Abstract

Background: We aimed to investigate the efficacy and safety of atezolizumab plus bevacizumab therapy in patients with unresectable hepatocellular carcinoma (u-HCC) based on whether they had previously received systemic therapy, as well as the association of atezolizumab plus bevacizumab with early alpha-fetoprotein (AFP) response in real-world practice.

Methods: A total of 52 patients with u-HCC were treated with atezolizumab plus bevacizumab between October 2020 and April 2021. The Response Evaluation Criteria in Solid Tumors (RECIST) and modified RECIST were used to evaluate radiological responses.

Results: The patients received atezolizumab plus bevacizumab as 1st-line (n = 23), 2nd-line (n = 16), 3rd-line (n = 6), 4th-line (n = 3), 5th-line (n = 3), or 6th-line (n = 1) therapy. The objective response rate and disease control rate in all patients were 18.4% and 63.2%, respectively. Sixteen patients experienced no adverse events (AEs), whereas 4 patients discontinued therapy due to AEs. The median time to progression (TTP) was significantly longer among patients receiving atezolizumab plus bevacizumab as 1st-line therapy than in patients receiving atezolizumab plus bevacizumab as later-line therapy ($P = 0.02$). Patients with an AFP response (reduction $\geq 20\%$ from baseline) at 6 weeks had a significantly longer TTP than those without an AFP response ($P = 0.02$).

Conclusion: Patients who received atezolizumab plus bevacizumab as 1st-line therapy had better clinical outcome than those who received atezolizumab plus bevacizumab in later lines. The AFP response at 6 weeks could be a predictor of disease progression.

Introduction

Hepatocellular carcinoma (HCC) is the most common primary liver cancer and the fourth most common cause of cancer-related deaths worldwide [1]. HCC is hypervascular, and such angiogenesis is driven by growth factors, such as vascular endothelial growth factor (VEGF). Tyrosine kinase inhibitors targeting VEGF signaling, such as sorafenib [2, 3], regorafenib [4], and lenvatinib [5], have already been approved for the treatment of unresectable HCC (u-HCC) in many countries. Cabozantinib [6] and ramucirumab [7, 8] have been approved as 1st-line agents for u-HCC in Japan. Ramucirumab was approved for patients with a high alpha-fetoprotein (AFP) level ($\geq 400$ ng/mL) in July 2019.

VEGF is also associated with cancer immune evasion. Based on this rationale, the combination of programmed cell death-ligand 1 (PD-L1) (atezolizumab) and VEGF (bevacizumab) pathway inhibition is believed to be the most effective molecular targeted therapy for advanced HCC. In September 2020, atezolizumab plus bevacizumab [9] was approved for patients with u-HCC in Japan and became the recommended 1st-line therapy. In Japan, agents approved for 1st- and 2nd-line therapies can be used for later-line treatment. In this study, we aimed to investigate the efficacy and safety of atezolizumab plus bevacizumab as 1st-line and later-line therapies in real-world practice. Moreover, we analyzed the factors
associated with time to progression (TTP) and the association of atezolizumab plus bevacizumab therapy with the timing of the AFP response and disease progression.

Materials And Methods

Patients

A total of 52 patients with u-HCC received atezolizumab plus bevacizumab therapy at the Musashino Red Cross Hospital between October 2020 and April 2021. Atezolizumab plus bevacizumab therapy was administered after discussions by experts at a tumor board in the institution. HCC diagnosis and evaluation of disease progression were based on guidelines proposed by the Japan Society of Hepatology [10], the American Association for the Study of Liver Disease [11], and the European Association for the Study of the Liver [12]. Written informed consent was obtained from all patients, and the ethics committee of the Musashino Red Cross Hospital approved the study in accordance with the Declaration of Helsinki.

Treatment protocol

Patients received intravenous atezolizumab (1200 mg) plus bevacizumab (15 mg/kg) every 3 weeks until disease progression or unacceptable toxicity. Treatment interruption was performed based on the manufacturer's guidelines. Dynamic computed tomography was performed at baseline, 6–8 weeks after atezolizumab plus bevacizumab administration, and every 6–8 weeks thereafter. Treatment response was reported based on the Response Evaluation Criteria in Solid Tumors (RECIST) [13] and the modified RECIST [14]. The AFP level was also evaluated at baseline and every 3 weeks thereafter. Adverse events (AEs) were evaluated according to the Common Terminology Criteria for Adverse Events version 5.0. To assess changes in liver function, the albumin-bilirubin (ALBI) score [15, 16] was analyzed at baseline and at 3, 6, and 9 weeks after treatment.

