Butyrate has been reported to promote the performance and growth of chickens. The specific roles and efficacy of different sources of butyrate remained unclear. Thus, the present study aimed to investigate and compare the effects of Clostridium butyricum (CB), sodium butyrate (SB), and butyric acid glycerides (tributyrin, BAG) on the reproductive performance, egg quality, intestinal health, and offspring performance of yellow-feathered breeder hens. A total of 300 Lingnan yellow-feathered breeder hens were assigned to five treatment groups: control (CL), 1 × 10^8 CFU/kg CB (CBL), 1 × 10^9 CFU/kg CB (CBH), 500 mg/kg SB, and 300 mg/kg BAG. Results showed that the laying performance and egg quality were increased by CBL, CBH, and BAG. Both CB treatments increased the hatchability of fertilized eggs. Maternal supplementation with both levels of CB significantly elevated the growth performance of offspring. Treatment with CBL, CBH, SB, and BAG all improved the oviduct-related variables and reduced the plasmal antioxidant variables. The CBH, CBL, and BAG treatments also improved the intestinal morphology to different degrees. Jejunal contents of IL-6 were decreased by CBH and BAG, while those of IL-4, IL-6, IL-1β, and IgY were decreased by SB. Transcripts of nutrient transporters in jejunal mucosa were also upregulated by CBH, CBL, and SB treatments and expression of Bcl-2-associated X protein was decreased by CBL, CBH, and BAG. In cecal contents, CBL increased the abundance of Firmicutes and Bacillus, while CBH decreased the abundance of Proteobacteria. Also, the co-occurrence networks of intestinal microbes were regulated by CBH and BAG. In conclusion, dietary inclusion of CB and BAG improved the reproductive parameters, egg quality, and intestinal morphology of breeders. CB also influenced the hatching performance of breeders and growth performance of the offspring, while SB improved the oviduct-related variables. These beneficial effects may result from the regulation of cytokines, nutrient transporters, apoptosis, and gut microbiota; high-level
CB had more obvious impact. Further study is needed to explore and understand the correlation between the altered gut microbiota induced by butyrate and the performance, egg quality, intestinal health, and also offspring performance.

Keywords: reproductive performance, Clostridium butyricum, sodium butyrate, butyric acid glycerides, yellow-feathered breeder hens

INTRODUCTION

Butyrate, a short-chain fatty acid (SCFA), is a main end-product of intestinal microbial fermentation of dietary fiber (Xiao et al., 2020). Butyrate is important for the health of animals because it provides nutrition for epithelial cells and helps inhibit pathogens in the gut (Meimandipour et al., 2010).

Clostridium butyricum (CB) is a butyric acid-producing Gram-positive anaerobe and has been used as a feed additive in poultry industry. Previous studies in chickens suggested that CB promoted growth performance (Zhang et al., 2011; Yang et al., 2012), improved intestinal morphology (Zhang et al., 2011), altered intestinal microbiota (Meimandipour et al., 2010; Yang et al., 2012), and ameliorated inflammation (Zhang et al., 2016; Takahashi et al., 2018). Similarly, sodium butyrate (SB), functioning as butyric acid in the acidic environment of the proximal digestive tract of the birds (Ahsan et al., 2016), also increased the growth performance (Sikanadar et al., 2017), meat quality (Deepa et al., 2017; Gomathi et al., 2018), and anti-inflammatory ability of chickens (Jiang et al., 2015). Butyric acid glycerides (BAG), the tributyl ester compound, is an enriched source with fewer undesirable properties. Previous research indicated that BAG effectively improved the growth performance and lipid metabolism of broilers (Taherpour et al., 2009). In the study of Jahanian and Golshadi (2015), the productive performance of laying hens was found to be enhanced by BAG.

Although CB, SB, and BAG promoted the performance and growth of breeder hens, their specific roles and efficacy remained unclear. The present study, therefore, was designed to investigate and compare the effects of CB, SB, and BAG on the reproductive performance, egg quality, intestinal health, and offspring performance of yellow-feathered breeder hens, breeds of major importance in China. In addition, because of apparent altered function of the small intestine, the relative expression of selected nutrient transporter genes, and other relevant transcripts, was measured.

