HARMONIC FUNCTIONS, CONJUGATE HARMONIC FUNCTIONS AND THE HARDY SPACE $H^1$ IN THE RATIONAL DUNKL SETTING

JEAN-PHILIPPE ANKER, JACEK DZIUBAŃSKI, AGNIESZKA HEJNA

Abstract. In this work we extend the theory of the classical Hardy space $H^1$ to the rational Dunkl setting. Specifically, let $\Delta$ be the Dunkl Laplacian on a Euclidean space $\mathbb{R}^N$. On the half-space $\mathbb{R}_+ \times \mathbb{R}^N$, we consider systems of conjugate ($\partial^2_t + \Delta_x$)-harmonic functions satisfying an appropriate uniform $L^1$ condition. We prove that the boundary values of such harmonic functions, which constitute the real Hardy space $H^1$, can be characterized in several different ways, namely by means of atoms, Riesz transforms, maximal functions or Littlewood-Paley square functions.

1. Introduction

Real Hardy spaces on $\mathbb{R}^N$ have their origin in studying holomorphic functions of one variable in the upper half-plane $\mathbb{R}^2_+ = \{ z = x + iy \in \mathbb{C} : y > 0 \}$. The theorem of Burkholder, Gundy, and Silverstein [4] asserts that a real-valued harmonic function $u$ on $\mathbb{R}^2_+$ is the real part of a holomorphic function $F(z) = u(z) + iv(z)$ satisfying the $L^p$ condition

$$\sup_{y>0} \int_{\mathbb{R}} |F(x + iy)|^p \, dx < \infty, \quad 0 < p < \infty,$$

if and only if the nontangential maximal function $u^*(x) = \sup_{|x-x'|<y} |u(x'+iy)|$ belongs to $L^p(\mathbb{R})$. Here $0 < p < \infty$. The $N$-dimensional theory was then developed in Stein and Weiss [26] and Fefferman and Stein [12], where the notion of holomorphy was replaced by conjugate harmonic functions. To be more precise, a system of $C^2$ functions

$$u(x_0, x_1, \ldots, x_N) = (u_0(x_0, x_1, \ldots, x_N), u_1(x_0, x_1, \ldots, x_N), \ldots, u_N(x_0, x_1, \ldots, x_N)),$$

where $x_0 > 0$, satisfies the generalized Cauchy-Riemann equations if

$$(1.1) \quad \frac{\partial u_j}{\partial x_i} = \frac{\partial u_i}{\partial x_j} \quad \forall \ 0 \leq i \neq j \leq N \quad \text{and} \quad \sum_{j=0}^{N} \frac{\partial u_j}{\partial x_j} = 0.$$
One says that \( u \) has the \( L^p \) property if

\[
(1.2) \quad \sup_{x_0 > 0} \int_{\mathbb{R}^N} |u(x_0, x_1, \ldots, x_N)|^p \, dx_1 \ldots dx_N < \infty.
\]

As in the case \( N = 1 \), if \( 1 - \frac{1}{N} < p < \infty \) and \( u_0(x_0, x_1, \ldots, x_N) \) is a harmonic function, there is a system \( u = (u_0, u_1, \ldots, u_N) \) of \( C^2 \) functions satisfying (1.1) and (1.2) if and only if

\[
u_0^*(x) = \sup_{\|x - x'\| < x_0} |u_0(x_0, x')|
\]

belongs to \( L^p(\mathbb{R}^N) \). Here \( x = (x_1, \ldots, x_N) \in \mathbb{R}^N \) and similarly \( x' = (x'_1, \ldots, x'_N) \). Then \( u_0 \) has a limit \( f_0 \) in the sense of distributions, as \( x_0 \searrow 0 \), and \( u_0 \) is the Poisson integral of \( f_0 \). It turns out that the set of all distributions obtained in this way, which form the so-called real Hardy space \( H^p(\mathbb{R}^N) \), can be equivalently characterized in terms of real analysis (see [12]), namely by means of various maximal functions, square functions or Riesz transforms. An other important contribution to this theory lies in the atomic decomposition introduced by Coifman [5] and extended to spaces of homogeneous type by Coifman and Weiss [7].

The goal of this paper is to study harmonic functions, conjugate harmonic functions, and related Hardy space \( H^1 \) for the Dunkl Laplacian \( \Delta \) (see Section 2). We shall prove that these objects have properties analogous to the classical ones. In particular the related real Hardy space \( H^1_{\Delta} \), which can be defined as the set of boundary values of \( (\partial^2 + \Delta_x) \)-harmonic functions satisfying a relevant \( L^1 \) property, can be characterized by appropriate maximal functions, square functions, Riesz transforms or atomic decompositions. Apart from the square function characterization, this was achieved previously in [2] and [9] in the one-dimensional case, as well as in the product case.

### 2. Statement of the results

In this section we first collect basic facts concerning Dunkl operators, the Dunkl Laplacian, and the corresponding heat and Poisson semigroups. For details we refer the reader to [8], [21] and [22]. Next we state our main results.

In the Euclidean space \( \mathbb{R}^N \), equipped with a scalar product \( \langle x, y \rangle \), the reflection \( \sigma_\alpha \) with respect to the hyperplane \( \alpha^\perp \) orthogonal to a nonzero vector \( \alpha \) is given by

\[
\sigma_\alpha(x) = x - 2 \frac{\langle x, \alpha \rangle}{\|\alpha\|^2} \alpha.
\]

A finite set \( R \subset \mathbb{R}^N \setminus \{0\} \) is called a root system if \( \sigma_\alpha(R) = R \) for every \( \alpha \in R \). We shall consider normalized reduced root systems, that is, \( \|\alpha\|^2 = 2 \) for every \( \alpha \in R \). The finite group \( G \) generated by the reflections \( \sigma_\alpha \) is called the Weyl group (reflection group) of the root system. We shall denote by \( \mathcal{O}(x) \), resp. \( \mathcal{O}(B) \) the \( G \)-orbit of a point \( x \in \mathbb{R}^N \), resp. a subset \( B \subset \mathbb{R}^N \). A multiplicity function is a \( G \)-invariant function \( k : R \to \mathbb{C} \), which will be fixed and \( \geq 0 \) throughout this paper.
Given a root system $R$ and a multiplicity function $k$, the Dunkl operators $T_\xi$ are the following deformations of directional derivatives $\partial_\xi$ by difference operators:

$$T_\xi f(x) = \partial_\xi f(x) + \sum_{\alpha \in R} \frac{k(\alpha)}{2} \frac{f(x) - f(\sigma_\alpha(x))}{\langle \alpha, x \rangle} \langle \alpha, \xi \rangle$$

$$= \partial_\xi f(x) + \sum_{\alpha \in R^+} k(\alpha) \frac{f(x) - f(\sigma_\alpha(x))}{\langle \alpha, x \rangle} \langle \alpha, \xi \rangle.$$

Here $R^+$ is any fixed positive subsystem of $R$. The Dunkl operators $T_\xi$, which were introduced in [8], commute pairwise and are skew-symmetric with respect to the $G$-invariant measure $dw(x) = w(x) dx$, where

$$w(x) = \prod_{\alpha \in R} |\langle \alpha, x \rangle|^{k(\alpha)} = \prod_{\alpha \in R^+} |\langle \alpha, x \rangle|^{2k(\alpha)}.$$

Set $T_j = T_e_j$, where $\{e_1, \ldots, e_N\}$ is the canonical basis of $\mathbb{R}^N$. The Dunkl Laplacian associated with $R$ and $k$ is the differential-difference operator $\Delta = \sum_{j=1}^n T_j^2$, which acts on $C^2$ functions by

$$\Delta f(x) = \Delta_{euc} f(x) + \sum_{\alpha \in R} k(\alpha) \delta_\alpha f(x) = \Delta_{euc} f(x) + 2 \sum_{\alpha \in R^+} k(\alpha) \delta_\alpha f(x),$$

where

$$\delta_\alpha f(x) = \frac{\partial f(x)}{\langle \alpha, x \rangle} - \frac{f(x) - f(\sigma_\alpha(x))}{\langle \alpha, x \rangle^2}.$$

The operator $\Delta$ is essentially self-adjoint on $L^2(dw)$ (see for instance [1, Theorem 3.1]) and generates the heat semigroup

$$(2.1) \quad H_tf(x) = e^{t\Delta} f(x) = \int_{\mathbb{R}^N} h_t(x, y) f(y) dw(y).$$

Here the heat kernel $h_t(x, y)$ is a $C^\infty$ function in all variables $t > 0$, $x \in \mathbb{R}^N$, $y \in \mathbb{R}^N$, which satisfies

$$h_t(x, y) = h_t(y, x) > 0 \quad \text{and} \quad \int_{\mathbb{R}^N} h_t(x, y) dw(y) = 1.$$  

Notice that (2.1) defines a strongly continuous semigroup of linear contractions on $L^p(dw)$, for every $1 \leq p < \infty$.

The Poisson semigroup $P_t = e^{-t\sqrt{-\Delta}}$ is given by the subordination formula

$$(2.2) \quad P_tf(x) = \pi^{-1/2} \int_0^\infty e^{-u} \exp\left(\frac{t^2}{4u}\Delta\right) f(x) \frac{du}{\sqrt{u}}$$

and solves the boundary value problem

$$\begin{cases} (\partial_t^2 + \Delta_x) u(t, x) = 0 \\ u(0, x) = f(x) \end{cases}$$
in the upper half-space \( \mathbb{R}^{1+N}_+ = (0, \infty) \times \mathbb{R}^N \subset \mathbb{R}^{1+N} \). Let \( e_0 = (1,0,\ldots,0), \) \( e_1 = (0,1,\ldots,0), \ldots, e_N = (0,0,\ldots,1) \) be the canonical basis in \( \mathbb{R}^{1+N} \). In order to unify our notation we shall denote the variable \( t \) by \( x_0 \) and set \( T_0 = \partial_{x_0} \).

Our goal is to study real harmonic functions of the operator

\[
(2.3) \quad \mathcal{L} = T_0^2 + \Delta = \sum_{j=0}^{N} T_j^2.
\]

The operator \( \mathcal{L} \) is the Dunkl Laplacian associated with the root system \( R \), considered as a subset of \( \mathbb{R}^{1+N} \) under the embedding \( R \subset \mathbb{R}^N \hookrightarrow \mathbb{R} \times \mathbb{R}^N \).

We say that a system

\[ u = (u_0, u_1, \ldots, u_N), \quad \text{where} \quad u_j = u_j(x_0, x_1, \ldots, x_N) \quad \forall 0 \leq j \leq N, \]

of \( C^1 \) real functions on \( \mathbb{R}^{1+N}_+ \) satisfies the generalized Cauchy-Riemann equations if

\[
(2.4) \quad \begin{cases} 
T_i u_j = T_j u_i & \forall 0 \leq i \neq j \leq N, \\
\sum_{j=0}^{N} T_j u_j = 0.
\end{cases}
\]

In this case each component \( u_j \) is \( \mathcal{L} \)-harmonic, i.e., \( \mathcal{L} u_j = 0 \).

We say that a system \( u \) of \( C^2 \) real \( \mathcal{L} \)-harmonic functions on \( \mathbb{R}^{1+N}_+ \) belongs to the Hardy space \( \mathcal{H}^1 \) if it satisfies both \( (2.4) \) and the \( L^1 \) condition

\[
\|u\|_{\mathcal{H}^1} = \sup_{x_0 > 0} \|u(x_0, \cdot)\|_{L^1(dw)} = \sup_{x_0 > 0} \int_{\mathbb{R}^N} |u(x_0, x)| \, dw(x) < \infty,
\]

where \( |u(x_0, x)| = \left( \sum_{j=0}^{N} |u_j(x_0, x)|^2 \right)^{1/2} \).

We are now ready to state our first main result.

**Theorem 2.5.** Let \( u_0 \) be a \( \mathcal{L} \)-harmonic function in the upper half-space \( \mathbb{R}^{1+N}_+ \). Then there are \( \mathcal{L} \)-harmonic functions \( u_j \) \((j = 1, \ldots, N)\) such that \( u = (u_0, u_1, \ldots, u_N) \) belongs to \( \mathcal{H}^1 \) if and only if the nontangential maximal function

\[
(2.6) \quad u_0^*(x) = \sup_{\|x'-x\| < x_0} |u_0(x_0, x')|
\]

belongs to \( L^1(dw) \). In this case, the norms \( \|u_0\|_{L^1(dw)} \) and \( \|u\|_{\mathcal{H}^1} \) are moreover equivalent.

If \( u \in \mathcal{H}^1 \), we shall prove that the limit \( f(x) = \lim_{x_0 \to 0} u_0(x_0, x) \) exists in \( L^1(dw) \) and \( u_0(x_0, x) = P_{x_0} f(x) \). This leads to consider the so-called real Hardy space

\[ H^1_{\Delta} = \{ f(x) = \lim_{x_0 \to 0} u_0(x_0, x) \mid (u_0, u_1, \ldots, u_N) \in \mathcal{H}^1 \}, \]

equipped with the norm

\[
\|f\|_{H^1_{\Delta}} = \|(u_0, u_1, \ldots, u_N)\|_{\mathcal{H}^1}.
\]

Let us denote by

\[
\mathcal{M}_P f(x) = \sup_{\|x'-x\| < t} |P_t f(x')|
\]
the nontangential maximal function associated with the Poisson semigroup $P_t = e^{-t\Delta}$. According to Theorem 2.5, $H^1_{\Delta}$ coincides with the following subspace of $L^1(dw)$:

$$H^1_{\max, P} = \{ f \in L^1(dw) \mid \| M_P f \|_{L^1(dw)} < \infty \}.$$ 

Moreover, the norms $\| f \|_{H^1_{\Delta}}$ and $\| M_P f \|_{L^1(dw)}$ are equivalent.

Our task is to prove other characterizations of $H^1_{\Delta}$ by means of real analysis.

**A. Characterization by the heat maximal function.** Let

$$M_H f(x) = \sup_{|x-x'|<t} |H_t f(x')|$$

be the nontangential maximal function associated with the heat semigroup $H_t = e^{t\Delta}$ and set

$$H^1_{\max, H} = \{ f \in L^1(dw) \mid \| M_H f \|_{L^1(dw)} < \infty \}.$$ 

**Theorem 2.7.** The spaces $H^1_{\Delta}$ and $H^1_{\max, H}$ coincide and the corresponding norms $\| f \|_{H^1_{\Delta}}$ and $\| M_H f \|_{L^1(dw)}$ are equivalent.

**B. Characterization by square functions.** For every $1 \leq p \leq \infty$, the operators $Q_t = t\sqrt{-\Delta} e^{-t\Delta}$ are uniformly bounded on $L^p(dw)$ (this is a consequence of the estimates (4.4), (5.8) and (5.5)). Consider the square function

$$(2.8) \quad S f(x) = \left( \int \int_{|x-y|<t} |Q_t f(y)|^2 \frac{dt \, dw(y)}{tw(B(x, t))} \right)^{1/2}$$

and the space

$$H^1_{\text{square}} = \{ f \in L^1(dw) \mid \| S f \|_{L^1(dw)} < \infty \}.$$ 

**Theorem 2.9.** The spaces $H^1_{\Delta}$ and $H^1_{\text{square}}$ coincide and the corresponding norms $\| f \|_{H^1_{\Delta}}$ and $\| S f \|_{L^1(dw)}$ are equivalent.

**Remark 2.10.** The square function characterization of $H^1_{\Delta}$ is also valid for $Q_t = t^2 \Delta e^{t^2\Delta}$.

**C. Characterization by Riesz transforms.** The Riesz transforms, which are defined in the Dunkl setting by

$$R_j f = T_j (-\Delta)^{-1/2} f$$

(see Section 8), are bounded operators on $L^p(dw)$, for every $1 < p < \infty$ (cf. [3]). In the limit case $p = 1$, they turn out to be bounded operators from $H^1_{\Delta}$ into $H^1_{\Delta} \subset L^1(dw)$. This leads to consider the space

$$H^1_{\text{Riesz}} = \{ f \in L^1(dw) \mid \| R_j f \|_{L^1(w)} < \infty \forall 1 \leq j \leq N \}.$$ 

**Theorem 2.11.** The spaces $H^1_{\Delta}$ and $H^1_{\text{Riesz}}$ coincide and the corresponding norms $\| f \|_{H^1_{\Delta}}$ and

$$\| f \|_{H^1_{\text{Riesz}}} := \| f \|_{L^1(dw)} + \sum_{j=1}^N \| R_j f \|_{L^1(dw)}$$

are equivalent.
D. Characterization by atomic decompositions. Let us define atoms in the spirit of [15]. Given a Euclidean ball $B$ in $\mathbb{R}^N$, we shall denote its radius by $r_B$ and its $G$-orbit by $O(B)$. For any positive integer $M$, let $D(\Delta^M)$ be the domain of $\Delta^M$ as an (unbounded) operator on $L^2(dw)$.

**Definition 2.12.** Let $1 < q \leq \infty$ and let $M$ be a positive integer. A function $a \in L^2(dw)$ is said to be a $(1, q, M)$-atom if there exist $b \in D(\Delta^M)$ and a ball $B$ such that

- $a = \Delta^M b$,
- $\text{supp} (\Delta^\ell b) \subset O(B) \ \forall \ 0 \leq \ell \leq M$,
- $\| (r_B^2 \Delta)^\ell b \|_{L^q(dw)} \leq r^{2M} w(B)^{\frac{1}{q} - 1} \ \forall \ 0 \leq \ell \leq M$.

**Definition 2.13.** A function $f$ belongs to $H^1_{(1,q,M)}$ if there are $\lambda_j \in \mathbb{C}$ and $(1, q, M)$-atoms $a_j$ such that

$$f = \sum_j \lambda_j a_j. \quad (2.14)$$

In this case, set

$$\|f\|_{H^1_{(1,q,M)}} = \inf \left\{ \sum_j |\lambda_j| \right\},$$

where the infimum is taken over all representations (2.14).

**Theorem 2.15.** The spaces $H^1_\Delta$ and $H^1_{(1,q,M)}$ coincide and the corresponding norms are equivalent.

In the one-dimensional case and in the product case considered in [2] and [9], the Dunkl kernel can be expressed explicitly in terms of classical special functions (Bessel functions or the confluent hypergeometric function). Thus its behavior is fully understood, and consequently all kernels involved in the definitions above. In the general case considered in the present paper, no such information is available. Therefore an essential part of our work consists in deriving estimates of the Dunkl kernel, of the heat kernel, of the Poisson kernel, and of their derivatives (see the end of Section 3, Section 4 and Section 5). These estimates, which are in a spirit of analysis on spaces of homogeneous type, allow us to build up the theory of the Hardy space $H^1$ in the Dunkl setting.

Let us briefly describe the organization of the proofs of the results. Clearly, $H^1_{(1,q_1,M)} \subset H^1_{(1,q_2,M)}$ for $1 < q_2 \leq q_1 \leq \infty$. The proof $(u_0, u_1, \ldots, u_N) \in \mathcal{H}^1_\Delta$ implies $u_0^* \in L^1(dw)$, which is actually the inclusion $H^1_\Delta \subset H^1_{\text{max}, P}$, is presented in Section 7, see Proposition 7.12. The proof is based on $L$-subharmonicity of certain function constructed from $u$ (see Section 6). The converse to Proposition 7.12 is proved at the very end of Section 11. Inclusions: $H^1_\Delta \subset H^1_{\text{Riesz}} \subset H^1_\Delta$ are shown in Section 8. Further, $H^1_{(1,q,M)} \subset H^1_{\text{Riesz}}$ for $M$ large is proved in Section 9. The proofs of $H^1_{\text{max}, H} \subset H^1_{\text{max}, P} \subset H^1_{(1,\infty,M)}$ for every $M \geq 1$ are presented in Section 11. Inclusion: $H^1_{(1,q,M)} \subset H^1_{\text{max}, H}$ for every $M \geq 1$ is proved in Section 12. Finally $H^1_{(1,2,M)} \subset H^1_{\text{square}} \subset H^1_{(1,2,M)}$ are established in Section 13.
3. Dunkl kernel, Dunkl transform and Dunkl translations

The purpose of this section is to collect some facts about the Dunkl kernel, the Dunkl transform and Dunkl translations. General references are [8], [21], [22]. At the end of this section we shall derive estimates for the Dunkl translations of radial functions. These estimates will be used later to obtain bounds for the heat kernel and for the Poisson kernel, as well as for their derivatives, and furthermore upper and lower bounds for the Dunkl kernel.

We begin with some notation. Given a root system $R$ in $\mathbb{R}^N$ and a multiplicity function $k \geq 0$, let
\begin{equation}
\gamma = \sum_{\alpha \in R^+} k(\alpha) \quad \text{and} \quad N = N + 2\gamma.
\end{equation}
The number $N$ is called the homogeneous dimension, because of the scaling property
\[ w(B(tx, tr)) = t^N w(B(x, r)). \]
Observe that \(^1\)
\[ w(B(x, r)) \sim r^N \prod_{\alpha \in R} (|\langle \alpha, x \rangle| + r)^{k(\alpha)}. \]
Thus the measure $w$ is doubling, that is, there is a constant $C > 0$ such that
\[ w(B(x, 2r)) \leq C w(B(x, r)). \]
Moreover, there exists a constant $C \geq 1$ such that, for every $x \in \mathbb{R}^N$ and for every $R \geq r > 0$,
\begin{equation}
C^{-1} \left( \frac{R}{r} \right)^N \leq \frac{w(B(x, R))}{w(B(x, r))} \leq C \left( \frac{R}{r} \right)^N.
\end{equation}
Set
\[ V(x, y, t) = \max \{ w(B(x, t)), w(B(y, t)) \}. \]
Finally, let $d(x, y) = \min_{\sigma \in G} \| x - \sigma(y) \|$ denote the distance between two $G$-orbits $O(x)$ and $O(y)$. Obviously, $\{ y \in \mathbb{R}^N \mid d(y, x) < r \} = O(B(x, r))$ and
\[ w(B(x, r)) \leq w(O(B(x, r))) \leq |G| w(B(x, r)). \]

**Dunkl kernel.** For fixed $x \in \mathbb{R}^N$, the Dunkl kernel $y \mapsto E(x, y)$ is the unique solution to the system
\[ \begin{cases} 
T_\xi f = \langle \xi, x \rangle f \quad &\forall \xi \in \mathbb{R}^N, \\
f(0) = 1.
\end{cases} \]
The following integral formula was obtained by Rösler [19]:
\begin{equation}
E(x, y) = \int_{\mathbb{R}^N} e^{(y-x) \eta} d\mu_x(\eta),
\end{equation}
\(^1\)The symbol $\sim$ between two positive expressions means that their ratio is bounded between two positive constants.
where $\mu_x$ is a probability measure supported in the convex hull $\text{conv } O(x)$ of the $G$-orbit of $x$. The function $E(x, y)$, which generalizes the exponential function $e^{\langle x, y \rangle}$, extends holomorphically to $\mathbb{C}^N \times \mathbb{C}^N$ and satisfies the following properties:

- $E(0, y) = 1$ $\forall y \in \mathbb{C}^N$,
- $E(x, y) = E(y, x)$ $\forall x, y \in \mathbb{C}^N$,
- $E(\lambda x, y) = E(x, \lambda y)$ $\forall \lambda \in \mathbb{C}$, $\forall x, y \in \mathbb{C}^N$,
- $E(\sigma(x), \sigma(y)) = E(x, y)$ $\forall \sigma \in G$, $\forall x, y \in \mathbb{C}^N$,
- $E(x, y) = E(\bar{x}, \bar{y})$ $\forall x, y \in \mathbb{C}^N$,
- $E(x, y) > 0$ $\forall x, y \in \mathbb{R}^N$,
- $|E(ix, y)| \leq 1$ $\forall x, y \in \mathbb{R}^N$,
- $|\partial_x^\alpha E(x, y)| \leq \|x\|^{|\alpha|} \max_{\sigma \in G} e^{\Re \langle \sigma(x), y \rangle}$ $\forall \alpha \in \mathbb{N}^N$, $\forall x \in \mathbb{R}^N$, $\forall y \in \mathbb{C}^N$.