Statistical analysis

Overall survival (OS) was measured from the date of atezolizumab plus bevacizumab administration to the date of death from any cause. Patients who were lost to follow-up were censored at their last visit or contact. Patients who were still alive on April 30, 2021 were censored. Progression-free survival (PFS) was measured from the date of atezolizumab plus bevacizumab administration to the date of radiological tumor progression or death from any cause. Data are expressed as median (range) or n (%). Fisher's exact test, Mann–Whitney U test, paired t-test, Kaplan–Meier method, and log-rank test were used for statistical analyses. Statistical significance was set at P < 0.05. Statistical analyses were performed using EZR (Saitama Medical Centre, Jichi Medical University, Shimotsuke, Japan), a graphical user interface for R (The R Foundation for Statistical Computing, Vienna, Austria) [17].
Results

Baseline patient characteristics

The baseline characteristics of the 52 patients are presented in Table 1. Atezolizumab and bevacizumab were administered as 1st-line, 2nd-line, 3rd-line, 4th-line, 5th-line, and 6th-line treatments in 23 (44.2%), 16 (30.8%), 6 (11.5%), 3 (5.8%), 3 (5.8%), and 1 (1.9%) patient, respectively. Among the 16 patients who received atezolizumab plus bevacizumab as 2nd-line treatment, 15 were treated with lenvatinib as 1st-line treatment and 1 patient who had been treated with cytotoxic agents as systemic chemotherapy received ramucirumab as the 1st-line molecular targeted agent. Among the 6 patients who received atezolizumab plus bevacizumab as 3rd-line treatment, 3 were previously treated with lenvatinib and sorafenib, 2 received sorafenib and regorafenib, and 1 received axitinib + avelumab (NCT03289533) and lenvatinib. Among the 3 patients who received atezolizumab plus bevacizumab as 4th-line treatment, 2 were treated with sorafenib, regorafenib, and lenvatinib and 1 received lenvatinib, sorafenib, and regorafenib. Among the 3 patients who received atezolizumab plus bevacizumab as 5th-line treatment, 1 was treated with sorafenib, regorafenib, lenvatinib, and ramucirumab, 1 was treated with sorafenib, cabozantinib, lenvatinib, and ramucirumab, and 1 received lenvatinib, sorafenib, ramucirumab, and regorafenib. The 1 patient who received atezolizumab plus bevacizumab as 6th-line treatment was previously treated with axitinib plus avelumab (NCT03289533), cabozantinib, lenvatinib, ramucirumab, and sorafenib.
Table 1
Baseline characteristics

| Characteristic                                      | Value                  |
|----------------------------------------------------|------------------------|
| n = 52                                              |                        |
| Age (years), median (range)                        | 73 (24–89)             |
| Sex, male/female                                   | 42 (80.8)/ 10 (19.2)   |
| Etiology, HBV/HCV/alcohol/others                   | 10 (19.2)/ 20 (38.5)/ 13 (25.0)/ 9 (17.3) |
| ALBI score, median (range)                         | -2.24 (-3.28 to -1.37) |
| Modified ALBI grade, 1/2a/2b/3                      | 12 (23.1)/ 13 (25.0)/ 26 (50.0)/ 1 (1.9) |
| Child-Pugh class, A/B                              | 48 (92.3)/ 4 (7.7)     |
| ECOG-PS, 0/1                                        | 30 (57.7)/ 22 (42.3)   |
| BCLC stage, A/B/C                                   | 0 (0)/ 29 (55.8)/ 23 (44.2) |
| Major portal invasion, yes/no                      | 6 (11.5)/ 46 (88.5)    |
| Extrahepatic spread, yes/no                        | 17 (32.7)/ 35 (67.3)   |
| Baseline AFP concentration (ng/mL), median (range) | 192.7 (1.6–79739.1)    |

Data are presented as n (%) unless otherwise indicated.