MATERIALS AND METHODS

Breeder Hens and Management

The experimental protocol was approved by the Animal Care Committee of the Institute of Animal Science, Guangdong Academy of Agriculture Science, Guangzhou, China, with the approval number GAASISA-2019-007. A total of 300 Lingnan yellow-feathered breeder hens of 45 weeks of age with similar BW (3.02 ± 0.01 kg) and laying rate were used.

Breeder hens were randomly allocated into five treatment groups, each with 10 replicates of 6 birds. The trial lasted from 45 to 54 weeks of age. During the experimental period, hens were housed singly in laying cages, received 120 g of feed per bird per day to prevent over-feeding, and had access to fresh water ad libitum. Breeder hens received artificial insemination of 25 μl pooled semen per bird every 3 days. Twenty males were used and received the basal diet. At the end of the experiment, eggs were collected and incubated as described below.

One hundred hatched chicks, pooled from each treatment, were divided into five replicates and fed a standard diet for 28 days in pens (stocking density 0.38 m²/bird). Daylight was eliminated and replaced with 18-h lighting from incandescent bulbs. The temperature of the room was maintained at 32 to 34°C for the first 3 days and then reduced by 2 to 3°C per week to a final temperature of 26°C. Chicks received feed and fresh water ad libitum.

Diets

All breeder hens were fed the same basal diet (Supplementary Table S1) to which 1 × 10⁸ CFU/kg Clostridium butyricum (CBL), 1 × 10⁸ CFU/kg Clostridium butyricum (CBH), 500 mg/kg coated sodium butyrate (SB), and 300 mg/kg BAG were added to obtain the treatments. Clostridium butyricum (1 × 10⁸ CFU/kg) and coated sodium butyrate (effective content: 40% butyrate) were purchased from Hujiia Biological Technology Co., Ltd. (Hangzhou, China). BAG (tributyrin: 45% butyrate) was obtained from Youjiu Biological Technology Co., Ltd. (Shanghai, China). All offspring chicks were fed a common diet (Supplementary Table S2).

Production Performance and Egg Quality

Egg production, egg weight, and number of qualified eggs were recorded daily. The unqualified eggs included misshapen eggs, dirty eggs, excessively large or small eggs, broken eggs, cracked eggs, and eggs without a shell (but with intact membrane) according to Duan et al. (2015). The laying rate, daily egg mass, average egg weight, and qualified rate of egg were calculated. At 53 weeks of age, three eggs per replicate were selected to determine the egg quality, including egg shape index, yolk ratio, yolk color, albumen height, Haugh unit (automatic egg analyzer, EM-5200 Robotmation Co., Ltd., Tokyo, Japan), eggshell thickness (by micrometer), and eggshell strength (eggshell strength tester, FGV-10XY, Orka Food Technology, Ramat HaSharon, Israel).

At 55 weeks of age, 30 eggs from each replicate and 10 replicates from each treatment were selected for hatching.
All eggs were incubated in the same incubator (Bengbu Sanyuan Incubation Equipment Co., Ltd., Anhui, China) at 37.2°C to 38.0°C and 60 to 75% relative humidity. Eggs were turned 12 times/day throughout the incubation period and sprayed with water once daily from the 15th day of incubation until they hatched (Xia et al., 2020). The fertility, hatch of fertile eggs and hatching weight were recorded and calculated.

At the end of the experiment, one hen from each replicate was selected to measure the weight and length of the oviduct, the weight of ovarian stroma, the number and weight of large yellow follicles (LYF), and the number and weight of small yellow follicles (SYF). The oviduct included the funnel part, enlargement, isthmus, and the uterus. The LYF (>8 mm) and SYF (3–8 mm) were identified by measuring the diameter using the vernier caliper.

The growth performance of the 20 offspring from each replicate was also determined. The average daily gain (ADG) was determined from BW at hatching and day 28. The average daily feed intake was determined from feed consumed by each replicate.

### Biochemical Determinations

At the end of the experiment, hens selected at Section “Production Performance and Egg Quality” were weighed and 6 ml heparinized blood was obtained via the wing vein. Plasma was obtained by centrifugation at 1,500 x g for 10 min. The birds were then killed by cervical dislocation. Liver, ovary and jejunal mucosa (rinsed and scraped with a glass slide) were collected and snap-frozen in liquid N₂, homogenized with ice-cold physiologic saline (1:10, v/v), and centrifuged at 2,000 x g for 10 min. The activities of alkaline phosphatase (AKP), total antioxidant capacity (T-AOC), diamine oxidase (DAO), total superoxidase dismutase (T-SOD), and content of uric acid in the plasma and in the supernatants of liver, jejunal mucosa, and ovary were analyzed spectrophotometrically using commercial kits (Nanjing Jiancheng Bioengineering Institute, Nanjing, China).