**Dunkl transform.** The Dunkl transform is defined on $L^1(dw)$ by

$$\mathcal{F} f(\xi) = c_k^{-1} \int_{\mathbb{R}^N} f(x) E(x, -i\xi) dw(x),$$

where

$$c_k = \int_{\mathbb{R}^N} e^{-\frac{\|x\|^2}{2}} dw(x) > 0.$$

The following properties hold for the Dunkl transform (see [16], [22]):

- The Dunkl transform is a topological automorphisms of the Schwartz space $\mathcal{S}(\mathbb{R}^N)$.
- $(\text{Inversion formula})$ For every $f \in \mathcal{S}(\mathbb{R}^N)$ and actually for every $f \in L^1(dw)$ such that $\mathcal{F} f \in L^1(dw)$, we have
  $$f(x) = (\mathcal{F})^2 f(-x) \quad \forall x \in \mathbb{R}^N.$$
- $(\text{Plancherel Theorem})$ The Dunkl transform extends to an isometric automorphism of $L^2(dw)$.
- The Dunkl transform of a radial function is again a radial function.
- $(\text{Scaling})$ For $\lambda \in \mathbb{R}^*$, we have
  $$\mathcal{F}(f_\lambda)(\xi) = \mathcal{F} f(\lambda \xi),$$
  where $f_\lambda(x) = |\lambda|^{-N} f(\lambda^{-1}x)$.
- Via the Dunkl transform, the Dunkl operator $T_\eta$ corresponds to the multiplication by $\pm i \langle \eta, \cdot \rangle$. Specifically,
  $$\begin{cases} 
  \mathcal{F}(T_\eta f) = i \langle \eta, \cdot \rangle \mathcal{F} f, \\
  T_\eta(\mathcal{F} f) = -i \mathcal{F}(\langle \eta, \cdot \rangle f).
  \end{cases}$$

In particular, $\mathcal{F}(\Delta f)(\xi) = -\|\xi\|^2 \mathcal{F} f(\xi)$.

---

2 Here and subsequently, $\mathbb{N}$ denotes the set of nonnegative integers.
Dunkl translations and Dunkl convolution. The Dunkl translation \( \tau_{x}f \) of a function \( f \in \mathcal{S}(\mathbb{R}^{N}) \) by \( x \in \mathbb{R}^{N} \) is defined by

\[
\tau_{x}f(y) = c_{k}^{-1} \int_{\mathbb{R}^{N}} E(i\xi, x) E(i\xi, y) \mathcal{F}f(\xi) \, dw(\xi).
\]

Notice the following properties of Dunkl translations:

- each translation \( \tau_{x} \) is a continuous linear map of \( \mathcal{S}(\mathbb{R}^{N}) \) into itself, which extends to a contraction on \( L^{2}(dw) \),
- \( \text{(Identity)} \) \( \tau_{0} = I \),
- \( \text{(Symmetry)} \) \( \tau_{x}f(y) = \tau_{y}f(x) \) \( \forall x, y \in \mathbb{R}^{N}, \forall f \in \mathcal{S}(\mathbb{R}^{N}) \),
- \( \text{(Scaling)} \) \( \tau_{x}(f_{\lambda}) = (\tau_{-1}x)f_{\lambda} \) \( \forall \lambda > 0, \forall x \in \mathbb{R}^{N}, \forall f \in \mathcal{S}(\mathbb{R}^{N}) \),
- \( \text{(Commutativity)} \) the Dunkl translations \( \tau_{x} \) and the Dunkl operators \( T_{x} \) all commute,
- \( \text{(Skew-symmetry)} \)

\[
\int_{\mathbb{R}^{N}} \tau_{x}f(y) \, g(y) \, dw(y) = \int_{\mathbb{R}^{N}} f(y) \, \tau_{-x}g(y) \, dw(y) \quad \forall x \in \mathbb{R}^{N}, \forall f, g \in \mathcal{S}(\mathbb{R}^{N}).
\]

The latter formula allows us to define the Dunkl translations \( \tau_{x}f \) in the distributional sense for \( f \in L^{p}(dw) \) with \( 1 \leq p \leq \infty \). In particular,

\[
\int_{\mathbb{R}^{N}} \tau_{x}f(y) \, dw(y) = \int_{\mathbb{R}^{N}} f(y) \, dw(y) \quad \forall x \in \mathbb{R}^{N}, \forall f \in \mathcal{S}(\mathbb{R}^{N}).
\]

Finally, notice that \( \tau_{x}f \) is given by (3.4), if \( f \in L^{1}(dw) \) and \( \mathcal{F}f \in L^{1}(dw) \).

The Dunkl convolution of two reasonable functions (for instance Schwartz functions) is defined by

\[
(f \ast g)(x) = c_{k} \mathcal{F}^{-1}[(\mathcal{F}f)(\mathcal{F}g)](x) = \int_{\mathbb{R}^{N}} (\mathcal{F}f)(\xi) (\mathcal{F}g)(\xi) E(x, i\xi) \, dw(\xi) \quad \forall x \in \mathbb{R}^{N}
\]
or, equivalently, by

\[
(f \ast g)(x) = \int_{\mathbb{R}^{N}} f(y) \, \tau_{x}g(-y) \, dw(y) \quad \forall x \in \mathbb{R}^{N}.
\]

Dunkl translations of radial functions. The following specific formula was obtained by Rösler [20] for the Dunkl translations of (reasonable) radial functions \( f(x) = \tilde{f}(||x||) \):

\[
\tau_{x}f(-y) = \int_{\mathbb{R}^{N}} (\tilde{f} \circ A)(x, y, \eta) \, d\mu_{x}(\eta) \quad \forall x, y \in \mathbb{R}^{N}.
\]

Here

\[
A(x, y, \eta) = \sqrt{||x||^{2} + ||y||^{2} - 2\langle x, y \rangle} = \sqrt{||x||^{2} - ||\eta||^{2} + ||y - \eta||^{2}}
\]

and \( \mu_{x} \) is the probability measure occurring in (3.3), which is supported in \( \text{conv } \mathcal{O}(x) \).

In the remaining part of this section, we shall derive estimates for the Dunkl translations of certain radial functions. Let us begin with the following elementary estimates (see, e.g., [3]), which hold for \( x, y \in \mathbb{R}^{N} \) and \( \eta \in \text{conv } \mathcal{O}(x) \):

\[
A(x, y, \eta) \geq d(x, y)
\]
and

\[
\begin{cases}
\| \nabla_y \{ A(x, y, \eta)^2 \} \| \leq 2 A(x, y, \eta), \\
| \partial_\beta \{ A(x, y, \eta)^2 \} | \leq 2 & \text{if } |\beta| = 2, \\
\partial_\beta \{ A(x, y, \eta)^2 \} = 0 & \text{if } |\beta| > 2.
\end{cases}
\]  

(3.7)

Hence

\[
\| \nabla_y A(x, y, \eta) \| \leq 1
\]

and, more generally,

\[
| \partial_\beta (\Theta A)(x, y, \eta) | \leq C_\beta A(x, y, \eta)^m - |\beta| \quad \forall \beta \in \mathbb{N}^N,
\]

if \( \Theta \in C^\infty(\mathbb{R} \setminus \{0\}) \) is a homogeneous symbol of order \( m \in \mathbb{R} \), i.e.,

\[
| (d/dx)^\beta \Theta(x) | \leq C_\beta |x|^{m-\beta} \quad \forall x \in \mathbb{R} \setminus \{0\}, \forall \beta \in \mathbb{N}.
\]

Similarly,

\[
| \partial_\beta (\tilde{\Theta} A)(x, y, \eta) | \leq C_\beta \left\{ 1 + A(x, y, \eta) \right\}^{m-|\beta|} \quad \forall \beta \in \mathbb{N}^N,
\]

if \( \tilde{\Theta} \in C^\infty(\mathbb{R}) \) is an even inhomogeneous symbol of order \( m \in \mathbb{R} \), i.e.,

\[
| (d/dx)^\beta \tilde{\Theta}(x) | \leq C_\beta (1 + |x|)^{m-\beta} \quad \forall x \in \mathbb{R}, \forall \beta \in \mathbb{N}.
\]

Consider the radial function

\[
q(x) = c_M (1 + \|x\|^2)^{-M/2}
\]

on \( \mathbb{R}^N \), where \( M > N \) and \( c_M > 0 \) is a normalizing constant such that \( \int_{\mathbb{R}^N} q(x) \, dw(x) = 1 \). Notice that \( \tilde{q}(x) = c_M (1 + x^2)^{-M/2} \) is an even inhomogeneous symbol of order \(-M\). The following estimate holds for the translates \( q_t(x, y) = \tau_x q_t(-y) \) of \( q_t(x) = t^{-N} q(t^{-1} x) \).

**Proposition 3.9.** There exists a constant \( C > 0 \) (depending on \( M \)) such that

\[
0 \leq q_t(x, y) \leq CV(x, y, t)^{-1} \quad \forall t > 0, \forall x, y \in \mathbb{R}^N.
\]

**Proof.** By scaling we can reduce to \( t = 1 \). Fix \( x, y \in \mathbb{R}^N \). By continuity, the function \( y' \mapsto q_1(x, y') \) reaches a maximum \( K = q_1(x, y_0) \geq 0 \) on the ball

\[
B = B(y, 1) = \{ y' \in \mathbb{R}^N | \| y' - y \| \leq 1 \}.
\]
For every $y' \in B$, we have
\begin{align*}
0 \leq q_1(x, y_0) - q_1(x, y') &= \int_{\mathbb{R}^N} \{ (\bar{q} \circ A)(x, y_0, \eta) - (\bar{q} \circ A)(x, y', \eta) \} \, d\mu_x(\eta) \\
&= \int_{\mathbb{R}^N} \int_0^1 \frac{\partial}{\partial s} (\bar{q} \circ A)(x, y + s(y_0 - y'), \eta) \, ds \, d\mu_x(\eta) \\
&\leq \|y_0 - y'\| \int_{\mathbb{R}^N} \int_0^1 |(\bar{q} \circ A)(x, y_s, \eta)| \, ds \, d\mu_x(\eta) \\
&\leq M \|y_0 - y'\| \int_{\mathbb{R}^N} \int_0^1 (\bar{q} \circ A)(x, y_s, \eta) \, ds \, d\mu_x(\eta) \\
&= M \|y_0 - y'\| \int_0^1 q_1(x, y_s) \, ds \\
&\leq M \|y_0 - y'\| K.
\end{align*}

Here we have used (3.8) and the elementary estimate
\[ |\bar{q}'(x)| \leq M \bar{q}(x) \quad \forall \, x \in \mathbb{R}. \]

Hence
\[ q_1(x, y') \geq q_1(x, y_0) - |q_1(x, y_0) - q_1(x, y')| \geq K - \frac{K}{2} = \frac{K}{2}, \]

if $y' \in \bar{B} \cap B(y_0, r)$ with $r = \frac{1}{\sqrt{M}}$. Moreover, as $w(\bar{B} \cap B(y_0, r)) \sim w(\bar{B})$, we have
\begin{align*}
1 &= \int_{\mathbb{R}^N} q_1(x, y') \, dw(y') \\
&\geq \int_{B \cap B(y_0, r)} q_1(x, y') \, dw(y') \\
&\geq \frac{K}{2} w(\bar{B} \cap B(y_0, r)) \geq \frac{K}{C} w(\bar{B}).
\end{align*}

Thus
\[ 0 \leq q_1(x, y) \leq K \leq C \, w(B(y, 1))^{-1}. \]

We conclude by using the symmetry $q_1(x, y) = q_1(y, x)$.

Consider next a radial function $f$ satisfying (3)
\[ |f(x)| \lesssim (1 + \|x\|)^{-M - \kappa} \quad \forall \, x \in \mathbb{R}^N \]

with $M > N$ and $\kappa \geq 0$. Then the following estimate holds for the translates $f_t(x, y) = \tau_x f_t(-y)$ of $f_t(x) = t^{-N} f(t^{-1}x)$.

**Corollary 3.10.** There exists a constant $C > 0$ such that
\[ |f_t(x, y)| \leq C V(x, y, t)^{-1} \left( 1 + \frac{d(x, y)}{t} \right)^{-\kappa} \quad \forall \, t > 0, \forall \, x, y \in \mathbb{R}^N. \]

\(^3\) As usual, the symbol $\lesssim$ means that there exists a constant $C > 0$ such that $|f(x)| \leq C (1 + \|x\|)^{-M - \kappa}$. 
Proof. By scaling we can reduce to \( t = 1 \). By using (3.5), (3.6) and Proposition 3.9, we get
\[
|f_1(x, y)| \lesssim \int_{\mathbb{R}^N} (1 + A(x, y, \eta))^{-M} (1 + A(x, y, \eta))^{-\kappa} d\mu_\kappa(\eta)
\leq \int_{\mathbb{R}^N} (1 + A(x, y, \eta)^2)^{-M/2} (1 + d(x, y))^{-\kappa} d\mu_\kappa(\eta)
\leq CV(x, y, 1)^{-1}(1 + d(x, y))^{-\kappa}.
\]

Notice that the space of radial Schwartz functions \( f \) on \( \mathbb{R}^N \) identifies with the space of even Schwartz functions \( \tilde{f} \) on \( \mathbb{R} \), which is equipped with the norms
\[
\|\tilde{f}\|_{s,m} = \max_{0 \leq j \leq m} \sup_{x \in \mathbb{R}} (1 + |x|)^m \left| \left( \frac{d}{dx} \right)^j \tilde{f}(x) \right| \quad \forall \ m \in \mathbb{N}.
\]

Proposition 3.12. For every \( \kappa \geq 0 \), there exist \( C \geq 0 \) and \( m \in \mathbb{N} \) such that, for all even Schwartz functions \( \tilde{\psi}^{(1)}, \tilde{\psi}^{(2)} \) and for all even nonnegative integers \( \ell_1, \ell_2 \), the convolution kernel
\[
\Psi_{s,t}(x, y) = c_k^{-1} \int_{\mathbb{R}^N} (s \|\xi\|)^{\ell_1} \tilde{\psi}^{(1)}(s \|\xi\|) (t \|\xi\|)^{\ell_2} \tilde{\psi}^{(2)}(t \|\xi\|) E(x, i\xi) E(-y, i\xi) d\mu(\xi)
\]
satisfies
\[
|\Psi_{s,t}(x, y)| \leq C \|\tilde{\psi}^{(1)}\|_{s,\ell_1+\ell_2} \|\tilde{\psi}^{(2)}\|_{s,\ell_1+\ell_2} \times \min\left\{ \left( \frac{s}{t} \right)^{\ell_1}, \left( \frac{t}{s} \right)^{\ell_2} \right\} V(x, y, s + t)^{-1} \left( 1 + \frac{d(x, y)}{s + t} \right)^{-\kappa},
\]
for every \( s, t > 0 \) and for every \( x, y \in \mathbb{R}^N \).

Proof. By continuity of the inverse Dunkl transform in the Schwartz setting, there exists a positive even integer \( m \) and a constant \( C > 0 \) such that
\[
\sup_{z \in \mathbb{R}^N} (1 + \|z\|)^{M+\kappa} |F^{-1}f(z)| \leq C \|\tilde{f}\|_{s,m},
\]
for every even function \( \tilde{f} \in C^m(\mathbb{R}) \) with \( \|\tilde{f}\|_{s,m} < \infty \). Consider first the case \( 0 < s \leq t = 1 \). Then
\[
\| (s\xi)^{\ell_1} \tilde{\psi}^{(1)}(s\xi)^{\ell_2} \tilde{\psi}^{(2)}(\xi) \|_{s,m} \leq C \|\tilde{\psi}^{(1)}\|_{s,m} \|\tilde{\psi}^{(2)}\|_{s,\ell_1+\ell_2} s^{\ell_1}.
\]
According to Corollary 3.10, we deduce that
\[
|\Psi_{s,1}(x, y)| \leq CN s^{\ell_1} V(x, y, 1)^{-1} (1 + d(x, y))^{-\kappa}
\leq CN s^{\ell_1} V(x, y, s + 1)^{-1} \left( 1 + \frac{d(x, y)}{s + 1} \right)^{-\kappa},
\]
where \( N = \|\tilde{\psi}^{(1)}\|_{s,\ell_1+\ell_2} \|\tilde{\psi}^{(2)}\|_{s,\ell_1+\ell_2} \). In the case \( s \geq t > 0 \), we have similarly
\[
|\Psi_{1,t}(x, y)| \leq CN t^{\ell_2} V(x, y, 1 + t)^{-1} \left( 1 + \frac{d(x, y)}{1 + t} \right)^{-\kappa}.
\]
The general case is obtained by scaling.

4. Heat kernel and Dunkl kernel

Via the Dunkl transform, the heat semigroup \( H_t = e^{t\Delta} \) is given by
\[
H_t f(x) = \mathcal{F}^{-1}\left( e^{-t|x|^2} \mathcal{F} f(\xi) \right)(x).
\]
Alternately (see, e.g., [22])
\[
H_t f(x) = f * h_t(x) = \int_{\mathbb{R}^N} h_t(x,y) f(y) \, dw(y),
\]
where the heat kernel \( h_t(x,y) \) is a smooth positive radial convolution kernel. Specifically, for every \( t > 0 \) and for every \( x,y \in \mathbb{R}^N \),
\[
(4.1) \quad h_t(x,y) = c_k^{-1} (2t)^{-N/2} e^{-\frac{|x|^2 + |y|^2}{4t}} E\left( \frac{x}{\sqrt{2t}}, \frac{y}{\sqrt{2t}} \right) = \tau_x h_t(-y),
\]
where
\[
h_t(x) = \tilde{h}_t(||x||) = c_k^{-1} (2t)^{-N/2} e^{-\frac{|x|^2}{4t}}.
\]
In particular,
\[
h_t(x,y) = h_t(y,x) > 0,
\]
\[
\int_{\mathbb{R}^N} h_t(x,y) \, dw(y) = 1,
\]
\[
(4.2) \quad h_t(x,y) \leq c_k^{-1} (2t)^{-N/2} e^{-\frac{d(x,y)^2}{4t}}.
\]

**Upper heat kernel estimates.** We prove now Gaussian bounds for the heat kernel and its derivatives, in the spirit of spaces of homogeneous type, except that the metric \( ||x - y|| \) is replaced by the orbit distance \( d(x,y) \). In comparison with (4.2), the main difference lies in the factor \( t^{N/2} \), which is replaced by the volume of appropriate balls.

**Theorem 4.3.** (a) Time derivatives: for any nonnegative integer \( m \), there are constants \( C, c > 0 \) such that
\[
(4.4) \quad |\partial_t^m h_t(x,y)| \leq C t^{-m} V(x,y,\sqrt{t})^{-1} e^{-c d(x,y)^2/t},
\]
for every \( t > 0 \) and for every \( x,y \in \mathbb{R}^N \).
(b) Hölder bounds: for any nonnegative integer \( m \), there are constants \( C, c > 0 \) such that
\[
(4.5) \quad |\partial_t^m h_t(x,y) - \partial_t^m h_t(x,y')| \leq C t^{-m} \left( \frac{||y-y'||}{\sqrt{t}} \right) V(x,y,\sqrt{t})^{-1} e^{-c d(x,y)^2/t},
\]
for every \( t > 0 \) and for every \( x,y,y' \in \mathbb{R}^N \) such that \( ||y-y'|| < \sqrt{t} \).
(c) Dunkl derivative: for any \( \xi \in \mathbb{R}^N \) and for any nonnegative integer \( m \), there are constants \( C, c > 0 \) such that
\[
(4.6) \quad \left| T_{\xi,x} \partial_t^m h_t(x,y) \right| \leq C t^{-m-1/2} V(x,y,\sqrt{t})^{-1} e^{-c d(x,y)^2/t},
\]
for all \( t > 0 \) and \( x,y \in \mathbb{R}^N \).
(d) Mixed derivatives: for any nonnegative integer $m$ and for any multi-indices $\alpha, \beta$, there are constants $C, c > 0$ such that, for every $t > 0$ and for every $x, y \in \mathbb{R}^N$,

$$
\left| \partial_t^m \partial_x^\alpha \partial_y^\beta h_t(x, y) \right| \leq C t^{-m - \frac{|\alpha|}{2} - \frac{|\beta|}{2}} V(x, y, \sqrt{t})^{-1} e^{-cd(x, y)^2/t},
$$

for every $t > 0$ and for every $x, y \in \mathbb{R}^N$.

Proof. The proof relies on the expression

$$
h_t(x, y) = \int_{\mathbb{R}^N} \tilde{h}_t(A(x, y, \eta)) d\mu_x(\eta)
$$

and on the properties of $A(x, y, \eta)$.

