The spin Hall (SH) effect is a phenomenon in which the spin current flows perpendicular to an applied electric field and causes the spin accumulation at the boundaries. However, in the presence of spin-orbit couplings, the spin current is not well defined. Here, we calculate the spin response to an electric-field gradient, which naturally appears at the boundaries. We derive a generic formula using the Bloch wave functions and the phenomenological relaxation time. We also calculate the response for the uniform Rashba model with \( \delta \)-function nonmagnetic disorder within the first-order Born approximation and corresponding vertex corrections. We find the nonzero spin accumulation, although the SH conductivity exactly vanishes.

Introduction. Spintronics is an active research field in condensed-matter physics to make use of the spin degree of freedom of electrons. Key steps are creation, transportation, and detection of spins, and, hence, the spin current has been believed to play an important role. Such a current can be generated via spin-orbit (SO) couplings perpendicular to an applied electric field. This phenomenon, proposed by D’yakonov and Perel’ \cite{1} and later by Hirsch \cite{2}, is called the spin Hall (SH) effect \cite{3}. It has attracted renewed interest since the theoretical proposals \cite{4, 5} and experimental observations in semiconductors \cite{6, 7}.

Experimentally, the spin current in the SH effect has not been directly observed. Only indirectly observed are the charge current in the inverse SH effect \cite{8, 9} and the magnetization dynamics in the ferromagnetic resonance \cite{10, 11}. In Refs. \cite{6, 7}, the spin accumulation at the boundaries was detected optically and attributed to the SH effect: The spin current is generated via the SH effect and then turns into spin at the boundaries, as depicted in Fig. 1(a). Hence, spin, rather than the spin current, is the primary physical object in order to describe these experimental results. This idea was pointed out already in the first theoretical proposal \cite{1} and repeatedly in many subsequent papers \cite{12–22}.

In the presence of SO couplings, spin is not conserved, and the spin current is not well defined. When a spin current density \( J_{sa}^{i}(t, \mathbf{x}) \) is given, there exists the corresponding spin torque density \( \tau_{a}(t, \mathbf{x}) \), and the spin continuity equation is expressed as \( \partial_{t}s_{a}(t, \mathbf{x}) + \partial_{x^{i}}J_{sa}^{i}(t, \mathbf{x}) = \tau_{a}(t, \mathbf{x}) \). Widely used is the conventional definition, \( \tilde{J}_{sa}^{i}(k) = \{ \tilde{s}_{a}, \tilde{v}^{i}(k) \}/2 \), where \( \tilde{s}_{a} \) and \( \tilde{v}^{i}(k) \) are the spin and velocity operators, respectively. However, this definition is unphysical in the sense that its uniform equilibrium expectation value is nonzero in noncentrosymmetric systems, such as the Rashba and Dresselhaus models \cite{23}. Another definition is the so-called conserved spin current \cite{24, 25}. If the spin torque vanishes in average over the whole system, we can define the spin torque dipole density as \( \tau_{a}(t, \mathbf{x}) = -\partial_{x^{i}}P_{ra}^{i}(t, \mathbf{x}) \), and \( \tilde{J}_{sa}^{i}(t, \mathbf{x}) = J_{sa}^{i}(t, \mathbf{x}) + P_{ra}^{i}(t, \mathbf{x}) \) is conserved on average. This definition has interesting properties, such as the Středa formula between the SH conductivity and the SO magnetic susceptibility \cite{26} and the Mott relation between the SH and the spin Nernst conductivities \cite{27, 28}. Whatever definition we choose, however, we need to consider the corresponding spin torque density to evaluate the observable spin density. Note that using the scattering approach for mesoscopic systems, the prohibition of the equilibrium spin current \cite{29}, an electrical measurement scheme \cite{30}, and the Onsager reciprocal relations \cite{31} were shown without defining the spin current.

In the case of the Rashba model that describes \( n \)-type semiconductor heterostructures, the SH conductivity of the conventional spin current exactly vanishes when the vertex corrections are taken into account \cite{12, 32–37}. This cancellation is owing to the special property that the conventional spin current operator is proportional to the time derivative of the spin operator \cite{34–36}. The SH conductivity of the conserved spin current also vanishes \cite{38}. Following the typical scenario in Fig. 1(a), the spin accumulation would be zero but, in fact, observed experimentally \cite{7}. Thus, it is clearly insufficient to focus on the SH conductivity only.

In contrast to the spin current, spin is well defined. Regarding the Rashba model, the spin polarization at the boundaries has been calculated using the coupled diffusion equations obtained microscopically \cite{12, 13, 17, 18}, the Landauer-Keldysh formalism \cite{14–16}, and the scattering problem \cite{19–21}. Now it is well understood that the essence of the SH effect is the spin accumulation. However, in these formalisms, we need to impose the open boundary conditions or attach the leads to the system. It is difficult to deal with such finite geometries in first-principles calculations for real materials, which may have multiple bands and complicated SO couplings.

