Abstract
In the context of the Anderson model, Minami proved a Wegner type bound on the expectation of $2 \times 2$ determinant of Green’s functions. We generalize it so as to allow for a magnetic field, as well as to determinants of higher order.

1 Introduction
Minami [2] considered the Anderson model

$$ H = -\Delta + V $$

acting on $\ell^2(\mathbb{Z}^d)$, where $\Delta$ is the discrete Laplacian and $V = \{V_x\}_{x \in \mathbb{Z}^d}$ consists of independent, identically distributed real random variables, whose common density $\rho$ is bounded. He showed that in the localization regime the eigenvalues of the Hamiltonian restricted to a finite box $\Lambda \subset \mathbb{Z}^d$ are Poisson distributed if appropriately rescaled in the limit as $\Lambda$ grows large. The result and, up to small changes, its proof also apply when the kinetic energy $-\Delta$ is replaced by a more general operator $K = K^*$ with a rapid off-diagonal decay of its matrix elements $K(x, y)$ in the position basis $(x, y \in \mathbb{Z}^d)$, as long as

$$ K(x, y) = K(y, x). $$

Use of this property is made in the proof of Lemma 2 in [2], where $H$, and hence its resolvent $G(z) = (H - z)^{-1}$, is assumed symmetric: $G(z; x, y) = G(z; y, x)$, cf. eqs. (2.68, 2.75).

In physical terms, eq. (1) corresponds to the absence of an external magnetic field, and it may thus be desirable to dispense with it. This is achieved in this note. But first we recall Minami’s Lemma 2. Let $\text{Im} \, G = (G - G^*)/2i$. Then [2]

$$ \mathbb{E} \left[ \det \begin{pmatrix} (\text{Im} \, G)(z; x, x) & (\text{Im} \, G)(z; x, y) \\ (\text{Im} \, G)(z; y, x) & (\text{Im} \, G)(z; y, y) \end{pmatrix} \right] \leq \pi^2 \|\rho\|_{\infty}^2, $$

(2)
for \( x \neq y \) and \( \text{Im} \, z > 0 \), and similarly if the Hamiltonian \( H \) is truncated to a subset \( \Lambda \subset \mathbb{Z}^d \) with \( x, y \in \Lambda \).

Because of \( G^*(z; x, y) = \overline{G(z; y, x)} \), the above matrix element

\[
(\text{Im} \, G)(z; x, y) = \frac{G(z; x, y) - \overline{G(z; y, x)}}{2i}
\]

agrees with \( \text{Im}(G(z; x, y)) \) only if the symmetry (1) is assumed, which we shall not do here. Then the agreement is limited to \( x = y \). For the sake of clarity we remark that it is the operator interpretation (3) of \( \text{Im} \, G \), and not the one in the sense of matrix elements, which makes (2) true and useful in the general case.

The core of the argument is contained in the following

**Lemma 1** Let \( A = (a_{ij})_{i,j=1,2} \) with \( \text{Im} \, A > 0 \). Then

\[
\int dv_1 dv_2 \det \left( \text{Im}[\text{diag}(v_1, v_2) - A]^{-1} \right) = \frac{\det \text{Im} A}{\sqrt{(\det \text{Im} A)^2 + \frac{1}{2}(\det \text{Im} A)(|a_{12}|^2 + |a_{21}|^2) + \frac{1}{16}(|a_{12}|^2 - |a_{21}|^2)^2}}. \tag{4}
\]

The right hand side is trivially bounded by \( \pi^2 \), since \( \det \text{Im} A > 0 \). In [2], eqs. (2.72, 2.74), the equality was established in the special case \( a_{12} = a_{21} \). It was applied to

\[
-(A^{-1})(u, v) := (\hat{H} - z)^{-1}(u, v), \quad (u, v = x, y),
\]

where \( \hat{H} \) is \( H \) with \( V_x \) and \( V_y \) set equal to zero. With the so defined \( 2 \times 2 \) matrix \( A \) the two matrices under "det Im" in [2] and on the left hand side of (4) agree, a fact known as Krein’s formula. That \( A \) is actually well-defined and satisfies \( \text{Im} \, A > 0 \) is seen from \( \text{Im}(z - \hat{H}) = \text{Im} \, z > 0 \) and the following remarks [3], which apply to any complex \( n \times n \) matrix \( C \):

(i)

\[
\text{Im} \, C > 0 \iff \text{Im}(-C^{-1}) > 0.
\]

Indeed, \( C \) is invertible, since otherwise \( Cu = 0 \) for some \( u \neq 0 \in \mathbb{C}^n \), implying \( (u, (\text{Im} \, C)u) = \text{Im}(u, Cu) = 0 \), contrary to our assumption. Moreover, \( \text{Im}(-C^{-1}) = C^{-1*}(\text{Im} \, C)C^{-1} \). The converse implication is because \( C \mapsto (-C)^{-1} \) is an involution.