(a) Consider first the case $m = 0$. By scaling we can reduce to $t = 1$. On the one hand, we use (3.6) to estimate

$$
c_k 2^{N/2} h_1(x, y) = \int_{\mathbb{R}^N} e^{-A(x, y, \eta)^2/8} e^{-A(x, y, \eta)^2/8} d\mu_x(\eta)
\leq e^{-d(x, y)^2/8} \int_{\mathbb{R}^N} e^{-A(x, y, \eta)^2/8} d\mu_x(\eta).
$$

On the other hand, it follows from Proposition 3.9 and Corollary 3.10 that

$$
\int_{\mathbb{R}^N} e^{-c A(x, y, \eta)^2} d\mu_x(\eta) \lesssim V(x, y, 1)^{-1},
$$

for any fixed $c > 0$. Hence

$$
h_1(x, y) \lesssim V(x, y, 1)^{-1} e^{-d(x, y)^2/8}.
$$

Consider next the case $m > 0$. Observe that $\partial_t^m \tilde{h}_t(x)$ is equal to $t^{-m} e^{-x^2/4t}$ times a polynomial in $\frac{x^2}{t}$, hence

$$
\left| \partial_t^m \tilde{h}_t(x) \right| \leq C_m t^{-m} \tilde{h}_{2t}(x).
$$

By differentiating (4.8) and by using (4.9), we deduce that

$$
\left| \partial_t^m h_t(x, y) \right| \leq C_m t^{-m} h_{2t}(x, y).
$$

We conclude by using the case $m = 0$.

(b) Observe now that $\tilde{h}_t(x) = \partial_x \partial_t^m h_t(x)$ is equal to $\frac{x}{t^{m+1}} e^{-x^2/4t}$ times a polynomial in $\frac{x^2}{t}$, hence

$$
\left| \tilde{h}_t(x) \right| \leq C_m t^{-m-1/2} \tilde{h}_{2t}(x).
$$
By differentiating (4.8) and by using (3.8) and (4.4), we estimate
\[
|\partial_t^m h_t(x, y) - \partial_t^m h_t(x, y')| = \left| \int_{\mathbb{R}^N} \left\{ \partial_t^m \tilde{h}_t(A(x, y, \eta)) - \partial_t^m \tilde{h}_t(A(x, y', \eta)) \right\} d\mu_\eta(\eta) \right|
\]
\[
= \left| \int_{\mathbb{R}^N} \int_0^1 \frac{\partial}{\partial s} \partial_t^m \tilde{h}_t(A(x, y + s(y - y'), \eta)) \, ds \, d\mu_\eta(\eta) \right|
\]
\[
\leq \|y - y'\| \int_0^1 \int_{\mathbb{R}^N} \left| \tilde{h}_t(A(x, y, \eta)) \right| \, d\mu_\eta(\eta) \, ds
\]
\[
\leq C_m \left( \frac{\|y - y'\|}{\sqrt{t}} \right) \int_0^1 h_{2t}(x, y_s) \, ds
\]
\[
\leq C_m' \left( \frac{\|y - y'\|}{\sqrt{t}} \right) \int_0^1 V(x, y_s, \sqrt{2t}) \, e^{-c \frac{d(x, y_s)^2}{2}} \, ds .
\]
In order to conclude, notice that
\[
(4.11) \quad V(x, y_s, \sqrt{2t}) \sim V(x, y, \sqrt{t})
\]
under the assumption \(\|y - y'\| < \sqrt{t}\) and let us show that, for every \(c > 0\), there exists \(C \geq 1\) such that
\[
(4.12) \quad C^{-1} e^{-\frac{3}{2} c \frac{d(x, y)^2}{t}} \leq e^{-c \frac{d(x, y_s)^2}{t}} \leq C e^{-\frac{1}{2} c \frac{d(x, y)^2}{t}} .
\]
As long as \(d(x, y) = O(\sqrt{t})\), all expressions in (4.12) are indeed comparable to 1. On the other hand, if \(d(x, y) \geq \sqrt{32t}\), then
\[
|d(x, y)^2 - d(x, y_s)^2| = |d(x, y) - d(x, y_s)| \{d(x, y) + d(x, y_s)\}
\]
\[
\leq \|y - y_s\| \left\{ 2 d(x, y) + \|y - y_s\| \right\} \leq \sqrt{8t} \left\{ 2 d(x, y) + \sqrt{2t} \right\}
\]
\[
\leq \sqrt{8t} d(x, y) + 2t \leq \frac{1}{2} d(x, y)^2 + 2t .
\]
Hence
\[
\frac{1}{2} d(x, y)^2/t - 2 \leq d(x, y_s)^2/t \leq \frac{3}{2} d(x, y)^2/t + 2 .
\]
(c) By symmetry, we can replace \(T_{\xi, x}\) by \(T_{\xi, y}\). Consider first the contribution of the directional derivative in \(T_{\xi, y}\). By differentiating (4.8) and by using (4.10) and (4.4), we estimate as above
\[
|\partial_{\xi, y} \partial_t^m h_t(x, y)| \leq \|\xi\| \int_{\mathbb{R}^N} \left| \tilde{h}_t(A(x, y, \eta)) \right| \, d\mu_\eta(\eta)
\]
\[
\leq C t^{-m-1/2} h_{2t}(x, y)
\]
\[
\leq C t^{-m-1/2} V(x, y, \sqrt{t})^{-1} e^{-c d(x, y)^2/t} .
\]
Consider next the contributions
\[
(4.13) \quad \frac{\partial_t^m h_t(x, y) - \partial_t^m h_t(x, \sigma_\alpha(y))}{(\alpha, y)}
\]
of the difference operators in $T_{\xi,y}$. If $|\langle \alpha, y \rangle| > \sqrt{t/2}$, we use (4.4) and estimate separately each term in (4.13). If $|\langle \alpha, y \rangle| \leq \sqrt{t/2}$, we estimate again
\[
\left| \frac{\partial^m h_t(x, y) - \partial^m h_t(x, \sigma \alpha(y))}{\langle \alpha, y \rangle} \right| \leq \sqrt{2} \int_{\mathbb{R}^N} \int_0^1 |\tilde{h}_t(A(x, y_s, \eta))| ds d\mu_x(\eta)
\leq C t^{-m/2} \int_0^1 h_{2t}(x, y_s) ds
\leq C t^{-m/2} \int_0^1 V(x, y_s, \sqrt{2t})^{-1} e^{-c \frac{d(x, y_s)^2}{2t}} ds
\leq C t^{-m/2} V(x, y, \sqrt{t})^{-1} e^{-c \frac{d(x, y)^2}{2t}}.
\]
In the last step we have used (4.11) and (4.12), which hold as $\|y_s - y\| \leq \sqrt{t}$.

(d) This time, we use (3.7) to estimate
\[
|\partial^m \tilde{h}_t(A(x, y, \eta))| \leq C_{m,\beta} t^{-m-|\beta|} \tilde{h}_t(A(x, y, \eta)).
\]
Firstly, by differentiating (4.8) and by using (4.14), we obtain
\[
|\partial^m \partial^\beta h_t(x, y)| \leq C_{m,\beta} t^{-m-|\beta|/2} h_{2t}(x, y).
\]
Secondly, by differentiating
\[
h_t(x, y) = \int_{\mathbb{R}^N} h_{t/2}(x, z) h_{t/2}(z, y) dw(z),
\]
by using (4.15) and by symmetry, we get
\[
|\partial^m \partial^\beta \partial^\gamma h_t(x, y)| \leq C_{m,\alpha,\beta} t^{-m-|\alpha|/2 - |\beta|} h_{2t}(x, y).
\]
We conclude by using (4.4).

\[\square\]

**Lower heat kernel estimates.** We begin with an auxiliary result.

**Lemma 4.16.** Let $\tilde{f}$ be a smooth bump function on $\mathbb{R}$ such that $0 \leq \tilde{f} \leq 1$, $\tilde{f}(x) = 1$ if $|x| \leq \frac{1}{2}$ and $\tilde{f}(x) = 0$ if $|x| \geq 1$. Set as usual
\[
f(x) = \tilde{f}(|x|) \quad \text{and} \quad f(x, y) = \tau_x f(-y).
\]
Then $0 \leq f(x, y) \leq 1$ and $f(x, y) = 0$ if $d(x, y) \geq 1$. Moreover there exists a positive constant $c_1$ such that
\[
\sup_{y \in \mathcal{O}(B(x, 1))} f(x, y) \geq \frac{c_1}{w(B(x, 1))}
\]
for every $x \in \mathbb{R}^N$.

**Proof.** All claims follow from (3.5) and (3.6). Let us prove the last one. On the one hand, by translation invariance,
\[
\int_{\mathbb{R}^N} f(x, y) dw(y) = \int_{\mathbb{R}^N} f(y) dw(y) \geq w(B(0, 1/2)).
\]
On the other hand,
\[ \int_{\mathbb{R}^N} f(x, y) \, dw(y) = \int_{O(B(x, 1))} f(x, y) \, dw(y) \leq |G| \, w(B(x, 1)) \sup_{y \in O(B(x, 1))} f(x, y). \]
This proves (4.17) with \( c_1 = \frac{w(B(0, 1/2))}{|G|} \). \( \square \)

**Proposition 4.18.** There exist positive constants \( c_2 \) and \( \varepsilon \) such that
\[ h_t(x, y) \geq \frac{c_2}{w(B(x, \sqrt{t}))} \]
for every \( t > 0 \) and \( x, y \in \mathbb{R}^N \) satisfying \( \|x - y\| \leq \varepsilon \sqrt{t} \).

**Proof.** By scaling it suffices to prove the proposition for \( t = 2 \). According to Lemma 4.16, applied to \( \tilde{h}_1 \gtrsim \tilde{f} \) (4), there exists \( c_3 > 0 \) and, for every \( x \in \mathbb{R}^N \), there exists \( y(x) \in O(B(x, 1)) \) such that
\[ h_1(x, y(x)) \geq c_3 w(B(x, 1))^{-1}. \]
This estimate holds true around \( y(x) \), according to (4.5), Specifically, there exists \( 0 < \varepsilon < 1 \) (independent of \( x \)) such that
\[ h_1(x, y) \geq \frac{\varepsilon}{t} \, w(B(x, 1))^{-1} \quad \forall \, y \in B(y(x), \varepsilon). \]
By using the semigroup property and the symmetry of the heat kernel, we deduce that
\[ h_2(x, x) = \int h_1(x, y) \, h(y, x) \, dw(y) \]
\[ \geq \int_{B(y(x), \varepsilon)} h_1(x, y)^2 \, dw(y) \]
\[ \geq w(B(y(x), \varepsilon)) \left( \frac{\varepsilon}{t} \right)^2 \, w(B(x, 1))^{-2}. \]
By using the fact that the balls \( B(y(x), \varepsilon), B(x, 1), B(x, \sqrt{2}) \) have comparable volumes and by using again (4.5), we conclude that
\[ h_2(x, y) \geq c_4 \, w(B(x, \sqrt{2}))^{-1} \]
for all \( x, y \in \mathbb{R}^N \) sufficiently close. \( \square \)

A standard argument, which we include for the reader’s convenience, allows us to deduce from such a near on diagonal estimate the following global lower Gaussian bound.

**Theorem 4.19.** There exist positive constants \( C \) and \( c \) such that
\[ h_t(x, y) \geq \frac{C}{\min \{w(B(x, \sqrt{t})), w(B(y, \sqrt{t}))\}} \, e^{-c \|x - y\|^2/t} \]
for every \( t > 0 \) and for every \( x, y \in \mathbb{R}^N \).

\(^4\) As usual, the symbol \( \gtrsim \) means that there exists a constant \( C > 0 \) such that \( \tilde{h}_1 \gtrsim C \tilde{f} \).
Proof. We resume the notation of Proposition 4.18. Assume that $\|x - y\|^2 / t \geq 1$ and set $n = \lceil 4\|x - y\|^2/(\varepsilon^2 t) \rceil \geq 4$. Let $x_i = x + i(y - x)/n$ ($i = 0, \ldots, n$), so that $x_0 = x$, $x_n = y$, and $\|x_{i+1} - x_i\| = \|x - y\|/n$. Consider the balls $B_i = B(x_i, \varepsilon \sqrt{t/n})$ and observe that

$$\|y_{i+1} - y_i\| \leq \|y_i - x_i\| + \|x_i - x_{i+1}\| + \|x_{i+1} - y_i + 1\| < \frac{\varepsilon}{4} \sqrt{\frac{t}{n}} + \frac{\varepsilon}{2} \sqrt{\frac{t}{n}} + \frac{\varepsilon}{4} \sqrt{\frac{t}{n}} = \varepsilon \sqrt{\frac{t}{n}}$$

if $y_i \in B_i$ and $y_{i+1} \in B_{i+1}$. By using the semigroup property, Proposition 4.18 and the behavior of the ball volume, we estimate

$$h_t(x, y) = \int_{\mathbb{R}^N} \cdots \int_{\mathbb{R}^N} h_{t/n}(x, y_1)h_{t/n}(y_1, y_2) \cdots h_{t/n}(y_{n-1}, y) \, dw(y_1) \cdots dw(y_{n-1})$$

$$\geq c_2^{n-1} \int_{B_1} \cdots \int_{B_{n-1}} w(B(x, \sqrt{t/n}))^{-1} \cdots w(B(y_{n-1}, \sqrt{t/n}))^{-1} \, dw(y_1) \cdots dw(y_{n-1})$$

$$\geq c_3^{n-1} w(B(x, \sqrt{t/n}))^{-1} \frac{w(B_1) \cdots w(B_{n-1})}{w(B(x_1, \sqrt{t/n}) \cdots w(B(x_{n-1}, \sqrt{t/n}))}$$

$$\geq c_5^{n-1} w(B(x, \sqrt{t}))^{-1} = c_5^{-1} w(B(x, \sqrt{t}))^{-1} e^{-n \ln c_5^{-1}} \geq C w(B(x, \sqrt{t}))^{-1} e^{-\frac{\|x - y\|^2}{1}}.$$  

We conclude by symmetry. □

By combining (4.4) and (4.20), we obtain in particular the following near on diagonal estimates. Notice that the ball volumes $w(B(x, \sqrt{t}))$ and $w(B(y, \sqrt{t}))$ are comparable under the assumptions below.

Corollary 4.21. For every $c > 0$, there exists $C > 0$ such that

$$\frac{C}{w(B(x, \sqrt{t}))} \leq h_t(x, y) \leq \frac{C}{w(B(x, \sqrt{t}))}$$

for every $t > 0$ and $x, y \in \mathbb{R}^N$ such that $\|x - y\| \leq c \sqrt{t}$.

Estimates of the Dunkl kernel. According to (4.1), the heat kernel estimates (4.4) and (4.20) imply the following results, which partially improve upon known estimates for the Dunkl kernel. Notice that $x$ can be replaced by $y$ in the ball volumes below.

Corollary 4.22. There are constants $c \geq 1$ and $C \geq 1$ such that

$$\frac{C^{-1}}{w(B(x, 1))} e^{-\frac{c}{2} \|x - y\|^2} \leq E(x, y) \leq \frac{C}{w(B(x, 1))} e^{-\frac{c}{2} \|x - y\|^2}$$

for all $x, y \in \mathbb{R}^N$. In particular,

- for every $\varepsilon > 0$, there exist $C \geq 1$ such that
  $$\frac{C^{-1}}{w(B(x, 1))} e^{-\frac{c}{2} \|x - y\|^2} \leq E(x, y) \leq \frac{C}{w(B(x, 1))} e^{-\frac{c}{2} \|x - y\|^2}$$

for all $x, y \in \mathbb{R}^N$ satisfying $\|x - y\| < \varepsilon$;

- there exist $c > 0$ and $C > 0$ such that
  $$E(\lambda x, y) \geq \frac{C}{w(B(\sqrt{\lambda} x, 1))} e^{\lambda (1 - c) \|x - y\|^2}$$
for all $\lambda \geq 1$ and for all $x, y \in \mathbb{R}^N$ with $\|x\| = \|y\| = 1$.

5. Poisson kernel in the Dunkl setting

The Poisson semigroup $P_t = e^{-t\sqrt{-\Delta}}$ is subordinated to the heat semigroup $H_t = e^{t\Delta}$ by (2.2) and correspondingly for their integral kernels

$$p_t(x, y) = \pi^{-1/2} \int_0^\infty e^{-u} h_{t/4u}^2(x, y) \frac{du}{\sqrt{u}}.$$  

This subordination formula enables us to transfer properties of the heat kernel $h_t(x, y)$ to the Poisson kernel $p_t(x, y)$. For instance,

$$p_t(x, y) = p_t(y, x) > 0,$$

$$\int_{\mathbb{R}^N} p_t(x, y) \, dw(y) = 1,$$

where

$$p_t(x, y) = \tau_x p_t(-y),$$

and

$$p_t(x) = \tilde{p}_t(\|x\|) = c'_k \left( t^2 + \|x\|^2 \right)^{-\frac{N+1}{2}}$$

and

$$c'_k = \frac{2^{N/2} \Gamma(\frac{N+1}{2})}{\sqrt{\pi e_k}} > 0.$$

The following global bounds hold for the Poisson kernel and its derivatives.

**Proposition 5.4.** (a) Upper and lower bounds: there is a constant $C \geq 1$ such that

$$\frac{C^{-1}}{V(x, y, t + \|x - y\|)} \leq p_t(x, y) \leq \frac{C}{V(x, y, t + d(x, y))}$$

for every $t > 0$ and for every $x, y \in \mathbb{R}^N$.

(b) Dunkl gradient: for every $\xi \in \mathbb{R}^N$, there is a constant $C > 0$ such that

$$|T_{\xi,y} p_t(x, y)| \leq \frac{C}{V(x, y, t + d(x, y))} \frac{1}{t + d(x, y)}$$

for all $t > 0$ and $x, y \in \mathbb{R}^N$.

(c) Mixed derivatives: for any nonnegative integer $m$ and for any multi-index $\beta$, there is a constant $C \geq 0$ such that, for every $t > 0$ and for every $x, y \in \mathbb{R}^N$,

$$\left| \partial_x^m \partial_y^\beta p_t(x, y) \right| \leq C p_t(x, y) (t + d(x, y))^{-m-|\beta|} \times \left\{ \begin{array}{ll} 1 & \text{if } m = 0, \\ 1 + \frac{d(x, y)}{t} & \text{if } m > 0. \end{array} \right.$$  

Moreover, for any nonnegative integer $m$ and for any multi-indices $\beta, \beta'$, there is a constant $C \geq 0$ such that, for every $t > 0$ and for every $x, y \in \mathbb{R}^N$,

$$\left| \partial_x^m \partial_y^\beta \partial_y^\beta' p_t(x, y) \right| \leq C t^{-m-|\beta|-|\beta'|} p_t(x, y).$$

Notice that, by symmetry, (5.6) holds also with $T_{\xi,x}$ instead of $T_{\xi,y}$.
Proof. (a) The Poisson kernel bounds (5.5) are obtained by inserting the heat kernel bounds (4.4) and (4.20) in the subordination formula (5.1). For a detailed proof we refer the reader to [11, Proposition 6].

(b) The Dunkl gradient estimate (5.6) is deduced similarly from (4.6).

(c) The estimate (5.7) is proved directly. As \((t, x) \mapsto (t^2 + x^2)^{-(N+1)/2}\) is a homogeneous symbol of order \(-N-1\) on \(\mathbb{R}^2\), we have

\[
\begin{align*}
|\partial^\beta_x \tilde{p}_t(x)| &\leq C_\beta (t + |x|)^{-\beta} \tilde{p}_t(x) \\
|\partial^m_t \partial^\beta_x \tilde{p}_t(x)| &\leq C_{m,\beta} t^{-1} (t + |x|)^{1-m-\beta} \tilde{p}_t(x)
\end{align*}
\]

for every positive integer \(m\) and for every nonnegative integer \(\beta\). By using (3.5), (3.6), (5.2), (5.3) and (5.9), we estimate

\[
|\partial^\beta_y p_t(x, y)| \leq \int_{\mathbb{R}^N} |\partial^\beta_x \tilde{p}_t(A(x, y, \eta))| \, d\mu_x(\eta)
\]

\[
\leq C_\beta \int_{\mathbb{R}^N} \left( t + A(x, y, \eta) \right)^{-|\beta|} \tilde{p}_t(A(x, y, \eta)) \, d\mu_x(\eta)
\]

\[
\leq C_\beta \left( t + d(x, y) \right)^{-|\beta|} p_t(x, y)
\]

and similarly

\[
|\partial^m_t \partial^\beta_x p_t(x, y)| \leq C_{m,\beta} t^{-1} \left( t + d(x, y) \right)^{1-m-|\beta|} p_t(x, y)
\]

for every positive integer \(m\). Finally (5.8) is deduced from (5.7) by using the semigroup property. More precisely, by differentiating

\[
p_t(x, y) = \int_{\mathbb{R}^N} p_{t/2}(x, z) \, p_{t/2}(z, y) \, dw(z),
\]

by using (5.7) and by symmetry, we obtain

\[
|\partial^m_t \partial^\beta_x \partial^\gamma_y p_t(x, y)| \lesssim t^{-m-|\beta|-|\beta'|} \int_{\mathbb{R}^N} p_{t/2}(x, z) \, p_{t/2}(z, y) \, dw(z) = t^{-m-|\beta|-|\beta'|} p_t(x, y).
\]

Notice the following straightforward consequence of the upper bound in (5.5):

\[
(5.10) \quad \mathcal{M}_P f(x) \lesssim \sum_{\sigma \in G} \mathcal{M}_{HL} f(\sigma(x)),
\]

where \(\mathcal{M}_{HL}\) denotes the Hardy-Littlewood maximal function on the space of homogeneous type \((\mathbb{R}^N, \|x-y\|, dw)\). Likewise, (4.4) yields

\[
\mathcal{M}_H f(x) \lesssim \sum_{\sigma \in G} \mathcal{M}_{HL} f(\sigma(x)).
\]

Observe that the Poisson kernel is an approximation of the identity in the following sense.
Proposition 5.11. Given any compact subset $K \subset \mathbb{R}^N$, any $r > 0$ and any $\varepsilon > 0$, there exists $t_0 = t_0(K, r, \varepsilon) > 0$ such that, for every $0 < t < t_0$ and for every $x \in K$,

$$\int_{|x-y| > r} p_t(x, y) \, dw(y) < \varepsilon.$$  

Proof. Let $K$ be a compact subset of $\mathbb{R}^N$ and let $r, \varepsilon > 0$. Fix $x_0 \in K$ and consider $f \in C_c^\infty(\mathbb{R}^N)$ such that $0 \leq f \leq 1$, $f = 1$ on $B(x_0, r/4)$ and supp $f \subset B(x_0, r/2)$. By the inversion formula,

$$f(x) - P_t f(x) = c_k^{-1} \int_{\mathbb{R}^N} (1 - e^{-t||\xi||}) E(i\xi, x) \mathcal{F} f(\xi) \, d\xi,$$

hence

(5.12)  

$$|f(x) - P_t f(x)| \leq c_k^{-1} \int_{\mathbb{R}^N} (1 - e^{-t||\xi||}) |\mathcal{F} f(\xi)| \, d\xi.$$  

As $\mathcal{F} f \in \mathcal{S}(\mathbb{R}^N)$, (5.12) implies that there is $t_0 = t_0(x_0, r, \varepsilon) > 0$ such that

$$\sup_{x \in \mathbb{R}^N} |f(x) - P_t f(x)| < \varepsilon \quad \forall 0 < t < t_0.$$  

In particular, for every $0 < t < t_0$ and for every $x \in B(x_0, r/4)$, we have

$$0 \leq \int_{|x-y| > r} p_t(x, y) \, dw(y) = 1 - \int_{|x-y| \leq r} p_t(x, y) \, dw(y) \leq f(x) - \int_{|x-y| \leq r} p_t(x, y) f(y) \, dw(y) \leq |f(x) - P_t f(x)| < \varepsilon.$$  

A straightforward compactness argument allows us to conclude. \hfill \Box

The following results follow from (5.5), (5.10), and Proposition 5.11.