Abbreviations: HBV, hepatitis B virus; HCV, hepatitis C virus; ALBI score, albumin-bilirubin score; ECOG-PS, Eastern Cooperative Oncology Group-Performance status; BCLC, Barcelona Clinic Liver Cancer; AFP, alpha-fetoprotein.

Therapeutic efficacy

At the end of the data cutoff (April 30, 2021), the median duration of follow-up was 126 days (range, 2–187 days). The median number of courses of atezolizumab plus bevacizumab was 4 (range, 1–10). During the observation period, 28 patients continued atezolizumab plus bevacizumab therapy and 24 patients discontinued atezolizumab plus bevacizumab therapy because of progressive disease (PD) (n = 18) or AEs (n = 6). Two patients died from HCC progression, and one patient died of cerebral hemorrhage. The median OS was not reached, and the median PFS was 4.0 months (Figure 1). In 23 patients who received atezolizumab plus bevacizumab as 1st-line treatment, the median OS and PFS were not reached, and the PFS at 3 months was 78.7% (Figure 2).
Radiological evaluation after atezolizumab plus bevacizumab administration was performed in 38 patients. With regard to the best antitumor response according to the RECIST, 1 patient achieved complete response (CR), 6 patients achieved partial response (PR), 17 patients had stable disease (SD), and 14 patients had PD. The objective response rate (ORR) and disease control rate (DCR) were 18.4% and 63.2%, respectively. With regard to the best antitumor response according to the modified RECIST, 1 patient achieved CR, 9 patients achieved PR, 15 patients had SD, and 13 patients had PD. The ORR and DCR were 26.3% and 65.8%, respectively.

Treatment after atezolizumab plus bevacizumab

During the observation period, 22 of 24 patients (91.7%) who discontinued atezolizumab plus bevacizumab received further anticancer therapy (Table 2). The other 2 patients (8.3%) received palliative care. The transition rates to post-treatment among patients receiving atezolizumab plus bevacizumab as 1st-line therapy (n = 4) and those receiving atezolizumab plus bevacizumab as later-line therapy (n = 20) were 100% and 90%, respectively.

| Table 2 |

Changes in liver function during atezolizumab plus bevacizumab therapy

The changes in the ALBI score in 28 patients who received atezolizumab plus bevacizumab for more than 9 weeks are shown in Fig. 3. The median ALBI scores at baseline, 3 weeks, 6 weeks, and 9 weeks were −2.16 (range, −3.28 to −1.59), −2.13 (range, −3.12 to −1.17), −2.16 (range, −3.07 to −1.13), and −1.98 (range, −3.19 to −1.26), respectively. There were no significant differences in the median ALBI scores at baseline and 3 weeks (P = 0.26), at baseline and 6 weeks (P = 0.72), or at baseline and 9 weeks (P = 0.11). Among patients receiving atezolizumab plus bevacizumab as 1st-line treatment (n = 14), the median ALBI scores at baseline, 3 weeks, 6 weeks, and 9 weeks were −2.37 (range, −3.28 to −1.59), −2.35 (range, −3.12 to −1.17), −2.40 (range, −3.07 to −1.13), and −2.40 (range, −3.19 to −1.26), respectively. In
patients receiving atezolizumab plus bevacizumab as 2nd- or later-line therapy (n = 14), the median ALBI scores at baseline, 3 weeks, 6 weeks, and 9 weeks were −2.13 (range, −2.44 to −1.71), −2.10 (range, −3.03 to −1.66), −2.07 (range, −2.73 to −1.60), and −1.92 (range, −3.02 to −1.26), respectively. There were no significant differences in the median ALBI scores at baseline and at 6 weeks or at baseline and at 9 weeks in either group (Fig. 4).

