2}$ and $\frac{\partial \mathbf{r}_2}{\partial \mathbf{r}_2}$ are calculated as

$$\frac{\partial \mathbf{r}_1}{\partial \mathbf{r}_2} = - \frac{c_3 f_1 - c_2 f_2}{(c_1 - c_3)} \left( 2c_1 \mathbf{r}_2^T - 2c_2 \mathbf{r}_1^T \right)$$

$$+ \frac{1}{c_1 c_3 - c_2^2} \left[ 2f_1 \mathbf{r}_2^T - c_2 (a_2 - a_1)^T - f_2 \mathbf{r}_2^T \right]$$

(37)

By substituting (36) and (37) into (35), we could derive $\frac{\partial \mathbf{i}}{\partial \mathbf{r}_1}$ and $\frac{\partial \mathbf{i}}{\partial \mathbf{r}_2}$. With (29), (35), (36) and (37), we could calculate (33) and achieve the auto-covariance matrix of $\mathbf{e}_r$ as

$$E\{\mathbf{e}_r \mathbf{e}_r^T\} \approx E\left\{ \left( \frac{\partial \mathbf{i}}{\partial \mathbf{r}_1} \mathbf{n}_1 + \frac{\partial \mathbf{i}}{\partial \mathbf{r}_2} \mathbf{n}_2 \right) \left( \frac{\partial \mathbf{i}}{\partial \mathbf{r}_1} \mathbf{n}_1 + \frac{\partial \mathbf{i}}{\partial \mathbf{r}_2} \mathbf{n}_2 \right)^T \right\}$$

$$= \frac{\partial \mathbf{i}}{\partial \mathbf{r}_1} \mathbf{C}_n \left( \frac{\partial \mathbf{i}}{\partial \mathbf{r}_1} \right)^T + \frac{\partial \mathbf{i}}{\partial \mathbf{r}_2} \mathbf{C}_n \left( \frac{\partial \mathbf{i}}{\partial \mathbf{r}_2} \right)^T.$$  

(38)

Therefore, the theoretical LED positioning error $e_{ps}$ could be denoted by

$$e_{ps} = \sqrt{E[e_{r,1}^2] + E[e_{r,2}^2] + E[e_{r,3}^2]} = \sqrt{\text{tr}(E\{\mathbf{e}_r \mathbf{e}_r^T\})}$$

$$\approx \sqrt{\text{tr} \left( \frac{\partial \mathbf{i}}{\partial \mathbf{r}_1} \mathbf{C}_n \left( \frac{\partial \mathbf{i}}{\partial \mathbf{r}_1} \right)^T + \frac{\partial \mathbf{i}}{\partial \mathbf{r}_2} \mathbf{C}_n \left( \frac{\partial \mathbf{i}}{\partial \mathbf{r}_2} \right)^T \right)}$$

(39)

where $\text{tr}(\cdot)$ denotes the trace of a matrix. Equation (39) is a novel and important equation that relate the noise statistics to the LED localization error at a certain point. With this new analytical tool, we could avoid resorting to time-consuming Monte Carlo simulations and evaluate the system error effectively.

V. SIMULATION RESULT

We use the estimated incidence vector $\hat{\mathbf{i}}$ in (6) as the input of the LED localization algorithm in (28). To test the proposed system, a room of $4 \times 4 \times 4$ m$^3$ is constructed, with a beacon LED on the ceiling and two AOA estimators on the ground. In other words, the $z$-coordinates of the beacon LED and the AOA estimators are 4 m and 0 m, respectively. Each AOA estimator has four differently oriented PDs. The transmit power $P_t = 5000$ lm, the effective receiving area of each PD $s = 15$ mm$^2$, the conversion efficiency $R_p = 22$ nA/lux, and the constant $m = 1$.

![Fig. 3.](image-url)

(a) Theoretical calculations of $e_{ps}$.

(b) Simulation results of $e_{ps}$.

In this section, we would investigate whether the result in (39) agrees with the simulation results from the Monte Carlo simulations.
Theoretical calculations of $\varepsilon_p$. Simulation results of $\varepsilon_p$.

In summary, we should be cautious about the placement of the AOA estimators. Referring to the $\varepsilon_p$ in (39), the two AOA estimators should not be set too close to each other.

VI. CONCLUSION

In this paper, a beacon LED localization system is proposed to reduce the uncertainty of the LED positions. Two AOA estimators are exploited to estimate the incidence vectors from the AOA estimators to the LED. With the incidence vectors and the positions of the AOA estimators, the proposed system could localize the LEDs. To evaluate the estimation error of the system, we derive a closed-form error expression in terms of both thermal noise and shot noise. Based on the analytical error results, the placement of the AOA estimators could affect the error greatly, and a reasonable advice for the placement is that the two AOA estimators should not be set too close to each other. With this proposed system, we have a new approach to build beacon LED coordinates databases without laborious measurements, and the mathematical tool quantifies the localization error and provides insights into the indoor optical positioning system design.