Corollary 5.13. Let $f$ be a bounded continuous function on $\mathbb{R}^N$. Then its Poisson integral $u(t, x) = P_t f(x)$ is also bounded and continuous on $[0, \infty) \times \mathbb{R}^N$.

Corollary 5.14. Let $f \in L^p(dw)$ with $1 \leq p \leq \infty$. Then for almost every $x \in \mathbb{R}^N$

$$\lim_{t \to 0} \sup_{\|y-x\| < t} |P_t f(y) - f(x)| = 0.$$  

Remark 5.15. The assertion of Proposition 5.11 remains valid with the same proof if $p_t(x, y)$ is replaced by $\Phi_t(x, y) = \tau_x \Phi_t(-y)$, where $\Phi \in \mathcal{S}(\mathbb{R}^N)$ is radial, nonnegative, and $\int \Phi(x) \, dw(x) = 1$.

6. Conjugate harmonic functions - subharmonicity

For $\sigma \in G$ let $f^\sigma(x) = f(\sigma(x))$. It is easy to check that

(6.1)  

$$T_\xi f^\sigma(x) = (T_{\sigma \xi} f)^\sigma(x), \quad \sigma \in G, \ x, \xi \in \mathbb{R}^N,$$

$$(\Delta f^\sigma)(x) = (\Delta f)^\sigma(x).$$  

Let $\{\sigma_{ij}\}_{i,j=1}^N$ denote the matrix of $\sigma \in G$ written in the canonical basis $e_1, \ldots, e_N$ of $\mathbb{R}^N$. Clearly, $\{\sigma_{ij}\} \in O(N)$. 

Lemma 6.2. Assume that \( u(x_0, x) = (u_0(x_0, x), u_1(x_0, x), \ldots, u_N(x_0, x)) \) satisfies the Cauchy-Riemann equations (2.4). For \( \sigma \in G \) set

\[
(6.3) \quad u_{\sigma,0}(x_0, x) = u_0(x_0, \sigma(x)), \quad u_{\sigma,j}(x_0, x) = \sum_{i=1}^N \sigma_{ij} u_i(x_0, \sigma(x)), \; j = 1, 2, \ldots, N.
\]

Then \( u_{\sigma}(x_0, x) = (u_{\sigma,0}(x_0, x), u_{\sigma,1}(x_0, x), \ldots, u_{\sigma,N}(x_0, x)) \) satisfies the Cauchy-Riemann equations. Moreover,

\[
(6.4) \quad |u_{\sigma}(x_0, x)| = |u(x_0, \sigma(x))|.
\]

Proof. Let \( 1 \leq k, j \leq N \). Then

\[
(6.5) \quad T_k u_{\sigma,j}(x_0, x) = \sum_{i=1}^N \sigma_{ij} T_k (u_i(x_0, \sigma(\cdot)))(x) = \sum_{i=1}^N \sigma_{ij} \sum_{\ell=1}^N \sigma_{\ell k} (T_{\ell} u_i)(x_0, \sigma(x)),
\]

and, similarly,

\[
(6.6) \quad T_j u_{\sigma,k}(x_0, x) = \sum_{i=1}^N \sigma_{ik} \sum_{\ell=1}^N \sigma_{\ell j} (T_{\ell} u_i)(x_0, \sigma(x)).
\]

Recall that \( T_{\ell} u_i = T_i u_{\ell} \). Hence, (6.6) becomes

\[
(6.7) \quad T_j u_{\sigma,k}(x_0, x) = \sum_{i=1}^N \sigma_{ik} \sum_{\ell=1}^N \sigma_{\ell j} (T_{\ell} u_i)(x_0, \sigma(x)).
\]

Now we see that (6.5) and (6.7) are equal. The proof that \( T_k u_{\sigma,0} = T_0 u_{\sigma,k} \) is straightforward. The second equality of (2.4) follows directly from (6.7) and the fact that \( \sigma^{-1} = \sigma^* \).

Since \( \{\sigma_{ij}\} \in O(N) \),

\[
(6.8) \quad |u_{\sigma,0}(x_0, x)|^2 + \sum_{j=1}^N |u_{\sigma,j}(x_0, x)|^2 = |u_0(x_0, \sigma(x))|^2 + \sum_{j=1}^N \sum_{i=1}^N |\sigma_{ij} u_i(x_0, \sigma(x))|^2
\]

\[
= |u_0(x_0, \sigma(x))|^2 + \sum_{i=1}^N |u_i(x_0, \sigma(x))|^2,
\]

which proves (6.4). \( \square \)

Let

\[
(6.9) \quad F(t, x) = \{ u_{\sigma}(t, x) \}_{\sigma \in G}.
\]

We shall always assume that \( u \) and \( u_{\sigma} \) are related by (6.3). Then, by (6.4),

\[
|F(x_0, x)|^2 = \sum_{\sigma \in G} \sum_{t=0}^N |u_{\sigma,t}(x_0, x)|^2 = \sum_{\sigma \in G} |u_{\sigma}(x_0, x)|^2 = \sum_{\sigma \in G} |u(x_0, \sigma(x))|^2.
\]

Observe that \( |F(x_0, x)| = |F(x_0, \sigma(x))| \) for every \( \sigma \in G \).

Consequently, for every \( \alpha \in R \),
\[
\sum_{\sigma \in G} \sum_{t=0}^{N} \left( u_{\sigma,t}(x_0, x) - u_{\sigma,t}(x_0, \sigma(x)) \right) \cdot u_{\sigma,t}(x_0, x) = \frac{1}{2} \sum_{\sigma \in G} \sum_{t=0}^{N} \left| u_{\sigma,t}(x_0, x) - u_{\sigma,t}(x_0, \sigma(x)) \right|^2.
\]

We shall need the following auxiliary lemma.

**Lemma 6.11.** For every \(\varepsilon > 0\) there is \(\delta > 0\) such that for every matrix \(A = \{a_{ij}\}_{i,j=0}^{N}\) with real entries \(a_{ij}\) one has

\[
\|A\|^2 \leq \varepsilon \left( (\text{tr}A)^2 + \sum_{i<j} (a_{ij} - a_{ji})^2 \right) + (1 - \delta) \|A\|_{\text{HS}}^2,
\]

where \(\|A\|_{\text{HS}}\) denotes the Hilbert-Schmidt norm of \(A\).

**Proof.** The lemma was proved in [9]. For the convenience of the reader we present a short proof. The inequality is known for trace zero symmetric \(A\) (see Stein and Weiss [26, Lemma 2.2]). By homogeneity we may assume that \(\|A\|_{\text{HS}} = 1\). Assume that the inequality does not hold. Then there is \(\varepsilon > 0\) such that for every \(n > 0\) there is \(A_n = \{a_{ij}^{(n)}\}_{i,j=0}^{N}\), \(\|A_n\|_{\text{HS}} = 1\) such that

\[
\|A_n\|^2 > \varepsilon \left( (\text{tr}A_k)^2 + \sum_{i<j} (a_{ij}^{(n)} - a_{ji}^{(n)})^2 \right) + \left( 1 - \frac{1}{n} \right) \|A_n\|_{\text{HS}}^2.
\]

Thus there is a subsequence \(n_s\) such that \(A_{n_s} \rightarrow A\), \(\|A\|_{\text{HS}} = 1\) and

\[
\|A\|^2 \geq \varepsilon \left( (\text{tr}A)^2 + \sum_{i<j} (a_{ij} - a_{ji})^2 \right) + \|A\|_{\text{HS}}^2.
\]

But then \(A = A^*\) and \(\text{tr}A = 0\), and so, \(\|A\|^2 \geq \|A\|_{\text{HS}}^2\). This contradicts the already known inequality. \(\square\)

We now state and prove the main theorem of Section 6, which is the analog in the Dunkl setting of a Euclidean subharmonicity property (see [24, Chapter VII, Section 3.1]) and which was proved in the product case in [9, Proposition 4.1]. Recall (2.3) that \(\mathcal{L} = T_0^2 + \Delta\).

**Theorem 6.12.** There is an exponent \(0 < q < 1\) which depends on \(k\) such that if \(u = (u_0, u_1, \ldots, u_N) \in C^2\) satisfies the Cauchy-Riemann equations (2.4), then the function \(|F|^q\) is \(\mathcal{L}\)-subharmonic, that is, \(\mathcal{L}(|F|^q)(t, x) \geq 0\) on the set where \(|F| > 0\).

**Proof.** Observe that \(|F|^q\) is \(C^2\) on the set where \(|F| > 0\). Let \(\cdot\) denote the inner product in \(\mathbb{R}^{(N+1):G}\). For \(j = 0, 1, \ldots, N\), we have

\[
\partial_{e_j} |F|^q = q |F|^{q-2}\left( (\partial_{e_j} F) \cdot F \right)
\]

\[
\partial_{e_j}^2 |F|^q = q(q-2) |F|^{q-4}\left( (\partial_{e_j} F) \cdot F \right)^2 + q |F|^{q-2}\left( (\partial_{e_j}^2 F) \cdot F + |\partial_{e_j} F|^2 \right).
\]
Recall that $|F(x_0, x)| = |F(x_0, \sigma(x))|$. Hence,

$$
\mathcal{L}|F|^q = q(q - 2)|F|^{q-4}\left\{ \left( \sum_{j=0}^{N} \left( (\partial_{x_j} F) \cdot F \right) \right)^2 \right\}
$$

(6.13)

$$
+ q|F|^{q-2}\left\{ \left( \sum_{j=0}^{N} \partial_{x_j} F + 2 \sum_{\alpha \in R^+} \frac{k(\alpha)}{\langle \alpha, x \rangle} \partial_{\alpha} F \right) \cdot F + \sum_{j=0}^{N} |\partial_{x_j} F|^2 \right\}.
$$

Since $T_j T_{\ell} = T_{\ell} T_j$, we conclude from (2.4) applied to $u_\sigma$ that for $\ell = 0, 1, \ldots, N$, we have

$$
\sum_{j=0}^{N} \partial_{x_j}^2 u_{\sigma, \ell}(x_0, x) + 2 \sum_{\alpha \in R^+} \frac{k(\alpha)}{\langle \alpha, x \rangle} \partial_{\alpha} u_{\sigma, \ell}(x_0, x) = \sum_{\alpha \in R^+} k(\alpha) \|\alpha\|^2 \frac{u_{\sigma, \ell}(x_0, x) - u_{\sigma, \ell}(x_0, \sigma(\alpha))}{\langle \alpha, x \rangle^2}.
$$

Thus,

$$
\left( \sum_{j=0}^{N} \partial_{x_j}^2 F + 2 \sum_{\alpha \in R^+} \frac{k(\alpha)}{\langle \alpha, x \rangle} \partial_{\alpha} F \right) \cdot F
$$

$$
= \sum_{\sigma \in G} \sum_{\ell=0}^{N} \left( \sum_{j=0}^{N} \partial_{x_j}^2 u_{\sigma, \ell}(x_0, x) + 2 \sum_{\alpha \in R^+} \frac{k(\alpha)}{\langle \alpha, x \rangle} \partial_{\alpha} u_{\sigma, \ell}(x_0, x) \right) u_{\sigma, \ell}(x_0, x)
$$

$$
= \sum_{\alpha \in R^+} \sum_{\sigma \in G} \sum_{\ell=0}^{N} \frac{k(\alpha) \|\alpha\|^2}{\langle \alpha, x \rangle^2} \sum_{\sigma \in G} \left( u_{\sigma, \ell}(x_0, x) - u_{\sigma, \ell}(x_0, \sigma(\alpha)) \right) u_{\sigma, \ell}(x_0, x)
$$

$$
= \frac{1}{2} \sum_{\alpha \in R^+} \frac{k(\alpha) \|\alpha\|^2}{\langle \alpha, x \rangle^2} \sum_{\sigma \in G} \sum_{\ell=0}^{N} \left( u_{\sigma, \ell}(x_0, x) - u_{\sigma, \ell}(x_0, \sigma(\alpha)) \right)^2.
$$

Thanks to (6.13) and (6.14), it suffices to prove that there is $0 < q < 1$ such that

$$
(2 - q) \sum_{j=0}^{N} \left( (\partial_{x_j} F(x_0, x)) \cdot F(x_0, x) \right)^2
$$

(6.15)

$$
\leq \frac{1}{2} |F(x_0, x)|^2 \sum_{\sigma \in G} \sum_{\ell=0}^{N} \sum_{\alpha \in R^+} \frac{k(\alpha) \|\alpha\|^2}{\langle \alpha, x \rangle^2} \left( u_{\sigma, \ell}(x_0, x) - u_{\sigma, \ell}(x_0, \sigma(\alpha)) \right)^2
$$

$$
+ |F(x_0, x)|^2 \left( \sum_{j=0}^{N} |\partial_{x_j} F(x_0, x)|^2 \right).$$
Set
\[ B_\sigma = \begin{bmatrix}
\partial_{e_0} u_{\sigma,0} & \partial_{e_0} u_{\sigma,1} & \cdots & \partial_{e_0} u_{\sigma,N} \\
\partial_{e_1} u_{\sigma,0} & \partial_{e_1} u_{\sigma,1} & \cdots & \partial_{e_1} u_{\sigma,N} \\
\vdots & \vdots & \ddots & \vdots \\
\partial_{e_N} u_{\sigma,0} & \partial_{e_N} u_{\sigma,1} & \cdots & \partial_{e_N} u_{\sigma,N}
\end{bmatrix}. \]

Let \( \mathbf{B} = \{B_\sigma\}_{\sigma \in G} \) be a matrix with \( N + 1 \) rows and \( (N + 1) \cdot |G| \) columns. It represents a linear operator (denoted by \( \mathbf{B} \)) from \( \mathbb{R}^{(N+1) \cdot |G|} \) into \( \mathbb{R}^{1+1} \). Let \( \|\mathbf{B}\| \) be its norm.

Observe that for \( 0 < q < 1 \) we have
\[
(2 - q) \sum_{j=0}^{N} \left( (\partial_{\mathbf{e}_j} F) \cdot F \right)^2 \leq (2 - q) |F|^2 \|\mathbf{B}\|^2.
\]

Clearly,
\[
\|\mathbf{B}\|^2 \leq \sum_{\sigma \in G} \|B_\sigma\|^2, \quad \|\mathbf{B}\|^2_{\text{HS}} = \sum_{\sigma \in G} \|B_\sigma\|^2_{\text{HS}}.
\]

Therefore the inequality (6.15) will be proven if we show that
\[
(2 - q) \sum_{\sigma \in G} \|B_\sigma\|^2 \leq \sum_{\sigma \in G} \|B_\sigma\|^2_{\text{HS}}
\]
(6.16)
\[
+ \frac{1}{2} \sum_{\sigma \in G} \sum_{\ell = 0}^{N} \sum_{\alpha \in R^+} k(\alpha) \|\alpha\|^2 \left( u_{\alpha,\ell}(x_0, x) - u_{\alpha,\ell}(x_0, \sigma_\alpha(x)) \right)^2.
\]

Recall that
\[
\gamma = \sum_{j=1}^{N} \sum_{\alpha \in R^+} \frac{k(\alpha) \langle \alpha, e_j \rangle^2}{\|\alpha\|^2} = \sum_{j=0}^{N} \sum_{\alpha \in R^+} \frac{k(\alpha) \langle \alpha, e_j \rangle^2}{\|\alpha\|^2}
\]
(see (3.1)). By applying first the Cauchy-Riemann equations (2.4) and next the Cauchy-Schwarz inequality, we obtain
\[
(\text{tr} B_\sigma)^2 = \left( -\sum_{j=1}^{N} \sum_{\alpha \in R^+} k(\alpha) \langle \alpha, e_j \rangle \frac{u_{\alpha,j}(x_0, x) - u_{\alpha,j}(x_0, \sigma_\alpha(x))}{\langle \alpha, x \rangle} \right)^2
\]
(6.17)
\[
\leq \left( \sum_{j=1}^{N} \sum_{\alpha \in R^+} \frac{k(\alpha) \langle \alpha, e_j \rangle^2}{\|\alpha\|^2} \right) \left( \sum_{j=1}^{N} \sum_{\alpha \in R^+} \|\alpha\|^2 k(\alpha) \left( u_{\alpha,j}(x_0, x) - u_{\alpha,j}(x_0, \sigma_\alpha(x)) \right)^2 \right)
\]
\[
\leq \gamma \sum_{j=0}^{N} \sum_{\alpha \in R^+} \|\alpha\|^2 k(\alpha) \frac{\left( u_{\alpha,j}(x_0, x) - u_{\alpha,j}(x_0, \sigma_\alpha(x)) \right)^2}{\langle \alpha, x \rangle^2}.
\]
Utilising again the Cauchy-Riemann equations (2.4), we get

\[
\sum_{0 \leq i < j \leq N} \left( \partial_{e_i} u_{\sigma,j}(x_0, x) - \partial_{e_j} u_{\sigma,i}(x_0, x) \right)^2
= \sum_{j=1}^{N} \left( \sum_{\alpha \in \mathbb{R}^+} k(\alpha) \langle \alpha, e_j \rangle \frac{u_{\sigma,0}(x_0, x) - u_{\sigma,0}(x_0, \sigma(x))}{\langle \alpha, x \rangle} \right)^2
\]
\[
+ \sum_{1 \leq i < j \leq N} \left( \sum_{\alpha \in \mathbb{R}^+} -k(\alpha) \langle \alpha, e_i \rangle \frac{u_{\sigma,j}(x_0, x) - u_{\sigma,j}(x_0, \sigma(x))}{\langle \alpha, x \rangle} \right)^2
\]
\[
+ k(\alpha) \langle \alpha, e_j \rangle \frac{u_{\sigma,i}(x_0, x) - u_{\sigma,i}(x_0, \sigma(x))}{\langle \alpha, x \rangle} \right)^2
\]
\[
\leq 2 \left( \sum_{j=0}^{N} \sum_{\alpha \in \mathbb{R}^+} \frac{k(\alpha) \langle \alpha, e_j \rangle^2}{\|\alpha\|^2} \right) \left( \sum_{j=0}^{N} \sum_{\alpha \in \mathbb{R}^+} \|\alpha\|^2 k(\alpha) \frac{u_{\sigma,j}(x_0, x) - u_{\sigma,j}(x_0, \sigma(x))}{\langle \alpha, x \rangle^2} \right)^2.
\]

Using the auxiliary Lemma 6.11 together with (6.17) and (6.18) we have that for every \(\varepsilon > 0\) there is \(0 < \delta < 1\) such that

\[
\sum_{\sigma \in G} \|B_{\sigma}\|^2 \leq (1 - \delta) \sum_{\sigma \in G} \|B_{\sigma}\|^2_{HS}
\]
\[
(6.19)
\]
\[
+ 3\varepsilon \gamma \sum_{\sigma \in G} \sum_{j=0}^{N} \sum_{\alpha \in \mathbb{R}^+} \|\alpha\|^2 k(\alpha) \frac{u_{\sigma,j}(x_0, x) - u_{\sigma,j}(x_0, \sigma(x))}{\langle \alpha, x \rangle^2}.
\]

Taking \(\varepsilon > 0\) such that \(3\varepsilon \gamma \leq \frac{1}{4}\) and utilizing (6.19) we deduce that (6.16) holds for \(q\) such that \((1 - \delta) \leq (2 - q)^{-1}\).

\[\square\]

7. Harmonic functions in the Dunkl setting.

In this section we characterize certain \(\mathcal{L}\)-harmonic functions in the half-space \(\mathbb{R}^{1+N}\) by adapting the classical proofs (see, e.g., [12], [24] and [26]). Let us first construct an auxiliary barrier function.

**Barrier function.** For fixed \(\delta > 0\) let \(v_1, \ldots, v_s \in \mathbb{R}^N\) be a set of vectors of the unit sphere in \(S^{N-1} = \{x \in \mathbb{R}^N : \|x\| = 1\}\) which forms a \(\delta\)-net on \(S^{N-1}\). Let \(M, \varepsilon > 0\). Define

\[
\mathcal{V}_m(x_0, x) = 2M\varepsilon x_0 + \varepsilon E \left( \frac{\varepsilon}{4} x, v_m \right) \cos \left( \frac{\varepsilon}{4} x_0 \right)
\]
\[(7.1)\]

(cf. [24, Chapter VII, Section 1.2] in the classical setting). The function \(\mathcal{V}_m\) is \(\mathcal{L}\)-harmonic and strictly positive on \([0, \varepsilon^{-1}] \times \mathbb{R}^N\). Set

\[
\mathcal{V}(x_0, x) = \sum_{m=1}^{s} \mathcal{V}_m(x_0, x).
\]
By Corollary 4.21,

\begin{equation}
\lim_{|x| \to \infty} \mathcal{V}(x_0, x) = \infty \quad \text{uniformly in } x_0 \in [0, \varepsilon^{-1}].
\end{equation}

**Maximum principle and the mean value property.** As we have already remarked in Section 2, the operator $\mathcal{L}$ is the Dunkl-Laplace operator associated with the root system $R$ as a subset of $\mathbb{R}^{1+N} = \mathbb{R} \times \mathbb{R}^N$. We shall denote the element of $\mathbb{R}^{1+N}$ by $x = (x_0, x)$. The associated measure will be denoted by $w$. Clearly, $dw(x) = w(x) \, dx \, dx_0$. Moreover, $E(x, y) = e^{x_0 y} E(x, y)$. We shall slightly abuse notation and use the same letter $\sigma$ for the action of the group $G$ in $\mathbb{R}^{1+N}$, so $\sigma(x) = (x_0, \sigma(x))$.