Adverse events during atezolizumab plus bevacizumab therapy

AEs observed during atezolizumab plus bevacizumab therapy are shown in Table 3. Any grade AE was observed in 36 of the 52 patients. The rates of total AEs in patients receiving atezolizumab plus bevacizumab as 1st-line therapy (n = 23) and those receiving atezolizumab plus bevacizumab as 2nd- or later-line therapy (n = 29) were 60.9% and 75.9%, respectively (P = 0.37). When comparing AEs with an incidence of 10% or more, the rates of AEs were 56.5% in patients receiving atezolizumab plus bevacizumab as 1st-line therapy and 75.9% in patients receiving atezolizumab plus bevacizumab as 2nd- or later-line therapy (P = 0.23). No infusion reaction was reported in any patient. During the observation period, six patients discontinued atezolizumab plus bevacizumab therapy owing to AEs, as follows: two patients with transaminase increase, one patient with interstitial pneumonia, one patient with meningitis and transaminase increase, one patient with renal dysfunction, and one patient with gastrointestinal bleeding. Four of the six patients were treated with corticosteroids. The rates of discontinuation due to AEs among patients treated with atezolizumab plus bevacizumab as 1st-line and 2nd- or later-line therapy were 8.7% and 13.8%, respectively (P = 0.68). No AEs other than those reported in the IMbrave150 trial were observed.
Table 3
Adverse events

|                             | Any grade n (%) | Grade ≥ 3 n (%) |
|-----------------------------|-----------------|-----------------|
| Hypertension                | 12 (23.1)       | 0 (0)           |
| Fatigue                     | 14 (26.9)       | 1 (1.9)         |
| Diarrhea                    | 5 (9.6)         | 0 (0)           |
| Decreased appetite          | 8 (15.4)        | 1 (1.9)         |
| Fever                       | 11 (21.2)       | 1 (1.9)         |

| Infusion reaction           | 0 (0)           | 0 (0)           |

Clinical outcomes in the 1st-line group and the 2nd- or later-line group

To reveal the clinical outcome in patients who received atezolizumab plus bevacizumab as 2nd- or later-line treatment, we compared patients who received atezolizumab plus bevacizumab as 1st-line treatment (1st-line group; n = 17) and those who received atezolizumab plus bevacizumab as 2nd- or later-line treatment (2nd- or later-line group; n = 21) in terms of TTP. The baseline characteristics are shown in Table 4. There were no significant differences in age, sex, etiology, or pretreatment AFP between the two
groups. There were no statistically significant differences in pretreatment ALBI score or ECOG-PS, but baseline liver function and ECOG-PS were slightly worse in 2nd- or later-line group. The proportions of patients receiving a full dose of atezolizumab plus bevacizumab in the 1st-line group and the 2nd- or later-line group were 70.6% and 57.1%, respectively (P = 0.51). Among 17 patients who received atezolizumab plus bevacizumab as 1st-line treatment, 1 patient achieved CR, 4 patients achieved PR, 8 patients had SD, and 4 patients had PD according to the RECIST. The ORR was 29.4% and the DCR was 76.5% according to the RECIST. According to the modified RECIST, 1 patient achieved CR, 5 achieved PR, 7 had SD, and 4 had PD. The ORR was 35.3% and the DCR was 76.5% using the modified RECIST. Among the 21 patients who received atezolizumab plus bevacizumab as 2nd- or later-line treatment, 2 achieved PR, 9 had SD, and 10 had PD according to the RECIST. The ORR was 9.5% and the DCR was 52.3% using the RECIST. According to the modified RECIST, 4 patients achieved PR, 8 had SD, and 9 had PD. The ORR was 19.0% and the DCR was 57.1% using the modified RECIST. The median TTP was significantly longer in the 1st-line group than in the 2nd- or later-line group (not reached vs. 2.6 months, P = 0.02) (Fig. 5).

We next analyzed the factors associated with TTP in patients receiving atezolizumab plus bevacizumab (n = 38). In the univariate analysis, receiving atezolizumab plus bevacizumab as 2nd- or later-line therapy was the only significant factor (hazard ratio 3.82, 95% confidence interval 1.11–13.17, P = 0.03) (Table 5).
Table 4
Baseline characteristics in the 1st-line group and the 2nd- or later-line group

|                                | 1st-line group (n = 17) | 2nd- or later-line group (n = 21) | P   |

The association between the AFP response and therapeutic efficacy in patients receiving atezolizumab plus bevacizumab therapy