(ii)

\[
\text{Im} \, C > 0 \implies \text{Im} \, \hat{C} > 0,
\]

where \( \hat{C} \) is the restriction of \( C \) to a subspace, as a sesquilinear form. In fact, \( \text{Im} \, \hat{C} = \text{Im} \, C \).

A more qualitative understanding of the bound \( \pi^2 \) for (4) may be obtained from its generalization to \( n \times n \) matrices:

**Lemma 2** Let \( A = (a_{ij})_{i,j=1,\ldots,n} \) with \( \text{Im} \, A > 0 \). Then

\[
\int dv_1 \cdots dv_n \det \left( \text{Im}[\text{diag}(v_1, \ldots, v_n) - A]^{-1} \right) \leq \pi^n.
\]

As a result, eq. (2) also generalizes to the corresponding determinant of order \( n \).
2 Proofs

Proof of Lemma 1. Following [2] we will use that
\[ \int dx \frac{1}{|ax + b|^2} = \frac{\pi}{\text{Im}(ba)} \quad , \quad (a, b \in \mathbb{C}, \text{Im}(ba) > 0) \quad (7) \]
and
\[ \int dx \frac{1}{ax^2 + bx + c} = 2\pi \frac{\sqrt{\Delta}}{\sqrt{\Delta}}, \quad (a > 0, b, c \in \mathbb{R}, \Delta := 4ac - b^2 > 0). \quad (8) \]
We observe that
\[ \det \text{Im} A = (\text{Im} a_{11})(\text{Im} a_{22}) - \frac{1}{4}|a_{12} - \overline{a_{21}}|^2, \quad (9) \]
and hence the right hand side of (11), do not depend on Re\( a_{ii} \), (\( i = 1, 2 \)). Similarly the left hand side, by a shift of integration variables. We may thus assume Re\( a_{ii} = 0 \). The matrix on the left hand side of (11) is
\[ \text{Im}(\text{diag}(v_1, v_2) - A)^{-1} = (A^* - \text{diag}(v_1, v_2))^{-1} (\text{Im} A)(A - \text{diag}(v_1, v_2))^{-1}, \quad (10) \]
and its determinant equals
\[ \det \text{Im} A \cdot |\det(A - \text{diag}(v_1, v_2))|^{-2} = \det \text{Im} A \cdot |(v_1 - a_{11})(v_2 - a_{22}) - a_{12}a_{21}|^{-2}. \quad (11) \]
The \( v_2 \)-integration of the second factor (11) is of the type (7) with \( a = v_1 - a_{11} \) and \( b = (a_{11} - v_1)a_{22} - a_{12}a_{21} \). Then
\[ \text{Im}(ba) = (\text{Im} a_{22})|v_1 - a_{11}|^2 + \text{Im}(a_{12}a_{21})(v_1 - \text{Re} a_{11}) + \text{Re}(a_{12}a_{21})(\text{Im} a_{11}) \]
\[ = (\text{Im} a_{22})v_1^2 + \text{Im}(a_{12}a_{21})v_1 + (\text{Im} a_{22})(\text{Im} a_{11})^2 + \text{Re}(a_{12}a_{21})(\text{Im} a_{11}). \quad (12) \]
By (8), the \( v_1 \)-integral is obtained by computing the discriminant \( \Delta \) of this quadratic function:
\[ \int dv_1dv_2 |\det(A - \text{diag}(v_1, v_2))|^{-2} = \frac{2\pi^2}{\sqrt{\Delta}}, \quad (13) \]
\[ \Delta = 4(\text{Im} a_{11} \text{Im} a_{22})^2 + 4(\text{Im} a_{11} \text{Im} a_{22}) \text{Re}(a_{12}a_{21}) - (\text{Im} a_{12}a_{21})^2 \]
\[ = (2 \text{Im} a_{11} \text{Im} a_{22} + \text{Re}(a_{12}a_{21}))^2 - |a_{12}a_{21}|^2. \]