The following weak maximum principle for $\mathcal{L}$-subharmonic functions was actually proved in Theorem 4.2 of Rösler [18].

**Theorem 7.3.** Let $\Omega \subset \mathbb{R}^{1+N}$ be open, bounded, and $\Omega \subset (0, \infty) \times \mathbb{R}^N$. Assume that $\Omega$ is $G$-invariant, that is, $(x_0, \sigma(x)) \in \Omega$ for $(x_0, x) \in \Omega$ and all $\sigma \in G$. Let $f \in C^2(\Omega) \cap C(\overline{\Omega})$ be real-valued and $\mathcal{L}$-subharmonic. Then

\[
\max_{\overline{\Omega}} f = \max_{\partial\Omega} f.
\]

Let $f^{(r)}(x) = \chi_{B(0, r)}(x)$ be the characteristic function of the ball in $\mathbb{R}^{1+N}$. Set

\[
f(r, x, y) = \tau_x f^{(r)}(-y).
\]

Clearly, $0 \leq f(r, x, y) \leq 1$. The following mean value theorem was proved in [14, Theorem 3.2].

**Theorem 7.4.** Let $\Omega \subset \mathbb{R}^{1+N}$ be an open and $G$-invariant set and let $u$ be a $C^2$ function in $\Omega$. Then $u$ is $\mathcal{L}$-harmonic if and only if $u$ has the following mean value property: for all $x \in \Omega$ and $\rho > 0$ such that $B(x, \rho) \subset \Omega$ we have

\[
u(x) = \frac{1}{w(B(0, r))} \int_{\Omega} f(r, x, y) u(y) \, dw(y) \quad \text{for } 0 < r < \rho/3.
\]

**Characterizations of $\mathcal{L}$-harmonic functions in the upper half-space.**

**Theorem 7.5.** Suppose that $u$ is a $C^2$ function on $\mathbb{R}^{1+N}_+$. Then $u$ is a Poisson integral of a bounded function on $\mathbb{R}^N$ if and only if $u$ is $\mathcal{L}$-harmonic and bounded.

**Proof.** The proof is identical to that of Stein [24]. Clearly, the Poisson integral of a bounded function is bounded and $\mathcal{L}$-harmonic. To prove the converse assume that $u$ is $\mathcal{L}$-harmonic and bounded, so $|u| \leq M$. Set $f_n(x) = u \left( \frac{1}{n} \cdot x \right)$ and $u_n(x_0, x) = P_{x_0} f_n(x)$. Then $U_n(x_0, x) = u(x_0 + \frac{1}{n}, x) - u_n(x_0, x)$ is $\mathcal{L}$-harmonic, $|U_n| \leq 2M$, continuous on $[0, \infty) \times \mathbb{R}^N$, and $U_n(0, x) = 0$. We shall prove that $U_n \equiv 0$. Fix $(y_0, y) \in \mathbb{R}^{1+N}_+$. Set

\[
U(x_0, x) = U_n(x_0, x) + \mathcal{V}(x_0, x)
\]

and consider the function $U$ on the closure of the set $\Omega = (0, \varepsilon^{-1}) \times B(0, R)$, with $\varepsilon > 0$ small and $R$ large enough. Then $U$ is $\mathcal{L}$-harmonic in $\Omega$, continuous on $\Omega$, and positive.
on the boundary of the $\partial \Omega$. Thus, by the maximum principle, $U$ is positive in $\Omega$, so

$$U_n(y_0,y) > -2M\varepsilon y_0 - \sum_{m=1}^{s} \varepsilon E\left(\frac{\varepsilon \pi}{4} y, v_m\right) \cos \left(\frac{\varepsilon \pi}{4} y_0\right).$$

Letting $\varepsilon \to 0$ we obtain $U_n(y_0,y) \geq 0$. The same argument applied to $-u$ gives $-U_n(y_0,y) \geq 0$, so $U_n \equiv 0$, which can be written as

$$u(x_0 + \frac{1}{n}, x) = P_{x_0}f_n(x) = \int p_{x_0}(x,y)f_n(y) \, dw(y). \tag{7.6}$$

Clearly $|f_n| \leq M$, so by the $\ast$-weak compactness, there is a subsequence $n_j$ and $f \in L^\infty(R^N)$ such that for $\varphi \in L^1(dw)$, we have

$$\lim_{j \to \infty} \int \varphi(y)f_{n_j}(y) \, dw(y) = \int \varphi(y)f(y) \, dw(y).$$

So,

$$u(x_0, x) = \lim_{j \to \infty} u\left(x_0 + \frac{1}{n_j}, x\right) = \lim_{j \to \infty} \int p_{x_0}(x,y)f_{n_j}(y) \, dw(y)$$

$$= \int p_{x_0}(x,y)f(y) \, dw(y).$$

\[\square\]

**Corollary 7.7.** If $u$ is $\mathcal{L}$-harmonic and bounded in $\mathbb{R}^{1+N}_+$ then $u$ has a nontangential limit at almost every point of the boundary.

**Theorem 7.8.** Suppose that $u$ is a $C^2$-function on $\mathbb{R}^{1+N}_+$. If $1 < p < \infty$ then $u$ is a Poisson integral of an $L^p(dw)$ function if and only if $u$ is $\mathcal{L}$-harmonic and

$$\sup_{x_0 > 0} \|u(x_0, \cdot)\|_{L^p(dw)} < \infty. \tag{7.9}$$

If $p = 1$ then $u$ is a Poisson integral of a bounded measure $\omega$ if and only if $u$ is $\mathcal{L}$-harmonic and

$$\sup_{x_0 > 0} \|u(x_0, \cdot)\|_{L^1(dw)} < \infty. \tag{7.10}$$

Moreover, if $u^* \in L^1(dw)$ (see (2.6)), then $d\omega(x) = f(x)dw(x)$, where $f \in L^1(dw)$.

**Proof.** Assume that either (7.9) or (7.10) holds. Then, by Theorem 7.4, for every $\varepsilon > 0$

$$\sup_{x_0 > 0} \sup_{x \in \mathbb{R}^N} |u(x_0 + \varepsilon, x)| \leq C_\varepsilon < \infty. \tag{7.11}$$

Set $f_n(x) = u(\frac{1}{n}, x)$. From Theorem 7.5 we conclude that $u(\frac{1}{n} + x_0, x) = P_{x_0}f_n(x)$. Moreover, there is a subsequence $n_j$ such that $f_{n_j}$ converges weakly-$\ast$ to $f \in L^p(dw)$ (if $1 < p < \infty$) or to a measure $\omega$ (if $p = 1$). In both cases $u$ is the Poisson integral either of $f$ or $\omega$. If additionally $u^* \in L^1(dw)$, then the measure $\omega$ is absolutely continuous with respect to $dw$. \[\square\]
Proof of a part of Theorem 2.5. We are now in a position to prove a part of Theorem 2.5, which is stated in the following proposition. The converse is proven at the very end of Section 11 (see Proposition 11.27).

**Proposition 7.12.** Assume that \( u \in H^1_k \). Then

\[
\|u^*\|_{L^1(dw)} \leq C\|u\|_{H^1_k}.
\]

**Proof.** Fix \( \varepsilon > 0 \). Set \( u_{j,\varepsilon}(x_0, x) = u_j(\varepsilon + x_0, x) \), \( f_{j,\varepsilon}(x) = u_j(\varepsilon, x) \). Then, by Theorem 7.4, the \( L \)-harmonic function \( u_{j,\varepsilon}(x_0, x) \) is bounded and continuous on the closed set \([0, \infty) \times \mathbb{R}^N \). In particular \( f_{j,\varepsilon} \in L^\infty \cap L^1(dw) \cap C^2 \). By Theorem 7.5,

\[
u_{j,\varepsilon}(x_0, x) = P_{x_0}f_{j,\varepsilon}(x).
\]

It is not difficult to conclude using (5.8) (with \( m = 0 \)) that \( \lim_{\|(x_0, x)\| \to \infty} |u_{j,\varepsilon}(x_0, x)| = 0 \). Thus also \( \lim_{\|(x, \varepsilon)\| \to \infty} f_{j,\varepsilon}(x) = 0 \). Set \( u_\varepsilon = (u_{0,\varepsilon}, u_{1,\varepsilon}, \ldots, u_{N,\varepsilon}) \). Clearly, \( u_\varepsilon \in H^1_k \). Let \( F_\varepsilon(x_0, x) = F(\varepsilon + x_0, x) \), where \( F(x_0, x) \) is defined by (6.9). Set \( f_\varepsilon(x) = |F(\varepsilon, x)| \).

Let \( 0 < q < 1 \) be as in Theorem 6.12 and \( p = q^{-1} > 1 \). Observe that the function \( |F_\varepsilon(x_0, x)|^q - P_{x_0}(f_\varepsilon^q)(x) \) vanishes for \( x = 0 \) and

\[
\lim_{\|(x_0, x)\| \to \infty} \left( |F_\varepsilon(x_0, x)|^q - P_{x_0}(f_\varepsilon^q)(x) \right) = 0.
\]

So, by Theorem 6.12 and the maximum principle (see Theorem 7.3),

\[
|u(\varepsilon + x_0, x)|^q \leq |F_\varepsilon(x_0, x)|^q \leq P_{x_0}(f_\varepsilon^q)(x).
\]

Set \( u_\varepsilon^*(x) = \sup_{|x-y| < \varepsilon} |u(\varepsilon + x_0, y)| \). Then, by (7.14) and (10.5),

\[
\|u_\varepsilon^*\|_{L^1(dw)} \leq C_p \|f_\varepsilon^p\|_{L^p(dw)} = C_p \|f_\varepsilon\|_{L^1(dw)} \leq C_p \|u\|_{H^1_k}.
\]

Since \( u_\varepsilon^* \to u^* \) as \( \varepsilon \to 0 \) and the convergence is monotone, we use the Lebesgue monotone convergence theorem and get (7.13).

\[\square\]

From Theorem 7.8 and Proposition 7.12 we obtain the following corollary.

**Corollary 7.15.** If \( u \in H^1_k \), then there are \( f_j \in L^1(dw), j = 0, 1, \ldots, N, \) such that \( |f_j(x)| \leq u^*(x) \) and \( u_j(x_0, x) = P_{x_0}f_j(x) \). Moreover, the limit \( \lim_{x_0 \to 0} u_j(x_0, x) = f_j(x) \) exists in \( L^1(dw) \).

8. **Riesz transform characterization of \( H^1_k \)**

**Riesz transforms.** The Riesz transforms in the Dunkl setting are defined by

\[
\mathcal{F}(R_j f)(\xi) = -i \frac{\xi_j}{\|\xi\|} (\mathcal{F} f)(\xi), \quad j = 1, 2, \ldots, N.
\]

They are bounded operators on \( L^2(dw) \). Clearly,

\[
R_j f = -T_{e_j}(-\Delta)^{-1/2} f = -\lim_{\varepsilon \to 0} \lim_{M \to \infty} c \int_\varepsilon^M T_{e_j} e^{t \Delta} f \frac{dt}{\sqrt{t}},
\]

and the convergence is in \( L^2(dw) \) for \( f \in L^2(dw) \). It follows from [3] that \( R_j \) are bounded operators on \( L^p(dw) \) for \( 1 < p < \infty \).
Our task is to define $R_j f$ for $f \in L^1(dw)$. To this end we set

$$\mathcal{T}_k = \{ \varphi \in L^2(dw): (\mathcal{F}\varphi)(\xi)(1 + \|\xi\|^n) \in L^2(dw), \ n = 0, 1, 2, \ldots \}.$$ 

It is not difficult to check that if $\varphi \in \mathcal{T}_k$, then $\varphi \in C_0(\mathbb{R}^N)$ and $R_j \varphi \in C_0(\mathbb{R}^N) \cap L^2(dw)$. Moreover, for fixed $y \in \mathbb{R}^N$ the function $p_t(x, y)$ belongs to $\mathcal{T}_k$. Now $R_j f$ for $f \in L^1(dw)$ is defined in a weak sense as a functional on $\mathcal{T}_k$, by

$$\langle R_j f, \varphi \rangle = - \int_{\mathbb{R}^N} f(x)R_j \varphi(x) \, dw(x).$$

**Proof of Theorem 2.11.** Assume that $f \in L^1(dw)$ is such that $R_j f$ belong to $L^1(dw)$ for $j = 1, 2, \ldots, N$. Set $f_0(x) = f(x)$, $f_j(x) = R_j f(x)$, $u_0(x, \cdot) = P_{x_0} f(x)$, $u_j(x_0, \cdot) = P_{x_0} f_j(x)$. Then $u = (u_0, u_1, \ldots, u_N)$ satisfies (2.4). Moreover,

$$\sup_{x_0 > 0} \int_{\mathbb{R}^N} |u_j(x_0, x)| \, dw(x) \leq \|f_j\|_{L^1(dw)} \text{ for } j = 0, 1, \ldots, N.$$

Thus $u \in \mathcal{H}_k$ and

$$\|f\|_{H^1_{\Delta}} = \|u\|_{\mathcal{H}_k} \leq \|f\|_{L^1(dw)} + \sum_{j=1}^N \|R_j f\|_{L^1(dw)}.$$

We turn to prove the converse. Assume that $f_0 \in H^1_{\Delta}$. By the definition of $H^1_{\Delta}$ there is a system $u = (u_0, u_1, \ldots, u_N) \in \mathcal{H}_k$ such that $f_0(x) = \lim_{x_0 \to 0} u_0(x_0, x)$ (convergence in $L^1(dw)$). Set $f_j(x) = \lim_{x_0 \to 0} u_j(x_0, x)$, where limits exist in $L^1(dw)$ (see Corollary 7.15). We have $u_j(x_0, \cdot) = P_{x_0} f_j(x)$. It suffices to prove that $R_j f_0 = f_j$. To this end, for $\varepsilon > 0$, let $f_{j, \varepsilon}(x) = u_j(\varepsilon, x)$, $u_{j, \varepsilon}(x_0, x) = u_j(x_0 + \varepsilon, x)$. Then $f_{j, \varepsilon} \in L^1(dw) \cap C_0(\mathbb{R}^N)$. In particular $f_{j, \varepsilon} \in L^2(dw)$. Set $g_j = R_j f_{0, \varepsilon}$, $v_j(x_0, x) = P_{x_0} g_j(x)$. Then $v = (u_{0, \varepsilon}, v_1, \ldots, v_N)$ satisfies the Cauchy-Riemann equations (2.4). Therefore, $T_j u_{0, \varepsilon}(x_0, x) = T_0 u_{j, \varepsilon}(x_0, x) = T_0 v_j(x_0, x)$. Hence, $u_{j, \varepsilon}(x_0, \cdot) - v_{j, \varepsilon}(x_0, \cdot) = c_j(x)$. But $\lim_{x_0 \to 0} u_{j, \varepsilon}(x_0, x) = 0 = \lim_{x_0 \to 0} v_j(x_0, \cdot)$ for every $x \in \mathbb{R}^N$. Consequently, $u_{j, \varepsilon}(x_0, \cdot) = v_{j, \varepsilon}(x_0, \cdot)$. Thus, $f_{j, \varepsilon} = R_j f_{0, \varepsilon}$. Since $\lim_{\varepsilon \to 0} f_{j, \varepsilon} = f_j$ in $L^1(dw)$ and $R_j f_{0, \varepsilon} \to R f_0$ in the sense of distributions, we have $f_j = R_j f_0$.

9. **Inclusion $H^1_{(1,q,M)} \subset H^1_{\Delta}$**

In this section we show that the atomic space $H^1_{(1,q,M)}$ with $M > N$ is contained in the Hardy space $H^1_{\Delta}$ and there exists $C = C_{k,q,M}$ such that

$$\|f\|_{H^1_{\Delta}} \leq C \|f\|_{H^1_{(1,q,M)}}. \tag{9.1}$$

Let $f \in H^1_{(1,q,M)}$. According to Theorem 2.11, it is enough to show that $R_j f \in L^1(dw)$ and $\|R_j f\|_{L^1(dw)} \leq C \|f\|_{H^1_{(1,q,M)}}$. By the definition of the atomic space there is a sequence $a_j$ of $(1, q, M)$ atoms and $\lambda_i \in \mathbb{C}$ such that $f = \sum_i \lambda_i a_i$ and $\sum_i |\lambda_i| \leq 2 \|f\|_{H^1_{(1,q,M)}}$. Observe that the series converges in $L^1(dw)$, hence $R_j f = \sum_i \lambda_i R_j a_j$ in the sense of distributions. Therefore it suffices to prove that there is a constant $C > 0$ such $\|R_j a\|_{L^1(dw)} \leq C$ for every $a$ being a $(1, q, M)$-atom. Our proof follows ideas of [15].
b \in \mathcal{D}(\Delta^M) and B(y_0, r) be as in the definition of (1, q, M) atom. Since \( R_j \) is bounded on \( L^q(dw) \), by the Hölder inequality, we have
\[
\|R_j a\|_{L^1(\mathcal{O}(B(y_0, 4r)))} \leq C.
\]
In order to estimate \( R_j a \) on the set \( \mathcal{O}(B(y_0, 4r))^c \) we write
\[
R_j a = c''_k \int_0^\infty T_{j,x} e^{t\Delta} a \frac{dt}{\sqrt{t}}
\]
\[
= c''_k \int_0^r T_{j,x} e^{t\Delta} a \frac{dt}{\sqrt{t}} + c''_k \int_r^\infty T_{j,x} e^{t\Delta} (\Delta)^M b \frac{dt}{\sqrt{t}}
\]
\[
= c''_k \int_0^r T_{j,x} e^{t\Delta} a \frac{dt}{\sqrt{t}} + c''_k \int_r^\infty T_{j,x} e^{t\Delta} M b \frac{dt}{\sqrt{t}}
\]
\[
= R_{j,0} a + R_{j,\infty} a.
\]
Further, using (4.6) with \( m = 0 \) together with (3.2), we get
\[
|R_{j,0} a(x)| \leq C \int_0^r \int_{R^N} t^{-1} w(B(y, \sqrt{t}))^{-1} e^{-cd(x,y)^2/t} |a(y)| \, dw(y) \, dt
\]
(9.2)
\[
\leq C \frac{d(x,y)^{N+1} w(B(y_0, r))}{r^{N+1}}.
\]
To estimate \( R_{j,\infty} a \) we recall that \( \|b\|_{L^1(dw)} \leq r^{2M} \). Using (4.6) with \( m = M \), we obtain
\[
|R_{j,\infty} a(x)| \leq C \int_r^\infty \int_{R^N} t^{-M} w(B(y, \sqrt{t}))^{-1} e^{-cd(x,y)^2/t} |b(y)| \, dw(y) \, dt
\]
(9.3)
\[
\leq C \frac{r^{2M} w(B(y_0, r))}{d(x,y)^{2M}}.
\]
Obviously, (9.2) and (9.3) combined with (3.2) imply \( \|R_j a\|_{L^1(\mathcal{O}(B(y_0, 4r))^c)} \leq C \).

10. Maximal functions

Let \( \Phi(x) \) be a radial continuous function such that \( |\Phi(x)| \leq C(1 + |x|)^{-\kappa - \beta} \) with \( \kappa > N \). Let \( \Phi_t(x) = t^{-N} \Phi(t^{-1} x) \) and \( \Phi_t(x, y) = \tau_x \Phi_t(-y) \). Then, by Corollary 3.10,
\[
|\Phi_t(x, y)| \leq C V(x, y, t)^{-1} \left(1 + \frac{d(x,y)}{t}\right)^{-\beta}.
\]
Set \( M_{\Phi,\alpha} f(x) = \sup_{\|x-y\| < \alpha} |\Phi_t f(y)| \), where
\[
\Phi_t f(x) = \Phi_t \ast f(x) = \int_{R^N} \Phi_t(x, y) f(y) \, dw(y).
\]
If \( a = 1 \), then we simply write \( M_{\Phi} \). We say that \( f \in H^1_{\max, \Phi} \) if \( M_{\Phi} f \in L^1(dw) \). Then we set \( \|f\|_{H^1_{\max, \Phi}} = \|M_{\Phi} f\|_{L^1(dw)} \).

The space \( N \). The space \( H^1_{\max, \Phi} \) is related with the tent space \( N \).
**Definition 10.1.** For $a > 0$, $\lambda > N$, and a function $u(t, x)$ denote
\[
u^*_a(x) = \sup_{|x-y|<at} |u(t, y)|, \quad \nu^*_\lambda(x) = \sup_{y \in \mathbb{R}^N, t>0} |u(t, y)| \left(\frac{t}{\|y-x\|+t}\right)^\lambda.
\]
The tent space $\mathcal{N}$ is defined by
\[
\mathcal{N}_a = \{u(t, x) : \|u\|_{\mathcal{N}_a} = \|\nu^*_a\|_{L^1(dw)} < \infty\}.
\]
If $a = 1$, then we write $\mathcal{N}$, $\|u\|_{\mathcal{N}}$, and $u^*$ (cf. (2.6)).

**Lemma 10.2.** There are constants $C, C_\lambda, c_\lambda > 0$ such that
\[
\|u\|_{\mathcal{N}_\lambda} \leq C \left(\frac{a+b}{b}\right)^N \|u\|_{\mathcal{N}_\lambda},
\]
\[
c_\lambda\|u\|_{\mathcal{N}} \leq \|\nu^*_\lambda\|_{L^1(dw)} \leq C_\lambda\|u\|_{\mathcal{N}}.
\]

**Proof.** The proofs are the same as those in [25, Chapter II] and [13, page 114]. \hfill $\square$

If $\Omega \subset \mathbb{R}^N$ is an open set, then the tent over $\Omega$ is given by
\[
\tilde{\Omega} = \left((0, \infty) \times \mathbb{R}^N\right) \setminus \bigcup_{x \in \Omega^c} \Gamma(x), \quad \text{where} \quad \Gamma(x) = \{(t, y) : \|x-y\| < 4t\}.
\]

The space $\mathcal{N}$ admits the following atomic decomposition (see [25]).