### Intestinal pH and Morphology

The pH of small intestinal contents was measured with a portable meter equipped with an insertion glass electrode (HI8424, HANA Instrument Science and Technology Co., Ltd., Beijing, China). Duodenum, jejunum, and ileum were collected immediately after slaughter. The intestines were opened with sterile scissors, and pH of the contents was measured by inserting a glass pH electrode probe.

One-centimeter lengths from the medial portions of the jejunum were washed in physiological saline solution and fixed in 10% buffered formalin. Tissue samples were later embedded in paraffin, and a 20-μm sections of each sample were dewaxed, mounted on glass slides, and stained with hematoxylin and eosin. Slides were blindly evaluated microscopically (Eclipse Ti-E, Nikon, Japan). Villus height was measured from the top of the villus to the junction of villus and crypt, and crypt depth was measured as the depth of the invagination between adjacent villi using scanning browsing software (CaseViewer2.2, 3DHISTECH, Hungary) and scanning analysis software (Halo v3.0.311.314, Indica Labs, Albuquerque, NM). For each jejunal sample, the height of five intact villi and the corresponding depths of five crypts were measured and the average value was calculated.

### RT-qPCR

Total RNA extraction from the mucosa of jejunum was performed using TRIzol reagent (RNAiso plus 9109, Takara, Tokyo, Japan) and reverse-transcribed with PrimeScript II 1st Strand cDNA Synthesis Kit (6210A, Takara). Real-time PCR was performed with SYBR PremixExTaq II (Takara) and an ABI 7500 real-time PCR system (Applied Biosystems, Carlsbad, CA), as described by Satoh et al. (2010). The primers used are provided in Supplementary Table S3. Results were normalized to the abundance of β-actin transcripts, and relative quantification was calculated using the 2-ΔΔCt method.

### Immune Variables

Jejunal mucosal samples were homogenized with ice-cold physiologic saline (1:10, v/v) and centrifuged at 2,000 x g for 10 min (Centrifuge 5804R, Eppendorf, Germany). Supernatants were collected, and ELISAs were performed to determine the levels of IL-4, IL-6, IL-1β, TNF-α, IgM, IgA, and IgY using kits (Bio-function Technology Co., Ltd., Beijing, China).

### Microbial Analysis

Bacterial genomic DNA was extracted from cecal contents of breeder hens using the TIANamp Stool DNA Kit (Tiangen, Beijing, China). The V3/V4 region of the 16S ribosomal RNA gene was amplified by using the 341F/805R primer pairs, and the sequencing was performed on an Illumina MiSeq platform (Illumina Inc., San Diego, CA). Raw sequences were filtered and clustered into operational taxonomic unit (OTU) at 97% similarity by QIIME 2 software. Bacterial OTU representative sequences were assigned to a taxonomic lineage by Ribosomal Database Project classifier based on the Greengenes 13.8 database. Alpha diversity was analyzed by QIIME 2 software. Beta diversity was analyzed and plotted by principal coordinates analysis (PCoA) using the “ggplot2” package of R software. Permutational multivariate analysis of variance (PERMANOVA) was calculated by “vegan” package to determine significant differences in microbial beta diversity among the treatment groups (based on the Bray-Curtis distance matrices). To determine the highly dimensional intestinal microbes and characterize the differences among the treatments, linear discriminant analysis (LDA) effect size (LEfSe) analysis was used. Co-occurrence networks of microbial communities in different treatments were built based on significant correlations (Spearman’s R > 0.6 and FDR-adjusted p < 0.05; Jiao et al., 2016) and were visualized by Gephi software (version 0.9.2). The topological properties of networks were calculated to describe the complex patterns of the interrelationships. All the DNA datasets have been submitted

2. https://huttenhower.sph.harvard.edu/galaxy/
to the NCBI Sequence Read Archive database under the BioProject ID: PRJNA695347.

Statistical Analysis
Replicate served as the experimental unit. The effects of dietary CB, SB, and BAG were analyzed by one-way ANOVA (SPSS Inc., Chicago, IL). Means were separated by Duncan's multiple range test. Tabulated results are shown as means with SEM derived from the ANOVA error mean square.