We investigated the AFP response as a predictor of DCR according to RECIST in patients receiving atezolizumab plus bevacizumab therapy. The AFP response was defined as a reduction in AFP from the baseline of ≥ 20%. Thirty-two patients continued atezolizumab plus bevacizumab therapy for more than 6 weeks and were included in the analysis. At 3 weeks, 12 patients showed an AFP response. The AFP response at 3 weeks had a positive predictive value (PPV) of 91.7% and a negative predictive value (NPV) of 40.0%. At 6 weeks, 12 patients showed an AFP response. The AFP response at 6 weeks had a PPV of 91.7% and an NPV of 40.0%. The TTPs of patients with and without an AFP response at 3 weeks and 6 weeks are presented in Fig. 6. There were no significant differences in the median TTP between patients with and without an AFP response at 3 weeks (3.8 months vs. 4.8 months, P = 0.09). By contrast, there was a significant difference in the median TTP between patients with and without an AFP response at 6 weeks (2.6 months vs. 4.7 months, P = 0.02). The results were similar when patients with a baseline AFP < 20 ng/mL were excluded. Although there were no significant differences in the median TTP between
patients with and without an AFP response at 3 weeks (3.8 months vs. 4.1 months, \( P = 0.08 \)), there was a significant difference in the median TTP between patients with and without an AFP response at 6 weeks (2.5 months vs. 4.7 months, \( P = 0.001 \)) (Fig. 7).

We also analyzed the association between the AFP response at 6 weeks and therapeutic efficacy stratified by patients with baseline AFPs < 20 ng/mL, 20–400 ng/mL, and > 400 ng/mL (Table 6). Among 10 patients with a baseline AFP < 20 ng/mL, 3 had an AFP response at 6 weeks. According to the RECIST, 2 patients achieved PR and 1 had SD. Among 10 patients with a baseline AFP 20–400 ng/mL, 4 had an AFP response at 6 weeks. One patient achieved PR, 2 had SD, and 1 had PD. Among 12 patients with a baseline AFP > 400 ng/mL, 5 had an AFP response at 6 weeks. One patient achieved CR, 1 achieved PR, and 3 patients had SD. There were no significant differences in the median TTP among patients with baseline AFPs < 20 ng/mL, 20–400 ng/mL, and > 400 ng/mL (5.2 months, 4.0 months, and 4.8 months, respectively; \( P = 0.19 \)) in patients with an AFP response at 6 weeks (Fig. 8).

| Baseline AFP     | Positive predictive value (PPV) | Negative predictive value (NPV) |
|------------------|---------------------------------|---------------------------------|
| < 20 ng/mL (n = 10) | 100%                            | 28.6%                           |
| 20–400 ng/mL (n = 10) | 75%                             | 50%                             |
| > 400 ng/mL (n = 12) | 100%                            | 42.9%                           |

Abbreviation: AFP, alpha-fetoprotein.

Discussion

Atezolizumab plus bevacizumab is recommended as a 1st-line therapy for advanced HCC in many guidelines, including the ASCO [18] and ESMO guidelines [19]. Some recent studies have reported the efficacy and safety of atezolizumab plus bevacizumab in Japanese patients with u-HCC in real-world practice [20–22]. To the best of our knowledge, this is the first report to reveal the difference in clinical outcome between patients receiving atezolizumab plus bevacizumab as 1st-line and 2nd- or later-line therapies and the association between the timing of the AFP response and therapeutic efficacy.

We included patients who received atezolizumab plus bevacizumab as 2nd- or later-line therapy in this study. The IMbrave150 trial [23] included only patients who had not previously received systemic therapy, and the ORR and DCR were 27.3% and 73.6%, respectively, according to the RECIST. Kuzuya et al. [20] reported an ORR of 12.5% and a DCR of 75.0% according to the RECIST in patients treated with atezolizumab plus bevacizumab after lenvatinib failure. Hiraoka et al. [21] reported that the ORRs and DCRs were 12.2% and 82.9%, respectively, in patients who received atezolizumab plus bevacizumab as 1st-line therapy, and 9.7% and 77.8%, respectively, in patients who received atezolizumab plus bevacizumab as 2nd- or later-line therapy, according to the RECIST. Iwamoto et al. [22] reported that the ORRs and DCRs were 36.8% and 94.5% in molecular targeted agent (MTA)-naïve patients, respectively,
and 34.3% and 71.9% in patients treated with MTAs, respectively, using the modified RECIST. These reports showed that there were no significant differences in the clinical response to atezolizumab plus bevacizumab in patients with and without a past history of systemic treatment. In our study, the median TTP was significantly shorter in the 2nd- or later-line group than in the first-line group. In patients previously treated with other agents, dose modification and interruption of bevacizumab were more frequent than in patients receiving atezolizumab plus bevacizumab as 1st-line therapy. The slight difference in baseline ALBI scores between two groups may also have an impact on TTP. However, there were no significant differences in the rate of AEs between the two groups.