**Definition 10.5.** A function $A(t, x)$ is an atom for $\mathcal{N}$ if there is a ball $B$ such that
- $\text{supp } A \subset \hat{B}$,
- $\|A\|_{L^\infty} \leq w(B)^{-1}$.

Clearly, $\|A\|_{\mathcal{N}} \leq 1$ for every atom $A$ for $\mathcal{N}$. Moreover, every $u \in \mathcal{N}$ can be written as $u = \sum_j \lambda_j A_j$, where $A_j$ are atoms for $\mathcal{N}$, $\lambda_j \in \mathbb{C}$, and $\sum_j |\lambda_j| \leq C\|u\|_{\mathcal{N}}$.

**Proposition 10.6.** Let $u(t, x) = P_t f(x)$, $v(t, x) = t^n \frac{d^n}{dt^n} P_t f(x)$. Then for $f \in L^1(dw)$ we have
\[
\|v\|_{\mathcal{N}} \leq C_n\|u\|_{\mathcal{N}},
\]
where $P_t = e^{-t\sqrt{-\Delta}}$ is the Poisson semigroup.

**Proof.** Assume that $\|u\|_{\mathcal{N}} < \infty$. Clearly, $v(t, x) = 2^n Q_{t/2} P_{t/2} f(x)$, where $Q_t = t^n \frac{d^n}{dt^n} P_t$. Set $u^{(1)}(t, x) = u(\frac{t}{2}, x)$. Then
\[
\|u^{(1)}\|_{\mathcal{N}} \leq C\|u\|_{\mathcal{N}}.
\]
By the atomic decomposition we write $u^{(1)} = \sum_j c_j A_j$, where $A_j$ are atoms for $\mathcal{N}$, $c_j \in \mathbb{C}$, and $\sum |c_j| \lesssim \|u\|_{\mathcal{N}}$, (see Definition 10.5). Thus, by Lemma 10.2, we have
\[
v(t, x) = 2^n \sum_j c_j Q_{t/2} A_j(t, x),
\]
\[
Q_{t/2} A_j(t, x) = \int Q_{t/2}(x, y) A_j(t, y) dw(y).
\]
From Proposition 5.4 and the definition of $\mathcal{N}$ atoms we conclude that $\|Q_{t/2} A_j(t, x)\|_{\mathcal{N}} \leq C$. \hfill $\square$
Calderón reproducing formula. Fix a positive integer $m$ sufficiently large. Let $	ilde{\Theta} \in C^m(\mathbb{R})$ be an even function such that $\|\tilde{\Theta}\|_{S^m} < \infty$ (see (3.11)). Set $\Theta(x) = \tilde{\Theta}(\|x\|)$. Assume that $\int_{\mathbb{R}^N} \Theta(x) \, dw(x) = 0$. The Plancherel theorem for the Dunkl transform implies
\[
\|\Theta_t * f(x)\|_{L^2(\mathbb{R}^1_+, dw(x)\, \|x\|)} \leq C\|f\|_{L^2(dw)}.
\]
By duality,
\[
\|\pi_{\Theta} F(x)\|_{L^2(dw(x))} \leq C\|F(t, x)\|_{L^2(\mathbb{R}^1_+, dw(x)\, \|x\|)},
\]
where
\[
\pi_{\Theta} F(x) = \int_0^{\infty} (\Theta_t * F(t, \cdot))(x) \frac{dt}{t} = \int_0^{\infty} \int_{\mathbb{R}^N} \Theta_t(x, y) F(t, y) \, dw(y) \frac{dt}{t}.
\]

Let $\Phi(x) \geq 0$ be a radial $C^\infty$ real-valued function on $\mathbb{R}^N$ supported by $B(0, 1/4)$, $\Phi(x) \equiv 1$ on $B(0, 1/8)$. Let $\kappa$ be a positive integer, $\kappa > N/2$. Set
\[
\Psi(x) = \Delta^{2\kappa}(\Phi * \Phi)(x) = (\Delta^\kappa \Phi)(x).
\]
Then $\Psi$ is radial and real-valued,
\[
\text{supp} \, \Psi \subset B(0, 1/2),
\]
\[
\int \Psi(x) \, dw(x) = 0,
\]
\[
\mathcal{F} \Psi(\xi) = c_k \|\xi\|^{4\kappa} \mathcal{F} \Phi(\xi)^2 = c_k \|\xi\|^{4\kappa} \mathcal{F}^2 \Phi(\xi)^2.
\]
Clearly,
\[
\Phi_t(x, y) = \Psi_t(x, y) = 0 \quad \text{if} \quad d(x, y) > t/2
\]
and
\[
\int \Psi_t(x, y) \, dw(y) = \int \Psi_t(x, y) \, dw(x) = 0.
\]
Moreover, for $n = 0, 1, 2, \ldots$, and $f \in L^2(dw)$ we have the Calderón reproducing formulae:
\[
f = c'_n \int_0^\infty \Psi_t n^\kappa \Phi_t n (\sqrt{\Delta})^n e^{-t\sqrt{\Delta}} f \frac{dt}{t} = c' \int_0^\infty t^2 \Psi_t e^{t^2} \Delta \Phi \frac{dt}{t}
\]
and the integrals converge in the $L^2(dw)$-norm.

Fix a positive integer $m$ (large enough). Let $\Phi^{(j)}(x) = \tilde{\Phi}^{(j)}(\|x\|), j = 1, 2$, where $\tilde{\Phi}^{(j)}$ are even $C^m$-functions such that $\|\tilde{\Phi}^{(j)}\|_{S^m} < \infty$ and
\[
\int_{\mathbb{R}^N} \Phi^{(j)}(x) \, dw(x) = 1, \quad j = 1, 2.
\]
Taking instead of $\Phi^{(j)}$ their dilations $\Phi^{(j)}_s(x) = s^{-N} \Phi^{(j)}(x/s)$ if necessary, we may assume that
\[
f = c''_j \int_0^\infty \Psi_t \Phi^{(j)}_t f \frac{dt}{t}, \quad f \in L^2(dw), \quad j = 1, 2,
\]
where the integrals converge in the $L^2$-norm. Moreover, by Lemma 10.2, there is a constant $C_s > 0$ such that if $u^{(j)}(t, x) = \Phi^{(j)}_t f(x)$ and $v^{(j)}(t, x) = \Phi^{(j)}_{ts} f(x) = u(st, x)$, then

$$C_s^{-1} \|v^{(j)}\|_N \leq \|u^{(j)}\|_N \leq C_s \|v^{(j)}\|_N.$$  

We are in a position to state the main results of this section.

**Proposition 10.12.** For $\Phi^{(1)}$ and $\Phi^{(2)}$ as above and every $f \in L^2(dw)$ we have

$$\|\Phi^{(1)}_t f\|_{\mathcal{N}_a} = \|M_{\Phi^{(1)}, \alpha} f\|_{L^1(dw)} \leq C_{\Phi^{(1)}, \Phi^{(2)}, \alpha, \alpha'} \|M_{\Phi^{(2)}, \alpha'} f\|_{L^1(dw)}$$

$$= C_{\Phi^{(1)}, \Phi^{(2)}, \alpha, \alpha'} \|\Phi^{(2)}_t f\|_{\mathcal{N}_{a'}}.$$  

**Proof.** Let $\Psi^{(1)} = \Phi^{(1)} - \Phi^{(2)}$. Then $\Psi^{(1)}$ is radial and thanks to (10.10), we have $\mathcal{F}\Psi^{(1)}(\xi) = O(\|\xi\|^2)$ for $\|\xi\| < 1$. It suffices to prove that

$$\|\Psi^{(1)}_t f\|_{\mathcal{N}} \leq C \|\Phi^{(2)}_t f\|_{\mathcal{N}}.$$  

Using the Calderón reproducing formula (10.11), we obtain

$$\Psi^{(1)}_t f = c'_2 \int_0^\infty \Psi^{(1)}_t \Psi_s \Phi^{(2)}_s f \frac{ds}{s}.$$  

According to Proposition 3.12, for any $\eta, \ell > 0$ the integral kernel $K_{t,s}(y, z)$ of the operator $\Psi^{(1)}_t \Psi_s$ satisfies

$$|K_{t,s}(y, z)| \leq C_{\eta, \ell} \min \left( \frac{t}{s}, \frac{s}{t} \right)^\ell \frac{1}{V(y, z, s + t)} \left(1 + \frac{d(y, z)}{s + t}\right)^{-N-\eta}.$$  

We take $N < \lambda < \eta < \ell$. Then for $\|x - y\| < t$ we have

$$\int |K_{t,s}(y, z)| \left(1 + \frac{d(x, z)}{s}\right)^\lambda dw(z) \leq C' \min \left( \frac{t}{s}, \frac{s}{t} \right)^{\ell - \lambda}.$$  

(10.13)  

Therefore, using (10.13) we obtain,

$$\sup_{\|x - y\| < t} |\Psi^{(1)}_t f(y)| = c'_2 \sup_{\|x - y\| < t} \left| \int_0^\infty \int K_{t,s}(y, z) \Phi^{(2)}_s f(z) dw(z) \frac{ds}{s} \right|$$

$$\leq c'_2 \sup_{z, s} |\Phi^{(2)}_s f(z)| \left(1 + \frac{d(x, z)}{s}\right)^{-\lambda}$$

$$\times \sup_{\|x - y\| < t} \int_0^\infty \int |K_{t,s}(y, z)| \left(1 + \frac{d(x, z)}{s}\right)^\lambda dw(z) \frac{ds}{s}$$

$$\leq C \sup_{z, s} |\Phi^{(2)}_s f(z)| \left(1 + \frac{d(x, z)}{s}\right)^{-\lambda}.$$  

(10.14)  

The proof is complete, by applying (10.4). \qed

**Remark 10.15.** It follows from the proof of Proposition 10.12 that if $\Theta \in \mathcal{S}(\mathbb{R}^N)$ is radial and $\int_{\mathbb{R}^N} \Theta(x) \, dw(x) = 0$, and $\Phi^{(2)}$ is as above, then for $f \in L^2(dw)$ we have

$$\|\Theta_t f\|_{\mathcal{N}} \leq C \|\Phi^{(2)}_t f\|_{\mathcal{N}}.$$
Proposition 10.16. For a function $\Phi^{(1)}$ as described above and $\alpha, \alpha' > 0$ there is a constant $C_{\Phi^{(1)}, \alpha, \alpha'} > 0$ such that

$$\|M_{\Phi^{(1)}, \alpha} f\|_{L^1(dw)} \leq C_{\Phi^{(1)}, \alpha, \alpha'} \|M_{P, \alpha'} f\|_{L^1(dw)}, \text{ for } f \in L^1(dw) \cap L^2(dw),$$

where $P_t = e^{-t \Delta}$ is the Poisson semigroup.

Proof. For a positive integer $n$ (large) set $\phi(\xi) = e^{-\|\xi\|} \left( \sum_{j=0}^{n+1} \frac{\|\xi\|^j}{j!} \right)$. Then

$$\phi(\xi) - 1 = O(\|\xi\|^{n+1}) \text{ for } \|\xi\| < 1.$$ 

So $\phi$ is a $C^n(\mathbb{R}^N)$ function such that $|\partial^\alpha \phi(\xi)| \leq C_{\alpha} \exp(-\|\xi\|/2)$, $|\alpha| \leq n$. Put $\Phi^{(2)} = c_k^{-1} F^{-1} \phi$. Applying Proposition 10.12, we have

$$\|\Phi^{(1)}_t f\|_N \lesssim \|\Phi^{(2)}_t f\|_N.$$ 

Notice that $\frac{dt}{ds} P_t f(x) = F^{-1}(\{\|\xi\|^2 e^{-t\|\xi\|^2} F f(\xi)(x)\}$. Hence, from Proposition 10.6 we conclude,

$$\|\Phi^{(2)}_t f\|_N \leq C \sum_{j=0}^{n+1} \left| \frac{d^j}{ds^j} P_t f \right|_N \leq C' \|P_t f\|_N.$$ 

□

11. Atomic decompositions; Inclusions $H^1_{\max, P} \subset H^1_{(1, \infty, M)}$ and $H^1_{\max, H} \subset H^1_{(1, \infty, M)}$

Note that Proposition 10.16 implies that $H^1_{\max, P} \cap L^2(dw) \subset H^1_{\max, H}$ and

$$\|\mathcal{M}_{H} f\|_{L^1(dw)} \leq C \|\mathcal{M}_{P} f\|_{L^1(dw)} \text{ for } f \in L^2(dw).$$

Lemma 11.2. $H^1_{\max, H} \subset H^1_{\max, P}$ and there is a constant $C > 0$ such that

$$\|\mathcal{M}_{P} f\|_{L^1(dw)} \leq C \|\mathcal{M}_{H} f\|_{L^1(dw)} \text{ for } f \in L^1(dw).$$

Proof. The proof is standard. Let $f \in L^1(dw)$. Set $u(t, x) = e^{t^2 \Delta} f(x)$. By the subordination formula (2.2) for fixed $t > 0$ we have

$$\sup_{\|x'-x\| < t} |P_t f(x')| \leq \frac{1}{2\sqrt{\pi}} \int_0^\infty \sup_{\|x'-x\| < t} |u(ts, x')| e^{-\frac{1}{2t^2} ds} s^2 \leq \frac{1}{2\sqrt{\pi}} \int_0^\infty u^{**}(s) \left( \frac{1 + s \lambda}{s} \right) e^{-\frac{1}{4s^2} ds} \leq C u^{**}(x).$$

Now the lemma follows from (10.4). □
Let us note that (11.1) and (11.3) imply that $H_{\text{max},H}^1 \cap L^2(dw) = H_{\text{max},P}^1 \cap L^2(dw)$ and

$$\|M_P f\|_{L^1(dw)} \sim \|M_H f\|_{L^1(dw)} \quad \text{for } f \in L^2(dw).$$

In the next theorem we show that all elements in $H_{\text{max},H}^1 \cap L^2(dw) = H_{\text{max},P}^1 \cap L^2(dw)$ admit atomic decompositions into $(1, \infty, M)$-atoms. The $L^2(dw)$ condition is removed afterwards in Theorem 11.25.

**Theorem 11.4.** For every positive integer $M$ there is a constant $C_M > 0$ such that every element $f \in H_{\text{max},H}^1 \cap L^2(dw) = H_{\text{max},P}^1 \cap L^2(dw)$ can be written as

$$f = \sum \lambda_j a_j$$

where $a_j$ are $(1, \infty, M)$-atoms, $\sum |\lambda_j| \leq C_M \|M_P f\|_{L^1(dw)}$. Moreover, the convergence is in $L^2(dw)$.

**Proof.** The proof is a straightforward adaptation of [27] with the difference that tents are now constructed with respect to the orbit distance $d(x, y)$. We include details for the convenience of readers unfamiliar with [27]. More experienced readers may skip the proof and jump to Lemma 11.21. Without loss of generality, we may assume that $M$ is an even integer $> 2N$.

**Step 1. Reproducing formulae.** Let $\Phi$, $\Psi$ be as in the Calderón reproducing formula with $\kappa = M/2$ (see Section 10). Denote

$$\varphi(\xi) = F(\Phi)(\xi) = \tilde{\varphi}(||\xi||),$$

$$\psi(\xi) = F(\Psi)(\xi) = c_k ||\xi||^{2M} |\varphi(\xi)|^2 = \tilde{\psi}(||\xi||) = c_k ||\xi||^{2M} |\tilde{\varphi}(||\xi||)|^2.$$  

Then there is a constant $c$ such that

$$f = \lim_{\varepsilon \to 0} c \int_{\varepsilon}^{\varepsilon^{-1}} \Psi \int_2^t e^{t^2 - t^2} f \frac{dt}{t}$$

with convergence in $L^2(dw)$. We have

$$F f(\xi) = \lim_{\varepsilon \to 0} c k \int_{\varepsilon}^{\varepsilon^{-1}} t^2 ||\xi||^{2} \tilde{\psi}(t||\xi||) e^{-t^2 ||\xi||^2} F f(\xi) \frac{dt}{t},$$

For $\xi \neq 0$ set

$$\eta(\xi) = c_k \int_{1}^{\infty} t^2 ||\xi||^{2} \tilde{\psi}(t||\xi||) e^{-t^2 ||\xi||^2} \frac{dt}{t} = c_k \int_{||\xi||}^{\infty} t^2 \tilde{\psi}(t) e^{-t^2} \frac{dt}{t}.$$  

Put $\eta(0) = 1$. Then $\eta$ is a Schwartz class radial real-valued function. Set $\Xi(x) = c_k^{-1} F^{-1} \eta(x)$. Then $\Xi \in S(\mathbb{R}^N)$, $\int \Xi(x) dw(x) = 1$, and

$$c \int_{a}^{b} \Psi \int_2^t e^{t^2 - t^2} f \frac{dt}{t} = \Xi_a f - \Xi_b f.$$

**Step 2. Space of orbits.** Let $X = \mathbb{R}^N/G$ be the space of orbits equipped with the metric $d(O(x), O(y)) = d(x, y)$ and the measure $m(A) = w \left( \bigcup_{O(x) \in A} O(x) \right)$. So $(X, d, m)$ is the space of homogeneous type in the sense of Coifman–Weiss. The space
X can be identified with a positive Weyl chamber. Any open set in X of finite measure admits the following easily proved Whitney type covering lemma.

**Lemma 11.6.** Suppose that $\Omega \subset X$ is an open set with finite measure. Then there is a sequence of balls $B_X(\mathcal{O}(x_{(n)}), r_{(n)})$ such that $r_{(n)} = d(\mathcal{O}(x_{(n)}), \Omega^c)$,

$$
\bigcup_{n \in \mathbb{N}} B_X(\mathcal{O}(x_{(n)}), r_{(n)}/2) = \Omega,
$$

the balls $B_X(\mathcal{O}(x_{(n)}), r_{(n)}/10)$ are disjoint.

**Step 3. Decomposition of $\mathbb{R}^{N+1}_+$**. Assume that $f \in H^1_{\text{max},H} \cap L^2(dw)$. Let

$$
F(t, x) = \left( |t^2 \Delta e^{t^2} f(x)| + |\Xi_t f(x)| \right),
$$

$$
\mathcal{M}f(x) = \sup_{d(x,y)<5t} F(t, y) = \sup_{|x-y|<5t} F(t, y).
$$

Then, by Proposition 10.12 and Remark 10.15, we have $\|\mathcal{M}f\|_{L^1(dw)} \leq C\|f\|_{H^1_{\text{max},H}}$.

Observe that $\mathcal{M}f(\sigma(x)) = \mathcal{M}f(x)$. Therefore $\mathcal{M}f(x)$ can be identified with the function $\mathcal{M}f(\mathcal{O}(x))$ on $X$, moreover $\|\mathcal{M}f(x)\|_{L^1(dw)} = \|\mathcal{M}f(\mathcal{O}(x))\|_{L^1(m)}$. For an open set $\Omega \subset X$ let

$$
\hat{\Omega} = \{(t, \mathcal{O}(x)) : B_X(\mathcal{O}(x), 4t) \subset \Omega \}
$$

be the tent over $\Omega$. For $j \in \mathbb{Z}$ define

$$
\Omega_j = \{ \mathcal{O}(x) \in X : \mathcal{M}f(\mathcal{O}(x)) > 2^j \}, \quad \Omega_j = \{ x \in \mathbb{R}^N : \mathcal{M}f(x) > 2^j \}.
$$

Then $\Omega_j$ is open in $X$, $\Omega_j = \bigcup_{\mathcal{O}(x) \in \Omega_j} \mathcal{O}(x)$, $m(\Omega_j) = w(\Omega_j)$,

$$
\sum_j 2^j w(\Omega_j) \sim \|\mathcal{M}f\|_{L^1(dw)} \sim \|f\|_{H^1_{\text{max},H}}.
$$

Clearly, $\hat{\Omega}_j = \{(t, x) \in \mathbb{R}^{N+1}_+ : (t, \mathcal{O}(x)) \in \hat{\Omega}_j \}$. Set $T_j = \hat{\Omega}_j \setminus \hat{\Omega}_{j+1}$. Then,

$$
\text{supp} F(t, x) \subset \bigcup_{j \in \mathbb{Z}} \hat{\Omega}_j = \bigcup_{j \in \mathbb{Z}} (\hat{\Omega}_j \setminus \hat{\Omega}_{j+1}) = \bigcup_{j \in \mathbb{Z}} T_j
$$

Let $B_X(\mathcal{O}(x_{(n,j)}), r_{(n,j)}/2)$, $x_{(n,j)} \in \mathbb{R}^N$, $n = 1, 2, \ldots$, be a Whitney covering of $\Omega_j$. Set

$$
Q_{(n,j)} = \{ x \in \mathbb{R}^N : \mathcal{O}(x) \in B_X(\mathcal{O}(x_{(n,j)}), r_{(n,j)}/2) \} = \mathcal{O}(B(x_{(n,j)}, r_{(n,j)}/2)).
$$

Obviously, $w(B(x_{(n,j)}, r_{(n,j)}/2)) \leq w(Q_{(n,j)}) \leq |G| w(B(x_{(n,j)}, r_{(n,j)}/2))$. We define a cone over a $G$-invariant set $E$ as

$$
\mathcal{R}(E) = \{(t, y) : d(y, E) < 2t \}.
$$

For $n = 1, 2, \ldots$, let

$$
T_{(n,j)} = T_j \cap \left( \mathcal{R}(Q_{(n,j)}) \setminus \bigcup_{i=0}^{n-1} \mathcal{R}(Q_{(i,j)}) \right), \quad \mathcal{R}(Q_{(0,j)}) = \emptyset.
$$
Clearly, \( \hat{\Omega}_j \subset \bigcup_{n \in \mathbb{N}} \mathcal{R}(Q_{\{n,j\}}) \), \( T_{\{n,j\}} \cap T_{\{n',j'\}} = \emptyset \) if \( (j,n) \neq (j',n') \). Thus we have
\begin{equation}
\text{supp } F(t, x) \subset \bigcup_{j \in \mathbb{Z}, n \in \mathbb{N}} T_{\{n,j\}}.
\end{equation}

**Step 4. Decomposition of \( f \) and \( L^2(dw) \)-convergence.** Write
\begin{equation}
f = \sum_{j \in \mathbb{Z}, n \in \mathbb{N}} c \int_0^\infty \Psi_t \left( \chi_{T_{\{n,j\}}} t^2 e^{t^2} f \right) \frac{dt}{t} = \sum_{j \in \mathbb{Z}, n \in \mathbb{N}} \lambda_{\{n,j\}} a_{\{n,j\}},
\end{equation}
where \( \lambda_{\{n,j\}} = 2^j w(Q_{\{n,j\}}) \),
\begin{align*}
a_{\{n,j\}} &= (\lambda_{\{n,j\}})^{-1} c \int_0^\infty \Psi_t \left( \chi_{T_{\{n,j\}}} t^2 (-\Delta) e^{t^2} f \right) \frac{dt}{t} \\
&= (\lambda_{\{n,j\}})^{-1} c \int_0^\infty t^{2M} (-\Delta)^M \Phi_t \Phi_t \left( \chi_{T_{\{n,j\}}} t^2 (-\Delta) e^{t^2} f \right) \frac{dt}{t}.
\end{align*}
and, thanks to (10.8), the convergence is in \( L^2(dw) \), because \( T_{\{n,j\}} \) are pairwise disjoint.