RESULTS

Laying Performance of Yellow-Feathered Breeder Hens
As shown in Table 1, supplementation with high or low-level CB and BAG increased the laying rate ($p < 0.05$). CBH and BAG also increased the daily egg mass ($p < 0.05$). The feed:egg ratio was decreased by the high and low level of CB and BAG ($p < 0.05$).

Hatching Performance and Egg Quality of Yellow-Feathered Breeder Hens
According to Table 2, CBL, CBH, SB, and BAG had no significant effects on the fertility, hatch of fertile eggs, and hatching weight, compared to the controls (CL). Birds in the CBL treatment had lower hatchability of fertilized eggs ($p < 0.05$) than those receiving CBH. Significantly, increased ($p < 0.05$) albumen height and eggshell thickness were noted for the CBH treatment and CBL increased the albumen height ($p < 0.05$; Table 3). The BAG treatment increased ($p < 0.05$) the yolk color and Haugh unit.

Oviduct-Related Variables of Yellow-Feathered Breeder Hens
Compared with the controls, CBH treatment increased ($p < 0.05$) the weight and length of the oviduct, and number and weight of LYF. Number and weight of LYF also increased ($p < 0.05$) by CBL, SB increased weight of the oviduct, and number and weight of LYF, while BAG treatment increased ($p < 0.05$) the number of LYF (Table 4).

Biochemical Variables of Yellow-Feathered Breeder Hens
Treatments with CBH, CBL, and SB all decreased ($p < 0.05$) T-AOC activity and uric acid concentration, CBH also lowered plasmal T-SOD activity ($p < 0.05$), and BAG treatment significantly decreased T-AOC and T-SOD activity (Table 5). There were no effects of treatment on the activities of T-AOC and T-SOD in jejunal mucosa, liver, or ovary (Table 6).

Intestinal Morphology of Yellow-Feathered Breeder Hens
The pH of duodenal, jejunal, and ileal digesta was not significantly influenced by treatment ($p > 0.05$). Jejunal morphology was improved by CBH, CBL, and BAG. As shown in Table 6,

TABLE 1 | Laying performance of yellow-feathered breeder hens.
| CL | CBH | CBL | SB | BAG | SEM | Value of $p$ |

$^a$Means within a row lacking a common superscript differ significantly ($p < 0.05$). CL, control; CBL, low-level Clostridium butyricum; CBH, high-level Clostridium butyricum; SB, sodium butyrate; BAG, butyric acid glycerides; and SEM, standard error.

CBH increased ($p < 0.05$) the villus height, crypt depth, and the villuscrypt ratio, CBL increased ($p < 0.05$) the villus height and villuscrypt ratio, and BAG increased ($p < 0.05$) the villus height and crypt depth of jejunal mucosa.

Immune Factors of Yellow-Feathered Breeder Hens
The contents of cytokines and immunoglobulins in the jejunal mucosa were determined (Table 7). The only effect on IL-4 was the reduction ($p < 0.05$) caused by SB treatment. Contents of IL-6 were reduced ($p < 0.05$) by CBH, SB, and BAG. The SB treatment also reduced IL-1$\beta$ and IgY, the latter quite strikingly, and SB also resulted in lowest contents of IgA.

Jejunal Gene Expression of Yellow-Feathered Breeder Hens
The relative transcript abundance of Na$^+$/H$^+$ exchanger isoform 2 (NHE2) was increased ($p < 0.05$) by CBL and SB, that of peptide transporter 1 (PEPT1) by CBL and SB, glucose transporter-2 (GLUT2) by both CBH and CBL, and apical nutrient transporter SLC6A19 ($^{B^y}$AT) was increased only by CBH. The apoptosis-related gene Bcl-2-associated X protein (BAX) was downregulated ($p < 0.05$) by CBH, CBL, and BAG; the expression of $^{T^N}$F-$\alpha$ was not significantly affected by treatment (Table 8).

Gut Microbiota Structure of Yellow-Feathered Breeder Hens
The results showed that the CBL treatment decreased the variables of the observed species, Chao1, Shannon and Simpson

BW, body weight; LYF, large yellow follicles, follicles with mean diameter >8 mm; SYF, small yellow follicles, follicles with mean diameter of 3 to 8 mm. CL, control; CBL, low-level Clostridium butyricum; CBH, high-level Clostridium butyricum; SB, sodium butyrate; BAG, butyric acid glycerides; and SEM, standard error.