In doing so we tacitly assumed that \( \Delta \), and hence (12), are positive. This is indeed so, because \( \Delta \leq 0 \) would imply that \( A - \text{diag}(v_1, v_2) \) is singular for some \( v_1, v_2 \in \mathbb{R} \), which contradicts \( \text{Im} A > 0 \), cf. (5). It also follows because \( \Delta/4 \) equals the expression under the root in (4), a claim we need to show anyhow: from (2) and
\[ |a_{12} - \overline{a_{21}}|^2 = |a_{12}|^2 + |a_{21}|^2 - 2 \text{Re}(a_{12}a_{21}) \]
we obtain
\[ 2 \text{Im} a_{11} \text{Im} a_{22} + \text{Re}(a_{12}a_{21}) = 2 \text{det} \text{Im} A + \frac{1}{2}(|a_{12}|^2 + |a_{21}|^2) \]

3
and hence
\[ \Delta = 4(\det \text{Im} A)^2 + 2(|a_{12}|^2 + |a_{21}|^2)(\det \text{Im} A) + \frac{1}{4}(|a_{12}|^2 + |a_{21}|^2)^2 - |a_{12}a_{21}|^2. \]

Since the last two terms equal \((|a_{12}|^2 - |a_{21}|^2)^2/4\), we establish the claim and, by eqs. \(^{11}\) \(^{13}\), the lemma.

**Proof of Lemma 2.** By induction in \(n\). It may start with \(n = 0\), in which case the determinant is 1 by natural convention, or with \(n = 1\), where the claim, i.e.,
\[ \int dv \text{ Im}\left( \frac{1}{v - a} \right) \leq \pi, \quad (\text{Im} a > 0), \]
is easily seen to hold as an equality. We maintain the induction step
\[ \int dv_n \det(\text{Im}[\text{diag}(v_1, \ldots, v_n) - A]^{-1}) \leq \pi \det(\text{Im}[\text{diag}(v_1, \ldots, v_{n-1}) - B]^{-1}) \]
for some \((n - 1) \times (n - 1)\) matrix \(B\) with \(\text{Im} B > 0\). This is actually a special case of
\[ \int dv \det(\text{Im}[\text{diag}(0, \ldots, 0, v) - A]^{-1}) \leq \pi \det(-B)^{-1}, \tag{14} \]
where \(B\) is the Schur complement of \(a_{nn}\), given as
\[ B = \tilde{A} - a_{nn}^{-1}(a_V \otimes a_H) \tag{15} \]
in terms of the \((n - 1, 1)\)-block decomposition of an \(n \times n\) matrix:
\[ C = \begin{pmatrix} \tilde{C} & c_V \\ c_H & c_{nn} \end{pmatrix}. \]

By a computation similar to \(^{10}\) the integrand in \(^{14}\) is
\[ \frac{\det \text{Im} A}{|\det(A - \text{diag}(0, \ldots, 0, v))|^2} = \frac{\det \text{Im} A}{|\det A - v \det \tilde{A}|^2} \]
\[ = \frac{\det \text{Im} A}{|\det A|^2 |1 - v(A^{-1})_{nn}|^2} = \frac{\det \text{Im}(-A^{-1})}{|1 - v(A^{-1})_{nn}|^2}. \]
In the first line we used that \(v \in \mathbb{R}\) and that the determinant is linear in the last row; in the second that
\[ (C^{-1})_{nn} \cdot \det C = \det \tilde{C}. \tag{16} \]
By \(^{17}\) the integral is \(\pi\) times
\[ \frac{\det \text{Im}(-A^{-1})}{\text{Im}(-A^{-1})_{nn}} = \frac{\det \text{Im}(-A^{-1})}{\text{Im}(-A^{-1})}_{nn} \leq \det[\text{Im}(\tilde{A}^{-1})] = \det \text{Im}(-\tilde{A}^{-1}), \]
where the estimate is by applying
\[ \det C \leq c_{nn} \cdot \det \tilde{C}, \quad (C > 0) \]
to $C = \text{Im}(-A^{-1})$, cf. (15). This inequality is by Cauchy’s for the sesquilinear form $C$: letting $\delta_n = (0, \ldots, 0, 1)$,

$$1 = (C^{-1} \delta_n, C \delta_n)^2 \leq (C^{-1} \delta_n, CC^{-1} \delta_n) \cdot (\delta_n, C \delta_n) = (C^{-1})_{nn} \cdot c_{nn},$$

cf. (16). Finally, $\widehat{A^{-1}}$ may be computed by means of the Schur (or Feshbach) formula [1]: $A^{-1} = B^{-1}$ with $B$ as in (15). Note that the left hand side is invertible because of $\text{Im}(-\widehat{A^{-1}}) > 0$, cf. (5, 6), and that it is the inverse of a matrix with positive imaginary part. □