**Step 5. What remains to prove.** Our task is to prove that the functions \( a_{\{n,j\}} \) are proportional to \( (1, \infty, M) \)-atoms. If this is done then
\[
\sum_{j \in \mathbb{Z}, n \in \mathbb{N}} |\lambda_{\{n,j\}}| = \sum_{j \in \mathbb{Z}, n \in \mathbb{N}} 2^j w(Q_{\{n,j\}}) \lesssim \sum_{j \in \mathbb{Z}} 2^j w(\Omega_j) \sim \|f\|_{H^{1}_{\text{max}, H}},
\]
which proves the atomic decomposition.

**Step 6. Functions \( b_{\{n,j\}} \). Support of \( \Delta^m b_{\{n,j\}} \) for \( m = 0, 1, \ldots, M \).** Observe that
\begin{equation}
a_{\{n,j\}} = (\lambda_{\{n,j\}})^{-1} c \int_0^{r_{\{n,j\}}} \Psi_t \left( \chi_{T_{\{n,j\}}} t^2 (-\Delta) e^{t^2} f \right) \frac{dt}{t} \\
= (\lambda_{\{n,j\}})^{-1} c \int_0^{r_{\{n,j\}}} t^{2M} (-\Delta)^M \Phi_t \Phi_t \left( \chi_{T_{\{n,j\}}} t^2 (-\Delta) e^{t^2} f \right) \frac{dt}{t}.
\end{equation}
Indeed, if \( t > r_{\{n,j\}} \) and \( (t, y) \in \mathcal{R}(Q_{\{n,j\}}) \) then
\begin{equation}
d(y, (\Omega_j)^c) \leq d(y, Q_{\{n,j\}}) + \frac{1}{2} r_{\{n,j\}} + d(x_{\{n,j\}}, (\Omega_j)^c) \leq 2t + \frac{1}{2} t + t = \frac{7}{2} t.
\end{equation}
Hence \( (t, y) \notin T_{\{n,j\}} \).

As a consequence of (10.9), (11.10), and (11.11), we have
\begin{equation}
\text{supp } a_{\{n,j\}} \subset \left\{ x \in \mathbb{R}^N : d(x, x_{\{n,j\}}) \leq \frac{7}{2} r_{\{n,j\}} \right\} = \mathcal{O} \left( B \left( x_{\{n,j\}}, \frac{7}{2} r_{\{n,j\}} \right) \right).
\end{equation}
Let
\[
b_{\{n,j\}} = (\lambda_{\{n,j\}})^{-1} c \int_0^{r_{\{n,j\}}} t^{2M} \Phi_t \Phi_t \left( \chi_{T_{\{n,j\}}} t^2 (-\Delta) e^{t^2} f \right) \frac{dt}{t}.
\]
Then \( b_{\{n,j\}} \in \mathcal{D}(\Delta^M) \),
\[
(-\Delta)^m b_{\{n,j\}} = (\lambda_{\{n,j\}})^{-1} c \int_0^{r_{\{n,j\}}} t^{2M} (-\Delta)^m \Phi_t \Phi_t \left( \chi_{T_{\{n,j\}}} t^2 (-\Delta) e^{t^2} f \right) \frac{dt}{t}.
\]
for $m = 1, 2, \ldots M$, and, by the same arguments,

$$\text{supp } \Delta^m b_{[n,j]} \subset \mathcal{O}\left( B\left( x_{[n,j]}, \frac{7}{2} r_{[n,j]} \right) \right).$$

(11.13)

Note also that $\Delta^m b_{[n,j]}(x) \neq 0$ implies that there is $(t, y) \in \hat{\Omega}_j$ such that $d(x, y) \leq t$. Then $\mathcal{O}(x) \in B_X(\mathcal{O}(y), t) \subset B_X(\mathcal{O}(y), 4t) \subset \Omega_j$. Hence,

$$\text{supp } \Delta^m b_{[n,j]} \subset \Omega_j.$$  

(11.14)

**Step 7. Size of $\Delta^m b_{[n,j]}$ for $m = 0, 1, \ldots, M - 1$.** Suppose that $(t, y)$ is such that $\chi_{t, y} = 1$. Then $(t, y) \in (\hat{\Omega}_{j+1})^c$, so $|t^2 \Delta e^{t^2 \Delta} f(y)| \leq 2^{j+1}$. Consequently,

$$|\Delta^m b_{[n,j]}(x)| = \frac{c}{\lambda_{[n,j]}} \left| \int_0^{r_{[n,j]}} t^{2M-2m} \left( t^2 (-\Delta) \right)^m \Phi_t \Phi_t \chi_{t, y} \left( t, y \right) t^2 (-\Delta) e^{t^2 \Delta} f(y) dx \right| dt \ dt$$

$$= (\lambda_{[n,j]})^{-1} c \left| \int_0^{r_{[n,j]}} t^{2M-2m} K^m_t(x, y) \chi_{t, y} \left( t, y \right) t^2 (-\Delta) e^{t^2 \Delta} f(y) dw(y) \right| dt.$$ 

where $K^m_t(x, y)$ is the integral kernel of the operator $(-t^2 \Delta)^m \Phi_t \Phi_t$. Recall that

$$|K^m_t(x, y)| \leq Cw(B(x, t))^{-1}$$

and

$$K^m_t(x, y) = 0 \text{ for } d(x, y) > t/2$$

(see (10.9) and Corollary 3.10). Thus,

$$|\Delta^m b_{[n,j]}(x)| \leq C(\lambda_{[n,j]})^{-1} 2^{j+1} \left| \int_0^{r_{[n,j]}} t^{2M-2m} |K^m_t(x, y)| dw(y) \right| dt \ dt$$

(11.15)

$$\leq C(\lambda_{[n,j]})^{-1} 2^{j+1} \left| \int_0^{r_{[n,j]}} t^{2M-2m} \frac{dt}{t} \right|$$

$$= C(\lambda_{[n,j]})^{-1} 2^{j} \left( r_{[n,j]} \right)^{2M-2m}$$

$$= Cw(Q_{[n,j]})^{-1} \left( r_{[n,j]} \right)^{2M-2m}.$$

**Step 8. Key lemma.** It remains to estimate

$$a_{[n,j]}(x) = (\lambda_{[n,j]})^{-1} c \left| \int_0^{\infty} \int_0^{\infty} \chi_{t, y} \left( t, y \right) \left( t^2 (-\Delta) e^{t^2 \Delta} f(y) \right) dy \right| dt \ dt.$$ 

Let $E_{[n,j]} = \bigcup_{i=1}^n Q_{i, j}$. Then

$$\chi_{t, y} \left( t, y \right) = \chi_{\hat{\Omega}_j} \left( t, y \right) \chi_{R(E_{[n,j]})} \left( t, y \right) \chi_{R(E_{[n-1,j]})} \left( t, y \right) \chi_{R(E_{[n-2,j]})} \left( t, y \right) \chi_{R(E_{[n-3,j]})} \left( t, y \right) \chi_{R(E_{[n-4,j]})} \left( t, y \right) \chi_{R(E_{[n-5,j]})} \left( t, y \right) \chi_{R(E_{[n-6,j]})} \left( t, y \right) \chi_{R(E_{[n-7,j]})} \left( t, y \right) \chi_{R(E_{[n-8,j]})} \left( t, y \right) \chi_{R(E_{[n-9,j]})} \left( t, y \right) \chi_{R(E_{[n-10,j]})} \left( t, y \right)$$

(11.16)

The following lemma (see [27, Lemma 4.2]) plays a crucial role in the remaining part of the proof of Theorem 11.4.

**Lemma 11.17.** For every $x \in \Omega_j$ and every function $\chi_s$, $s = 1, 2, 3, 4$, there are numbers $0 < \delta_s \leq \omega_s$ such that $\omega_s \leq 3\delta_s$ and

either $\Psi_t(x, y) \chi_s(t, y) = 0$ for every $0 < t < \delta_s$ or $\Psi_t(x, y) \chi_s(t, y) = \Psi_t(x, y)$ for every $0 < t < \delta_s$ 

and
either $\Psi_t(x,y)\chi_s(t,y) = 0$ for every $t > \omega_s$ or $\Psi_t(x,y)\chi_s(t,y) = \Psi_t(x,y)$ for every $t > \omega_s$.

**Proof.** For the reader’s convenience, we include a short proof along the lines of [27].
Fix $t > 0$ and define $\chi'_1(y) = \chi_{[4t,\infty)}(d(y,\Omega^c_j))$, $\chi'_2(y) = \chi_{(-\infty,4t)}(d(y,\Omega^c_{j+1}))$, $\chi'_3(y) = \chi_{(-\infty,2t)}(d(y,E\{n,j\}))$, $\chi'_4(y) = \chi_{(2t,\infty)}(d(y,E\{n-1,j\}))$. Clearly, $\chi'_s(y) = \chi_s(t,y)$ for $s = 1, 2, 3, 4$. If $d(x,y) \geq t$, then $\Psi_t(x,y) = \Psi_t(x,y)\chi_s(t,y) = 0$. Therefore, to finish the proof, we assume that $d(x,y) < t$. Then

$$-t + d(A, x) < d(A, y) < t + d(A, x) \text{ for } A = \Omega^c_j, \Omega^c_{j+1}, E\{n,j\}, E\{n-1,j\}.$$ 

We are in a position to define consecutively $\delta_s$ and $\omega_s$.

1. If $d(x, \Omega^c_j) < 3t$ or $d(x, \Omega^c_{j+1}) > 5t$, then $\chi'_1(y) = 0$ and $\chi'_1(y) = 1$ respectively, so we put $\delta_1 = \frac{1}{3}d(x, \Omega^c_j)$ and $\omega_1 = \frac{1}{3}d(x, \Omega^c_{j+1})$.

2. If $d(x, \Omega^c_{j+1}) < 3t$ or $d(x, \Omega^c_{j+1}) > 5t$, then $\chi'_2(y) = 1$ and $\chi'_2(y) = 0$ respectively. Hence we set $\delta_2 = \frac{1}{3}d(x, \Omega^c_{j+1})$ and $\omega_2 = \frac{1}{3}d(x, \Omega^c_{j+1})$ if $d(x, \Omega^c_{j+1}) \neq 0$, $\delta_2 = \omega_2 = \delta_1$ otherwise.

3. If $d(x, E\{n,j\}) < t$ or $d(x, E\{n-1,j\}) > 3t$, then $\chi'_3(y) = 1$ and $\chi'_3(y) = 0$ respectively.

Thus we put $\delta_3 = \frac{1}{3}d(x, E\{n,j\})$ and $\omega_3 = d(x, E\{n,j\})$ if $d(x, E\{n,j\}) \neq 0$, $\delta_3 = \omega_3 = \delta_1$ otherwise.

4. If $d(x, E\{n-1,j\}) < t$ or $d(x, E\{n-1,j\}) > 3t$, then $\chi'_4(y) = 0$ and $\chi'_4(y) = 1$ respectively, so we put $\delta_4 = \frac{1}{3}d(x, E\{n-1,j\})$ and $\omega_4 = d(x, E\{n-1,j\})$ if $d(x, E\{n-1,j\}) \neq 0$, $\delta_4 = \omega_4 = \delta_1$ otherwise.

We finish Step 8 by the remark (see Case 1 of the proof of the lemma) that if $t > \omega_1 > 0$ then

$$\Psi_t(x,y)\chi_{T\{n,j\}}(t,y) = 0.$$

**Step 9. Estimates for $a_{\{n,j\}}$.** We shall prove that

$$(11.18) \quad |a_{\{n,j\}}(x)| \leq C w(Q_{\{n,j\}})^{-1}.$$ 

Fix $x \in \Omega_j$. Recall that supp $a_{\{n,j\}} \subset \Omega_j$. Let $J = \bigcup_{s=1}^{4}[\delta_s, \omega_s]$, $I = (0, \infty) \setminus J$, where $\delta_s, \omega_s$ are from Lemma 11.17. Obviously, $I = (a_1, b_1) \cup \ldots \cup (a_m, b_m)$, where $m \leq 5$, $a_1 = 0$, $b_m = \infty$, and $(a_t, b_t)$ are connected disjoint components of $I$. Clearly,

$$|a_{\{n,j\}}(x)| \leq \sum_{s=1}^{4}(\lambda_{n,j})^{-1}c \int_{\delta_s}^{\omega_s} \int \Psi_t(x,y)\chi_{T\{n,j\}}(t,y)(t^2(-\Delta)e^{t^2\Delta}f)(y) \, dw(y) \frac{dt}{t}$$

$$+ \sum_{s=1}^{m}(\lambda_{n,j})^{-1}c \int_{a_s}^{b_s} \int \Psi_t(x,y)\chi_{T\{n,j\}}(t,y)(t^2(-\Delta)e^{t^2\Delta}f)(y) \, dw(y) \frac{dt}{t}. $$

Consider the integral over $[\delta_s, \omega_s]$. Take $t \in [\delta_s, \omega_s]$ and $y$ such that the integrand $|\Psi_t(x,y)\chi_{T\{n,j\}}(t,y)(t^2(-\Delta)e^{t^2\Delta}f)(y)| \neq 0$. Then $(t, y) \notin \Omega_{j+1}$. Thus, there is $x'$ such
that \( d(y, x') < 4t \) and \( x' \notin \Omega_{j+1} \), which means that \( Mf(x') \leq 2^{j+1} \). Consequently, 
\[ |t^2(-\Delta)e^{t^2\Delta}f(y)| \leq 2^{j+1}. \]
Hence,
\[
(\lambda_{n,j})^{-1} c \int_{\delta_a}^{\omega_s} \left| \Psi_t(x, y) \chi_{T_{n,j}}(t, y)(t^2(-\Delta)e^{t^2\Delta}f(y))\right| dw(y) \frac{dt}{t} \\
\leq (\lambda_{n,j})^{-1} 2^{j+1} c \int_{\delta_a}^{\omega_s} \left| \Psi_t(x, y)\right| dw(y) \frac{dt}{t} \\
\leq C(\lambda_{n,j})^{-1} 2^{j+1} c \int_{\delta_a}^{\omega_s} \frac{dt}{t} \\
\leq Cw(Q_{n,j})^{-1},
\]
because \( 0 < \omega_s \leq 3\delta_s \).

We turn to estimate the integrals over \([a_s, b_s]\). Assume that
\[
(\lambda_{n,j})^{-1} c \int_{a_s}^{b_s} \left| \Psi_t(x, y) \chi_{T_{n,j}}(t, y)(t^2(-\Delta)e^{t^2\Delta}f(y))\right| dw(y) \frac{dt}{t} > 0
\]
By Lemma 11.17 for fixed \( x \in \Omega_j \) and \( s \in \{1, 2, \ldots, m\} \) either \( \chi_{T_{n,j}}(t, y) \equiv 0 \) for all \( t \in [a_s, b_s] \) and \( d(x, y) < t \) or \( \chi_{T_{n,j}}(t, y) \equiv 1 \) for all \( t \in [a_s, b_s] \) and \( d(x, y) < t \). So the letter holds. This gives that for every \( t \in [a_s, b_s] \) and \( y \) such that \( d(x, y) < t \) we have that \( (t, y) \notin \tilde{\Omega}_{j+1} \). So there is \( x' \) (which depends on \( (t, y) \)) such that \( d(y, x') < 4t \) and \( Mf(x') < 2^{j+1} \). Note that \( d(x, x') < d(x, y) + d(y, x') < 5t \). Consequently, for every \( t \in [a_s, b_s] \) we have
\[
2^{j+1} \geq Mf(x') \geq \sup_{d(x', y) < 5t} |\Xi_t f(z)| \geq |\Xi_t f(x)|.
\]
Finally, in our case
\[
(\lambda_{n,j})^{-1} c \int_{a_s}^{b_s} \left| \Psi_t(x, y) \chi_{T_{n,j}}(t, y)(t^2(-\Delta)e^{t^2\Delta}f(y))\right| dw(y) \frac{dt}{t} \\
= (\lambda_{n,j})^{-1} c \int_{a_s}^{b_s} \left| \Psi_t(x, y)(t^2(-\Delta)e^{t^2\Delta}f(y))\right| dw(y) \frac{dt}{t} \\
= (\lambda_{n,j})^{-1} c |\Xi_{a_s} f(x) - \Xi_{b_s} f(x)| \\
\leq Cw(Q_{n,j})^{-1},
\]
where in the last equality we have used (11.5). The estimates (11.19) and (11.20) give (11.18). Recall that \( w(Q_{n,j}) \sim w(B(x_{n,j}, 7r_{n,j}/2)) \). Hence, from (11.18), (11.15), (11.12), and (11.13) we deduce Step 5. The proof of Theorem 11.4 is complete. \( \square \)

The next lemma will help us to remove the extra assumption that \( f \in L^2(dw) \).

**Lemma 11.21.** Assume that \( f \in H^1_{\text{max}, p} \). Then \( P_t f \in L^2(dw) \) for every \( t > 0 \) and
\[
(11.22) \quad \lim_{t \to 0} \|P_t f - f\|_{H^1_{\text{max}, p}} = 0.
\]
\textbf{Proof.} Proposition \ref{prop:regularity} implies that $P_tf \in L^2(dw)$. To prove \eqref{eq:proof1} we follow, e.g., \cite[proof of (6.5)]{10}.

First observe that there is a constant $C > 0$ such that for every $A > 0$ and $t > 0$ we have
\begin{equation}
\left\| \sup_{\|x-y\| < s, s > At} |P_{t+s}f(y) - P_sf(y)| \right\|_{L^1(dw(x))} \leq CA^{-1} \|f\|_{L^1(dw)}.
\end{equation}

To see \eqref{eq:proof1} fix $z \in \mathbb{R}^N$. For $s > At$, thanks to \eqref{eq:regularity}, we have
\begin{align*}
|p_{s+t}(y, z) - p_s(y, z)| &= \left| \int_0^t \partial_u p_{s+u}(y, z) \, du \right| \\
&\leq C \int_0^t \frac{1}{u + s + d(y, z)} w(B(z, s + u + d(y, z)))^{-1} \, du \\
&\leq C \int_0^t \frac{1}{s + d(y, z)} w(B(z, s + d(y, z)))^{-1} \, du \\
&\leq \frac{C}{A} \frac{s}{s + d(y, z)} w(B(z, s + d(x, z)))^{-1}.
\end{align*}

Since $s + d(x, z) \leq s + d(x, y) + d(y, z) \leq s + \|x - y\| + d(y, z) \leq 2(s + d(y, z))$, we obtain
\begin{equation}
\sup_{\|x-y\| < s} |p_{s+t}(y, z) - p_s(y, z)| \leq \frac{C}{A} \frac{s}{s + d(x, z)} w(B(z, s + d(x, z)))^{-1},
\end{equation}

which implies \eqref{eq:proof1}.

In order to finish the proof of \eqref{eq:proof1} assume that $f \in H^1_{\text{max}, P}$. Then
\begin{align*}
\|P_tf - f\|_{H^1_{\text{max}, P}} &\leq \left\| \sup_{\|x-y\| < s, s > At} |P_{t+s}f(y) - P_sf(y)| \right\|_{L^1(dw(x))} \\
&+ \left\| \sup_{\|x-y\| < s, s \leq At} |P_{t+s}f(y) - P_sf(y)| \right\|_{L^1(dw(x))} \\
&\leq CA^{-1} \|f\|_{L^1(dw)} + \sup_{\|x-y\| < s, s \leq At} |P_{s+t}f(y) - f(x)| \left\| \sup_{\|x-y\| < s, s \leq At} |P_{s+t}f(y) - f(x)| \right\|_{L^1(dw(x))} \\
&+ \left\| \sup_{\|x-y\| < s, s \leq At} |P sf(y) - f(x)| \right\|_{L^1(dw(x))} \\
&\leq CA^{-1} \|f\|_{L^1(dw)} + \sup_{\|x-y\| < s, s \leq (A+1)t} |P sf(y) - f(x)| \left\| \sup_{\|x-y\| < s, s \leq (A+1)t} |P sf(y) - f(x)| \right\|_{L^1(dw(x))}.
\end{align*}

Fix $\varepsilon > 0$ and take $A = C\varepsilon^{-1}$. Corollary \ref{cor:convergence} implies
\begin{align*}
\lim_{t \to 0} \sup_{\|x-y\| < s, s \leq (A+1)t} |P sf(y) - f(x)| = 0 
\end{align*}
for almost every $x \in \mathbb{R}^N$.

Since $\sup_{\|x-y\| < s, s \leq (A+1)t} |P sf(y) - f(x)| \leq 2M_P f(x) \in L^1(dw(x))$, the proof is complete by applying the Lebesgue dominated convergence theorem. \hfill \Box
Having Lemma 11.21 we are in a position to complete the proof of the atomic decomposition of $H^1_{\max, P}$ functions. This is stated in the theorem below.

**Theorem 11.25.** There is a constant $C > 0$ such that every function $f \in H^1_{\max, P}$ can be written as

$$f = \sum \lambda_j a_j,$$

where $a_j$ are $(1, \infty, M)$-atoms, $\sum |\lambda_j| \leq C \|M_P f\|_{L^1(dw)}$.