(p < 0.05) compared to the controls (Figure 1). PCoA of intestinal microbiota based on Bray-Curtis distance revealed distinct clusterings of the gut microbiota composition between CL and CBH, and between CL and BAG (Figure 2). The differences in the intestinal bacterial compositions between the treatments were also analyzed. The results showed that at the phylum level, CBH and CBL treatments obviously increased the abundance of Firmicutes. Additionally, CBH also decreased the abundance of Proteobacteria. At the family level, CBL increased (p < 0.05) the abundance of Bacillaceae over those of the CL and BAG treatments. At the genus level, no significant treatment differences were noticed in the abundance of Clostridium (Figure 3).

In order to further identify microbial taxa that account for the greatest differences between genders, we performed LDA coupled with effect size measurements (LEfSe). In the total cohort, families with higher abundance in the CL controls included Methanobrevibacter and Ruminiclostridium5. The genus Shuttleworthia was higher in the CBH treatment. Bacillales, Bacteroides, Bacillus and Lactobacillaceae, Lactobacillales, and Lactobacillus were more abundant in the CBL treatment. The SB treatment induced higher abundances of Barnesiellaceae, ClostridialesvadinBB60, Defluvitaleaceae, Angelakisella, Ruminococcaceae, and Mitochondria. Moreover, more abundant Bacteroidales, Bacteroidaceae, Bacterides, and Bacteroides were observed in BAG treatment (Figure 4).

To investigate the co-occurrence patterns of intestinal microbes in the groups, three networks were constructed based on the OTU level (Figure 5 and Table 9). Co-occurrence network analysis showed that the microbial networks were roughly at the same edges and nodes among the different treatments. The values of average degree (AD) in breeder hens treated with CBH and BAG were higher than those in the controls; the graph density (GD) and the modularity (MD) values were not altered obviously among groups. Additionally, the negative correlations of the network in the CBH and BAG treatments were more than that of the controls while the positive correlations of the network were less than that of the controls.

**Growth Performance of Offspring Broilers**

Compared to the control breeders, CBH breeders produced offspring with increases (p < 0.05) in the final BW and ADG, and with decreased (p < 0.05) feed:gain. The feed:gain of offspring from the CBL treatment was also decreased (p < 0.05; Table 10).

**DISCUSSION**

Evidence exists for butyric acid exerting beneficial effects on the laying and hatching performances of hens (Jahanian and Golshadi, 2015; Zhan et al., 2019). In accordance with these findings, in the current study, CB and BAG were also found to increase the laying rate as well as daily egg weight, while decreasing the feed:egg ratio of yellow-feathered breeder hens. Additionally, because butyrate promoted the absorption and utilization of minerals including calcium (Soltan, 2008; Casselbrant et al., 2020), egg quality might be improved by dietary addition of butyric acid. Eggshell strength (Zhan et al., 2019) and yolk color (Wang et al., 2020) were increased by dietary CB. In the present study, parameters of egg quality, such as albumen height and eggshell thickness, were also improved by CB, and yolk color and Haugh unit were elevated by BAG. It was noteworthy that the offspring broilers from breeders fed the CBH diet had a much better growth performance than that in other treatments.

The hen oviduct was of special interest to commercial egg producers because disrupted activity or pathological changes

Frontiers in Microbiology | www.frontiersin.org 5 September 2021 | Volume 12 | Article 657542
directly affected egg quality and ultimately decreased economic profitability (Chousalkar and Roberts, 2008). In the present study, the oviduct-related variables, such as weight of the oviduct, and number and weight of LYF, were improved by the treatment of CB, SB, or BAG. Little was known about the effects of butyrate on oviduct-related variables to serve for comparison with the present results. However, according to Ghosh and Cox (1977), SB induced the secretion of follicle-stimulating hormone (FSH), which stimulated the growth and development of follicles. Thus, butyrate might promote the reproductive ability and egg quality through regulating oviduct development by inducing FSH secretion.