Previous reports reported deterioration in liver function during the early period among patients treated with sorafenib [24] and lenvatinib [25]. Sangro et al. [26] reported that patients receiving nivolumab were more likely to have preserved liver function than patients receiving sorafenib. Kudo et al. [27] reported that ramucirumab did not worsen the ALBI score during the early treatment period. Changes in liver function during atezolizumab plus bevacizumab therapy were not examined in the IMbrave150 trial. Kuzuya et al. [20] reported that the ALBI score of patients receiving atezolizumab plus bevacizumab at 2 weeks was worse than that at baseline but improved at 3 and 6 weeks without any special treatment. Hiraoka et al. [21] also reported that the ALBI score was significantly worsened at 3 weeks after the introduction of atezolizumab plus bevacizumab but recovered at 6 weeks. In our study, the ALBI score at 3 weeks transiently worsened compared to baseline in patients receiving atezolizumab plus bevacizumab as 1st-line treatment but improved at 6 weeks and 9 weeks. The temporary worsening of liver function may be related to the therapeutic response, which leads to appetite loss and fatigue during the early treatment period. All patients (n = 11) with deterioration of the ALBI score at 3 weeks in the 1st-line group had PR or SD. Liver function and these AEs improved spontaneously at 6 and 9 weeks. Atezolizumab plus bevacizumab therapy can be maintained while preserving liver function in many patients.

In this study, we focused on the AFP response at 3 and 6 weeks after the administration of the combination therapy. There were no significant differences in the median TTP between patients with and without an AFP response at 3 weeks. By contrast, there was a significant difference in the median TTP between patients with and without an AFP response at 6 weeks. Kuzuya et al. reported that an early AFP response is useful to predict response to sorafenib [28] and lenvatinib [29]. Kodama et al. [30] reported that patients with sustained AFP reduction at 4 weeks after lenvatinib administration demonstrated a higher objective response. Lee et al. [31] reported that an AFP reduction > 10% within 4 weeks is an independent predictor of the best objective response to immune checkpoint inhibitor therapy. However, in patients receiving atezolizumab plus bevacizumab therapy, the antitumor response is delayed in some patients, and early treatment decisions based on the AFP response should be avoided.

In Japan, five regimens (sorafenib, regorafenib, lenvatinib, ramucirumab if AFP ≥ 400 ng/mL, and cabozantinib) can be administered after atezolizumab plus bevacizumab therapy based on the national health insurance guidelines. Because of the small cohort and short observation period, we could not examine the established clinical outcomes of post-combination therapies in real-world practice. Among the patients who received lenvatinib after combination therapy, the ORR and DCR were 50% and 75%,
respectively. Aoki et al. [32] revealed that lenvatinib demonstrated considerable antitumor effects with acceptable safety in patients with progressive and u-HCC when administered immediately after PD-1/PD-L1 blockade failure (ORR 55.6%, DCR 86.1%). Further multicenter studies on treatment after atezolizumab plus bevacizumab therapy are necessary to develop an effective treatment strategy for patients with u-HCC.

There are certain limitations to our study. The study was a retrospective single-center study with a small number of patients and a short observation period, and tumor response was not evaluated in all patients.

To our knowledge, our report is the first to reveal the difference in clinical outcome between 1st-line and 2nd- or later-line atezolizumab plus bevacizumab therapy and the association between the timing of the AFP response and therapeutic efficacy. Our data can provide useful information to develop useful therapeutic strategies for patients with u-HCC and effectively administer combination therapy.

**Conclusion**

Atezolizumab plus bevacizumab therapy was found to have similar radiological responses to the phase III IMbrave150 trial regimen in u-HCC patients when administered as 1st-line therapy. Patients receiving atezolizumab plus bevacizumab therapy as 1st-line therapy tended to have longer TTP than those receiving atezolizumab plus bevacizumab as 2nd- or later-line therapy. The AFP response at 6 weeks could be a predictive indicator of disease progression.