**Proof.** Take a sequence $t_n \to 0$, $n = 0, 1, \ldots$, such that $\|P_{t_n} f\|_{H^1_{\max, P}} \leq 2 \|f\|_{H^1_{\max, P}}$, $\|P_{t_{n+1}} f - P_{t_n} f\|_{H^1_{\max, P}} \leq 2^{-n} \|f\|_{H^1_{\max, P}}$. Then $f = f_0 + \sum_{n=1}^\infty (P_{t_n} f - P_{t_{n-1}} f) = g_0 + \sum_{n=1}^\infty g_n$, with convergence in $L^1(dw)$. The functions $g_n \in L^2(dw) \cap H^1_{\max, P}$, so, by Theorem 11.4 they admit atomic decompositions into $(1, \infty, M)$-atoms with the required control of their atomic norms. \hfill $\Box$

The following theorem is a direct consequence of Lemma 11.2 and Theorem 11.25.

**Theorem 11.26.** There is a constant $C > 0$ such that every element $f \in H^1_{\max, H}$ can be written as

$$f = \sum \lambda_j a_j$$

where $a_j$ are $(1, \infty, M)$-atoms, $\sum |\lambda_j| \leq C \|M_H f\|_{L^1(dw)}$.

We are in position to complete the proof of Theorem 2.5, by proving the following proposition, which is the converse to Proposition 7.12.

**Proposition 11.27.** Assume that $u_0$ is $\mathcal{L}$-harmonic and satisfies $u_0^* \in L^1(dw)$. Then there is a system $u = (u_0, u_1, \ldots, u_N) \in \mathcal{H}_{\mathcal{L}}$ such that $\|u\|_{\mathcal{H}_{\mathcal{L}}} \leq C \|u_0^*\|_{L^1(dw)}$.

**Proof.** By Theorem 7.8 we have $u_0(t, x) = P_t f_0(x)$, where $f_0 \in L^1(dw)$. So $f_0 \in H^1_{\max, P}$ and $\|f_0\|_{H^1_{\max, P}} = \|u_0^*\|_{L^1(dw)}$. Using Theorem 11.25 and then (9.1) we obtain that $f_0 \in H^1_{\Delta}$ and $\|f_0\|_{H^1_{\Delta}} \leq C \|u_0^*\|_{L^1(dw)}$. \hfill $\Box$

12. **Inclusion** $H^1_{(1,q,M)} \subset H^1_{\max, H}$

In this section we shall prove that for every integer $M \geq 1$ and every $1 < q \leq \infty$, we have $H^1_{(1,q,M)} \subset H^1_{\max, H}$ and

$$\|f\|_{H^1_{\max, H}} \leq C_{M,q} \|f\|_{H^1_{(1,q,M)}}.$$ 

It suffices to establish that there is a constant $C_{M,q} > 0$ such that

$$\|a\|_{H^1_{\max, H}} \leq C_{M,q}$$

for every $a$ being $(1, q, M)$-atom. Since every $(1, q, M)$-atom is automatically $(1, q, 1)$-atom, it is enough to consider $M = 1$ only.

Assume that $a$ is a $(1, q, 1)$-atom associated with a set $B = \bigcup_{\sigma \in G} B(\sigma(y_0), r)$. Then there is a function $b \in \mathcal{D}^{\Delta}(\Delta)$ such that $a = \Delta b$, supp $\Delta_j b \subset B$, $\|\Delta_j b\|_{L^q(dw)} \leq r^{2-2j} w(B)^{\frac{1}{q}-1}$, $j = 0, 1$. Set $u(t, x) = e^{t\Delta} a(x)$. Observe that

$$\|u^*\|_{L^q(dw)} \leq C_q \|a\|_{L^q(dw)} \leq w(B)^{\frac{1}{q}-1}$$
(see (2.6) for the definition of \( u^* \)). Thus, by the doubling property of the measure \( dw(x) \) and the Hölder inequality,

\[
\int_{d(x,y_0) \leq 8r} u^*(x) \, dw(x) \leq C'_q.
\]

We turn to estimate \( u^*(x) \) on \( d(x,y_0) > 8r \). Clearly,

\[
\begin{align*}
   u^*(x) & \leq \sup_{0 < t < d(x,y_0)/4, d(x',x) < t} |e^{t^2 \Delta} b(x')| + \sup_{t > d(x,y_0)/4, d(x',x) < t} |e^{t^2 \Delta} b(x')| \\
   &= J_1(x) + J_2(x).
\end{align*}
\]

Recall that \( \|b\|_{L^1(dw)} \leq r^2 \) and note that

\[
e^{t^2 \Delta} = \Delta e^{t^2 \Delta} = \frac{d}{ds} e^{s \Delta} \big|_{s=t^2}.
\]

To deal with \( J_1 \) we note that if \( d(x',x) < t \leq d(x,x_0)/4, d(x,y_0) > 4r \), and \( d(y,y_0) < r \), then \( d(x',y) \sim d(x,y_0) \). So, using (4.4), we have

\[
   \left| \frac{d}{ds} h_s(x',y) \right|_{s=t^2} \leq \frac{C}{t^2 w(B(y_0, d(y_0,x))} e^{-t^2 d(y_0,x)^2/t^2}.
\]

Hence,

\[
   J_1(x) \lesssim w(B(y_0, d(x,y_0)))^{-1} \frac{r^2}{d(x,y_0)^2}.
\]

In order to estimate \( J_2 \), we observe from (4.4) that for \( t > d(x,y) \) and \( d(y,y_0) < r < t \) we have

\[
   \left| \frac{d}{ds} h_s(x',y) \right|_{s=t^2} \leq \frac{C}{t^2 w(B(y_0, d(y_0,x))}
\]

Consequently,

\[
   J_2(x) \lesssim w(B(y_0, d(x,y_0)))^{-1} \frac{r^2}{d(x,y_0)^2}.
\]

Now

\[
\int_{d(x,y_0) > 8r} u^*(x) \, dw(x) \lesssim \sum_{j=3}^{\infty} \int_{2^{j+1}r < d(x,y_0) \leq 2^j r} \frac{r^2}{w(B(y_0, d(x,y_0))) d(x,y_0)^2} \, dw(x)
\]

\[
\lesssim \sum_{j=3}^{\infty} 2^{-2j} = C.
\]

13. Square function characterization

In this section we prove Theorem 2.9. More precisely we show that the atomic Hardy space \( H^1_{(1,2,M)} \) coincides with the Hardy space defined by the square function (2.8) with \( Q_t = t \sqrt{-\Delta} e^{-t \sqrt{-\Delta}} \). This is achieved by mimicking arguments in [15]. The proof for \( Q_t = t^2 (-\Delta) e^{t^2 \Delta} \) is similar.

**Tent spaces** \( T^p_2 \) **on spaces of homogeneous type.** The square function characterization of the Hardy space \( H^1_{(1,2,M)} \) can be related with the so called tent space \( T^1_2 \).
The tent spaces on Euclidean spaces were introduced in [6] and then extended on spaces of homogeneous type (see, e.g., [23]). For more details we refer the reader to [25].

For a measurable function $F(t, x)$ on $(0, \infty) \times \mathbb{R}^N$ let

$$ AF(x) := \left( \int_0^\infty \int_{\|y-x\| < t} |F(t, y)|^2 \frac{dw(y)}{w(B(x, t))} dt \right)^{1/2}. $$

**Definition 13.1.** For $1 \leq p < \infty$ the tent space $T^p_2$ is defined to be

$$ T^p_2 = \{ F : \| F \|_{T^p_2} := \| AF \|_{L^p(dw)} < \infty \}. $$

Clearly, by the doubling property,

$$ \| F \|_{T^2_2}^2 = \| AF \|_{L^2(dw)}^2 \sim \int_0^\infty \int_{\mathbb{R}^N} |F(t, y)|^2 \frac{dw(y)dt}{t}. \tag{13.2} $$

**Remark 13.3.** By (10.8) and (13.2) the operator $\pi_\Phi$ maps continuously the space $T^2_2$ into $L^2(dw)$.

Furthermore, by (10.7), if $F(t, x) = Q_tf(x)$ for $f \in L^2(dw)$, then

$$ \| F \|_{T^2_2} = \| Sf \|_{L^2(dw)} \sim \| f \|_{L^2(dw)}, $$

and $f = c\pi_\Phi(F)$.

The tent space $T^1_2$ on the space of homogenous type admits the following atomic decomposition (see, e.g., [23]).

**Definition 13.4.** A measurable function $A(t, x)$ is a $T^1_2$-atom if there is a ball $B \subset \mathbb{R}^N$ such that

- $\text{supp } A \subset \mathcal{B}$
- $\int_{(0, \infty) \times \mathbb{R}^N} |A(t, x)|^2 dw(x) \frac{dt}{w(B)} \leq w(B)^{-1}$.

A function $F$ belongs to $T^1_2$ if and only if there are sequences $A_j$ of $T^1_2$-atoms and $\lambda_j \in \mathbb{C}$ such that

$$ \sum_j \lambda_j A_j = F, \quad \sum_j |\lambda_j| \sim \| F \|_{T^2_2}, $$

where the convergence is in $T^1_2$ norm and a.e.

The Hölder inequality immediately gives that there is a constant $C > 0$ such that for every function $A(t, x)$ being a $T^1_2$-atom one has

$$ \| A \|_{T^2_2} \leq C. $$

Observe that for $f \in L^1(dw)$ the function $F(t, x) = Q_tf(x)$ is well defined. Moreover, $AF(x) = Sf(x)$ and $\| Sf \|_{L^1(dw)} = \| F \|_{T^2_2}$.

**Remark 13.5.** According to the proof of atomic decomposition of $T^1_2$ presented in [23], the function $\lambda_j A_j$ can be taken of the form $\lambda_j A_j(x, t) = \chi_{S_j}(x, t)$, where $S_j$ are disjoint, $\mathbb{R}^N_{x,t} = \bigcup S_j$, and $S_j$ is contained in a tent $B_j$.

So, if $F \in T^1_2 \cap T^2_2$, then $F$ can be decomposed into atoms such that $F(t, x) = \sum_j \lambda_j A_j(x, t)$ and the convergence is in $T^1_2$, $T^2_2$, and pointwise.
Lemma 13.6. The map \((P_s F)(t, x) = \int p_s(x, y) F(t, y) \, dw(y)\) is bounded on \(T_2^1\). Moreover, there is a constant \(C > 0\) independent of \(s > 0\) such that \(\|P_s F\|_{T_2^1} \leq C \|F\|_{T_2^1}\).

Proof. Let \(F(t, x) = \sum_j \lambda_j A_j(t, x)\) be an atomic decomposition of \(F \in T_2^1\) as described above. Since \(p_s(x, y) \geq 0\), it suffices to prove that there is a constant \(C > 0\) such that

\[
\|P_s|A|\|_{T_2^1} \leq C
\]

for every atom \(A\) of \(T_2^1\). To this end let \(B = B(x_0, r)\) be a ball associated with \(A\). Obviously, \(P_s|A|[t, t'] = 0\) for \(t > r\).

Case 1: \(s > r\). Then, by (5.5) and the Hölder inequality,

\[
P_s|A|[t, t'] \leq \frac{Cs}{s + d(x_0, x')} \left( \frac{w(B(x_0, r))^{1/2}}{w(B(x_0, s + d(x_0, x')))} \right) \left( \int |A(t, y)|^2 \, dw(y) \right)^{1/2}.
\]

If \(\|x - x'\| < t \leq r\), then \(s + d(x_0, x') \sim s + d(x_0, x)\), because, by our assumption, \(s > r\). Hence,

\[
\|P_s|A|\|_{T_2^1} \leq C \int \frac{s}{s + d(x_0, x)} \left( \frac{w(B(x_0, r))^{1/2}}{w(B(x_0, s + d(x_0, x)))} \right) \left( \int_0^r \int_{\|x - x'\| < t} \int |A(t, y)|^2 \, dw(y) \, \frac{dw(x')}{w(B(x, t))} \right)^{1/2} \, dw(x)
\]

where to get the second to last inequality we first integrated with respect to \(dw(x')\) and then used the definition of \(T_2^1\)-atom.

Case 2: \(s \leq r\). Recall that \(P_s\) is a contraction on \(L^2(dw)\). Hence,

\[
\|AP_s|A|\|_{L^1(\mathcal{O}(B(x_0, 4r)), dw)} \leq Cw(B(x_0, r))^{1/2} \|AP_s|A|\|_{L^2(dw)} \leq Cw(B(x_0, r))^{1/2} \|P_s|A|\|_{T_2^1} \leq Cw(B(x_0, r))^{1/2} \|A\|_{T_2^1} \leq C.
\]

If \(d(x, x_0) > 4r, \|x' - x\| < t < r\), and \(\|x_0 - y\| < r\), then \(s + d(x', y) \sim s + d(x, x_0)\). Now we proceed as in Case 1 to get the required bound on \(\mathcal{O}(B(x_0, 4r))\).

Lemma 13.8. The family \(P_s\) forms approximate of identity in \(T_2^1\), that is,

\[
\lim_{s \to 0} \|P_s F - F\|_{T_2^1} = 0.
\]

Proof. According to Lemma 13.6, it suffices to establish that for every \(A\) being a \(T_2^1\)-atom we have

\[
\lim_{s \to 0} \|P_s A - A\|_{T_2^1} = \lim_{s \to 0} \|A(P_s A - A)\|_{L^1(dw)} = 0.
\]

Let \(A\) be such an atom and let \(B = B(x_0, r)\) be its associated ball. To prove (13.9) it suffices to consider \(0 < s < r\).
If \( d(x, x_0) > 4r, \|y - x_0\| < r, \) and \( \|x - x'\| < t < r, \) then \( s + d(x', y) \sim d(x, x_0), \) so
\[
|P_sA(t, x')| \leq \frac{Cs}{s + d(x_0, x)} w(B(x_0, r))^{1/2} \left( \int |A(t, y)|^2 dw(y) \right)^{1/2}.
\]
Since \( \text{supp } A \cap \{(t, x'): \|x' - x\| < t < r\} = \emptyset, \) we have
\[
|A(P_sA - A)(x)| = |A(P_sA)(x)| \leq \frac{Cs}{s + d(x_0, x)} w(B(x_0, r))^{1/2}.
\]
Hence,
\[
\lim_{s \to 0} \int_{d(x, x_0) > 4r} |A(P_sA - A)(x)| dw(x) = 0.
\]
We now turn to estimate \( \|A(P_sA - A)\|_{L^1(O(B(x_0, 4r)), dw)} \). Observe that
\[
|(P_sA - A)(t, x')| \leq 2M_P A(t, x') \quad \text{and} \quad \|M_P A(t, x')\|_{L^2(dw(x'))} \leq C\|A(t, x')\|_{L^2(dw(x'))}.
\]
Moreover, \( \lim_{s \to 0} \|P_sA(t, x') - A(t, x')\|_{L^2(dw(x'))} = 0 \) for almost every \( t > 0 \). Therefore, applying the Hölder inequality and (13.2), we have
\[
\limsup_{s \to 0} \|A(P_sA - A)\|_{L^1(O(B(x_0, 4r)))} \leq \limsup_{s \to 0} Cw(B)^{1/2} \|A(P_sA - A)\|_{L^2(O(B(x_0, 4r)))} \leq \limsup_{s \to 0} Cw(B)^{1/2} \left( \int_0^r \int |P_sA(t, x) - A(t, x)|^2 \frac{dw(x)}{dt} dt \right)^{1/2} = 0,
\]
where in the last equality we have used the Lebesgue dominated convergence theorem.

Lemma 13.10. For every positive integer \( M \) there is a constant \( C_M > 0 \) such that for every \( a(x) \) being a \((1, 2, M)\)-atom if \( F(t, x) = Q_t a(x) \), then
\[
\|F(t, x)\|_{T^1} \leq C_M.
\]
Proof. Let \( a \) be a \((1, 2, M)\)-atom, \( M \geq 1 \), associated with a ball \( B = B(x_0, r) \). By definition \( a = \Delta^M b \) with \( \Delta^\ell b \) (for \( \ell = 0, 1, \ldots, M \)) satisfying relevant support and size conditions (see Definition 2.12). By the Hölder inequality,
\[
\|S a\|_{L^1(O(B))} \lesssim \|S a\|_{L^2(O(B))} w(O(8B))^{1/2} \lesssim 1.
\]
If \( d(x, x_0) > 8r \) then choose \( n \geq 3 \) such that \( 2^n r \leq d(x, x_0) < 2^{n+1} r \) and split the integral as below
\[
S a(x)^2 = \int \int_{t > \|x - y\|} |Q_t a(y)|^2 w(B(y, t))^{-1} w(y) dt \frac{dt}{t} = \int_{2^n r/4}^{2^{n+1} r/4} \int_{t > \|x - y\|} + \int_{t > 2^n r/4}^{\infty} \int_{t > \|x - y\|} = I_1 + I_2.
\]
Define \( a_1 = \Delta^{M-1} b \). Then by the definition of the atom \( \|a_1\|_{L^1(w)} \leq r^2 \). Note that
\[
Q_t(a) = Q_t(\Delta a_1) = (\Delta Q_t)(a_1) = t(\partial_t Q_t)^3(a_1).
\]
Estimation for $I_1$. If $z \in \mathcal{O}(B)$ and $\|x - y\| < t \leq 2^n r/4$, then $2^n r \lesssim d(z, y)$. Therefore, thanks to (5.5) and (5.8) with $m = 3$, we have

$$|Q_t a(y)|^2 = \left| \int t(\partial_t^3)(p_t(y, z))a_1(z) \, dw(z) \right|^2 \lesssim \left( \int d(z, y)^{-2} \frac{t}{t + d(z, y)} V(z, y, t + d(z, y))^{-1} |a_1(z)| \, dw(z) \right)^2 \lesssim (2^n r)^{-4} t^2 \frac{t}{(2^n r)^2} w(B(x_0, 2^n r))^{-2} \|a_1\|_{L^1(dw)}^2.$$ 

Consequently,

$$I_1 \lesssim \left( \int_0^{2^n r} t \, dt \right) w(B(x_0, 2^n r))^{-2} \|a_1\|_{L^1(dw)}^2 (2^n r)^{-4} (2^n r)^{-2} \lesssim 2^{-4n} w(B(x_0, 2^n r))^{-2}.$$

Estimation for $I_2$. In this case $t \geq 2^n r/4$, so thanks to (5.8) with $m = 3$ we have

$$|Q_t a(y)|^2 = \left( \int t(\partial_t^3)(p_t(y, z))a_1(z) \, dw(z) \right)^2 \lesssim \left( \int t^{-2} \frac{t}{t + d(z, y)} V(z, y, t + d(z, y))^{-1} |a_1(z)| \, dw(z) \right)^2 \lesssim t^{-4} w(B(x_0, 2^n r))^{-2} \|a_1\|_{L^1(dw)}^2.$$ 

Consequently,

$$I_2 \lesssim \left( \int_{2^n r/4}^{\infty} t^{-5} \, dt \right) w(B(x_0, 2^n r))^{-2} \|a_1\|_{L^1(dw)}^2 \lesssim 2^{-4n} w(B(x_0, 2^n r))^{-2}.$$

Finally,

$$\|Sa\|_{L^1(\mathcal{O}(B)^c)} \lesssim \sum_{n \geq 3} \int_{2^n r < d(x, x_0) \leq 2^{n+1} r} 2^{-2n} w(B(x_0, 2^n r))^{-1} \, dw(x) \lesssim 1.$$

\[\square\]

Proposition 13.11. Let $M$ be a positive integer. Assume that for $f \in L^1(dw)$ the function $F(t, x) = Q_t f(x)$ belongs to $T^1_2$. Then there are $\lambda_j \in \mathbb{C}$ and $a_j$ being $(1, 2, M)$-atoms such that

$$f = \sum_j \lambda_j a_j,$$

and

$$\sum_j |\lambda_j| \leq C \|F\|_{T^1_2}.$$ 

The constant $C$ depends on $M$ but is independent of $f$. 

Proof. We start our proof under the additional assumption \( f \in L^2(dw) \). Then \( F(t, x) = Q_t f(x) \in T^1_2 \cap T^2_2 \). The proof in this case is the same as that of [15, Theorem 4.1]. The only difference is to control support of functions \( \Delta^* b_j \). For the convenience of the reader we provide its sketch.

Let \( F = \sum_j \lambda_j A_j \) be a \( T^1_2 \) atomic decomposition of the function \( Q_t f(x) \) as it is described in Remark 13.5. In particular, \( \sum_j |\lambda_j| \leq C \| S f \|_{L^1(dw)} \). Let \( \Psi \) be chosen such that \( \int_0^\infty \Psi_t Q_t \frac{dt}{t} \) forms a Calderón reproducing formula, with \( \Psi = \Delta^{M+1} \Psi^{(1)} \), where \( \Psi^{(1)} \) is a radial \( C^\infty \) function supported by \( B(0, 1/4) \). By Remark 13.3 we have

\[
(13.12) \quad f = \pi_\Psi F = \sum_j \lambda_j \pi_\Psi A_j
\]

and the series converges in \( L^2(dw) \). Let \( B_j = B(y_j, r_j) \) be a ball associated with \( A_j \). Then \( \text{supp} A_j \subset \mathcal{B}_j \).

Set \( a_j = \pi_\Psi(A_j) = \Delta^M b_j \), where

\[
b_j = \int_0^\infty t^{2M} (t^2 \Delta \Psi^{(1)}_t) A \frac{dt}{t}.
\]

Clearly, \( \text{supp} b_j \subset \mathcal{O}(B(y_j, 2r_j)) \). The same argument as in the proof of Lemma 4.11. in [15] shows that for every \( s = 0, 1, 2, \ldots, M \), the function

\[
b_{j,s} = \Delta^* b_j = \int_0^\infty t^{2M} (\Delta^* t^2 \Psi^{(1)}_t) A \frac{dt}{t}
\]

is supported by \( \mathcal{O}(B(y_j, 2r_j)) \) and its \( L^2(w) \)-norm is bounded by \( r^{2M-2s} w(B_j)^{-1/2} \). Thus \( a_j \) are proportional to \((1, 2, M)\)-atoms. In particular \( \|a_j\|_{L^1(dw)} \leq C \) and, consequently, the series (13.12) converges in \( L^1(dw) \).

To remove the additional assumption \( f \in L^2(dw) \) we use Lemma 13.8 together with the fact that \( P_s f \in L^2(dw) \) for \( f \in L^1(dw) \), and apply the same arguments as those in the proof of Theorem 11.25.