It is reported that oxidative stress decreased the hatchability and increased the mortality post-hatch (Nadia et al., 2008). Thus, the elevated hatchability and reproductive performance in the present study prompted us to investigate the oxidative status of breeder hens among the different treatments. It was reported that dietary provision of CB promoted the serum, hepatic, and intestinal antioxidant status of hosts (Liao et al., 2015; Duan et al., 2017; Zhan et al., 2019) and SB also improved antioxidant capacity in vitro and in vivo (Xing et al., 2016; Honma et al., 2020). It was found here, however, that CB, SB, and BAG had minimal effect on the activities of T-SOD and T-AOC in jejunal mucosa, liver, and ovary; SB did reduce jejunal T-SOD activity. Plasmal activity of T-AOC was decreased by CB, SB, and BAG treatments, and activity of T-SOD was reduced by BAG and CBH. As the performance of yellow-feathered breeder hens in the current study was significantly improved, the decreased antioxidant variables might be due to the decreased expression of reactive oxygen species-generating proteins, rather than the impairment of the antioxidant system. The plasmal content of uric acid was also reduced by treatment with CBH, CBL, and SB. Uric acid was the major final product of nitrogen metabolism in birds and was an endogenous antioxidant (Sauer et al., 2007). In the study of Al-Yasiry et al. (2017), dietary supplementation with Boswellia serrata resin, a putative anti-inflammatory agent, improved the performance of broiler chickens and decreased uric acid. Decreased plasmal content of uric acid might suggest greater efficiency of use of absorbed amino acids or reduced turnover of endogenous proteins in broiler chickens (Scanes, 2015; Al-Yasiry et al., 2017). Moreover, oxidative stress played a pivotal role in apoptosis and the elevation of antioxidant status could block or delay apoptosis (Kannan and Jain, 2000). It was found here that the expression of the pro-apoptosis gene BAX was downregulated by CBH, CBL, and BAG, but not by SB, suggesting that CB and BAG likely attenuated apoptosis.

Relationships were found between reproductive performance and immune function. For example, TLR4 polymorphisms offered a meaningful tool to judge the reproductive potential (Shimizu et al., 2017). The immunostimulatory property of butyrate in chickens was known (Sunkara et al., 2011). Zhou et al. (2014) discovered that SB suppressed the expression of IL-1β, IL-6, IFN-γ, and IL-10 in chicken macrophages stimulated by S. typhimurium LPS. The present study also showed that SB reduced jejunal contents of IL-4, IL-6, and IL-1β. The CBH treatment decreased jejunal content of IL-6, supporting recent work that CB administration reduced IL-6 level in the intestine of burned mice (Zhang et al., 2020). Immunoglobulins are key immune mediators. Levels of IgM and IgA in jejunal mucosa were not altered by CB, SB, or BAG, but IgY level was reduced by SB. Previous studies have suggested that SB increased IgY to improve immune function. For instance, Makled et al. (2019) found that meat-type chickens receiving a SB diet increased IgY, and Gong et al. (2020) showed that β-carotene, curcumin, allicin, and SB supplementation increased serum IgY in breeder hens. The decreased jejunal IgY of SB-treated breeder hens in the present study may indicate weakened humoral immunity. Altogether, the above findings indicated that CBH, SB, and BAG affected jejunal cytokines and SB might have an adverse effect on humoral immunity of breeder hens.

Interactions between nutrition and immunity were diverse and had profound implications on animal productivity. A supply of nutrients at the appropriate times and amounts was important for the immune system (Humphrey and Klasing, 2004). Nutrient transporters mediated substrate-specific uptake across the plasma membrane. Reports showed that SCFA enhanced the structural and functional adaptation of the mammalian intestine by increasing transcript abundance of GLUT2 (Tappenden et al., 1997; Tappenden and McBurney, 1998; Mangian and Tappenden, 2009), mediating one of the major pathways of intestinal sugar absorption (George and Edith, 2005). In the present study, both CBH and CBL increased GLUT2 transcripts in the avian jejunal mucosa. Electroneutral Na absorption in the intestine used NHE isoforms NHE2 and NHE3. Butyrate was reported to stimulate electroneutral Na absorption through NHE2 (Subramanya et al., 2007). In the current study, CBL and SB also upregulated the jejunal expression of NHE2. Protein was hydrolyzed to small peptides and amino acids in the small intestine, and dipeptides and tripeptides were transported across enterocytes via Pept1 or were catabolized to amino acids by aminopeptidase N (Wang et al., 2020). Dalmasso et al. (2008) reported that butyrate enhanced the expression and activity of Pept1 in mice. Liu et al. (2017) found that SB supplementation induced Pept1 expression in juvenile grass carp. Consistent with these previous studies, the present results showed that CBH and SB upregulated the expression of Pept1. B0AT is a Na+-dependent neutral amino acid transporter (Wang et al., 2020). The present authors were unaware of any exploration of the effect of butyrate on the expression of B0AT, and it was found here that B0AT transcripts were induced by CBL. Hence, the above findings demonstrated that CB and SB were likely able to increase capacity for the absorption of nutrients.

Gut microbiota affected the parameters of fitness, such as survival, phenotypic plasticity, and reproductive performance of animals (Zilber-Rosenberg and Rosenberg, 2008). Dietary butyrate functioned as a bactericidal agent because it can lower the pH in the crop and gizzard and proximal intestine, to control harmful bacteria, such as Salmonella spp., Escherichia coli, and Campylobacter jejuni (Van Deun et al., 2008). Hens provided with CB had reduced cecal E. coli and increased
Bifidobacterium (Zhan et al., 2019). Czerwiński et al. (2012) found that dietary SB increased total bacterial numbers and Lactobacillus counts in ileal and cecal contents of chickens. Supplementation of laying hens reduced total bacteria and ileal E. coli numbers (Jahanian and Golshadi, 2015). In the present study, the cecal microbiota structure of the yellow-feathered breeder hens was examined. Compared with the controls, breeder hens given CBH and CBL had more Firmicutes at the phylum level. As CB belonged to Bacillaceae family and Clostridium genus, the relative abundance of Bacillaceae and Clostridium was further determined. The present results suggested that CBL increased the presence of Bacillaceae, though abundance of Clostridium was unaffected by CB, SB, and BAG treatments. Increased Firmicutes and Bacillaceae in CB treatments might simply stem from the dietary addition of CB. Firmicutes bacteria provide a good index of the state of the intestine. For example, Bacillaceae, Lactobacillus, and Lactococcus could suppress the production of inflammatory cytokines and pathogen-induced disruption of intestine function (Li et al., 2009; Zheng et al., 2017; Dowdell et al., 2020). Dietary CB supplementation of young pigs promoted growth performance and increased the Bacillus level (Chen et al., 2018). It is likely, therefore, that elevated abundance of Firmicutes and Bacillaceae induced by CB might promote the growth and health of yellow-feathered breeder hens. Additionally, in agreement with the study of Duan et al. (2018), the abundance of Proteobacteria in the shrimp Litopenaeus vannamei was reduced by diets containing 2.5 and 5.0 × 10⁹ CFU/kg, and CBH here, in breeder hens, also decreased the abundance of Proteobacteria. Thus, the altered population structure of the gut microbiota caused by dietary CB might contribute to the improved performance of yellow-feathered breeder hens.

LDA and LEfSe analysis showed increased Shuttleworthia, Lactobacillus, Barnesiellaceae, and Bacteroides in CBH, CBL,

SB, and BAG treatments, respectively. *Shuttleworthia* had a relationship with carbohydrate and lipid metabolic pathways and thus contributed to weight gain and growth performance in broiler chickens (Lee et al., 2017). *Lactobacillus* generally improved the gastrointestinal tract environment and protected the gut from pathogens (Dicks and Botes, 2010). Moreover, although the roles of Barnesiellaceae were not well known, research suggested that the Behçet’s disease and the use of antibiotic led to decreased abundance of Barnesiellaceae (van der Houwen et al., 2020). Additionally, meta-analysis revealed that lower level of *Bacteroides* was associated with intestinal inflammation (Zhou and Zhi, 2016). Finally, co-occurrence patterns of intestinal microbes were employed to investigate the microbial interactions. In the present study, the positive correlation of the microbial networks in the CBH and BAG treatments was more than those in the controls, while the negative correlation of the microbial networks in the CBH and BAG groups was less than those in controls, which could be interpreted as a reduction in competitive relationships within intestinal microbes (Fan et al., 2018).

### CONCLUSION

In conclusion, the supplementation with CB and BAG in the diets of breeder hens increased the reproductive performance and improved the egg quality and intestinal morphology. CB treatment also promoted the hatching performance of breeder hens and growth performance of offspring. These effects might result from the regulation of cytokines, nutrient transporters, apoptosis, and profiles of gut microbiota. The beneficial effects described were more obvious with CBH treatment than the CBL treatment, as CBH induced the higher hatchability, eggshell thickness, jejunal crypt depth, and BAT expression. Although SB had no beneficial effect on reproductive performance, egg