Hence, the Kubo formula of the SH conductivity is widely used in first-principles calculations \cite{39–41} despite the aforementioned problems. It is highly desired to establish the Kubo formula of the spin accumulation.
Recently, one of the authors considered the spin response to an electric-field gradient [42]. When a uniform electric field is applied to a finite-size system, the charge current vanishes at the boundaries. What we call the electric field here effectively describes such a boundary effect, and its gradient has peaks there as depicted in Fig. 1(b). Since the spin-diffusion length that characterizes the spin accumulation is much longer than the mean free path, we can safely assume that the electric field slowly decreases towards the boundaries. Then, the spin accumulation can be emulated imposing the periodic boundary conditions, which are compatible to first-principles calculations. The theory also explains generation of spin current using the SH effect or the spin pumping and detection using the inverse SH effect in terms of the nonlocal spin fluctuation.

In this Letter, we study the spin response to the electric-field gradient with the quantum-mechanical linear-response theory. First, we derive a generic formula expressed by the Bloch wave functions. Although disorder effects are taken into account via a phenomenological relaxation time, the formula can be applied to any Bloch Hamiltonian. Second, we calculate the spin response with the Green’s functions. We consider the uniform Rashba model with δ-function nonmagnetic disorder within the first Born approximation and corresponding vertex corrections, which results in the vanishing SH conductivity [12, 32–37]. Nonetheless, we find the nonzero spin accumulation, which is consistent with the experimental result [7]. This theory enables us to calculate the observable quantity in the SH effect for real materials.

**Bloch formulas.** First, we calculate the spin–charge-current correlation function that characterizes \( \langle \hat{\delta}_a \rangle (\Omega, Q) = \chi_{\hat{\delta}_a, j_i}^R (\Omega, Q) A_j (\Omega, Q) \), where \( \Omega \) and \( Q \) are the frequency and the wave number of an external vector potential. Using the Bloch wave-functions \( u_n (k) \) for the Bloch Hamiltonian \( \tilde{H}(k) \), the correlation function is expressed as

\[
\chi_{\hat{\delta}_a, j_i}^R (\Omega, Q) = - \frac{q}{\hbar} \sum_{nm} \int \frac{d^d k}{(2\pi)^d} \langle u_n (k_-) | \hat{\delta}_a | u_m (k_+) \rangle \times \langle u_m (k_+) | \hat{\delta}_i (k; Q) | u_n (k_-) \rangle \\
\times \{ f(\epsilon_n (k_-)) - f(\epsilon_m (k_+)) \} \\
\times \hbar \Omega + \epsilon_m (k_+) - \epsilon_n (k_-) + i\eta \\
= \chi_{\hat{\delta}_a, j_i}^R (0, Q) + (i\Omega) a_{\hat{\delta}_a, j_i}^R (\Omega, Q),
\]

where \( q \) is the electron charge, \( d \) is the spatial dimension, \( \eta \rightarrow 0 \) is the convergence factor, \( \hat{\delta}_i (k; Q) = [\hat{\delta}_i (k_+) + \hat{\delta}_i (k_-)]/2 \) with \( k_\perp = k \pm Q/2 \), and \( f(\epsilon) = [e^{(\epsilon - \mu)/T} + 1]^{-1} \) is the Fermi distribution function. We expand Eq. (1) up to the first order with respect to \( Q \) with keeping \( \Omega \) nonzero. The first term in Eq. (1) takes the form of \( \chi_{\hat{\delta}_a, j_i}^R (0, Q) = e^{ijk} (iQ) \chi_{\hat{\delta}_a}^R \), and we reproduce the SO magnetic susceptibility [43, 44],

\[
\chi_{\hat{\delta}_a}^R = - \frac{q}{\hbar} \sum_n \int \frac{d^d k}{(2\pi)^d} \left\{ -\epsilon_{ijk} s_{na} \hat{\partial}_{k_j} \epsilon_n + s_{na} m_{nk} \right\} f'(\epsilon_n) \\
+ b_{nak} f(\epsilon_n).
\]

The argument of \( k \) is omitted for simplicity. We have introduced \( s_{na} = \langle u_n | \hat{\delta}_a | u_n \rangle \), the magnetic moment \( m_{nk} [45–47] \), spin magnetic quadrupole moment \( s_{na} [48, 49] \), and spin Berry curvature \( b_{nak} \) as

\[
e^{ijk} m_{nak} = \text{Im} \left[ \langle \partial_{k_i} u_n | (\epsilon_n - \tilde{H}) | \partial_{k_j} u_n \rangle \right],
\]

\[
s_{nak} = \text{Im} \left( \langle \hat{\delta}_{k_i} u_n | Q_n \hat{\delta}_{a} | u_n \rangle \right),
\]

\[
e^{ijk} b_{nak} = - \text{Im} \left( \langle \partial_{k_i} u_n | Q_n (s_{na} + \hat{\delta}_a) \hat{Q}_n | \partial_{k_j} u_n \rangle + \sum_{m \neq n} \right) \\
\times \frac{\text{Im} \left( \langle u_n | \hat{\delta}_a | u_m \rangle \langle u_m | \partial_{k_i} \epsilon_n + \hbar \epsilon_n \hat{Q}_n | \partial_{k_j} u_n \rangle \right)}{\epsilon_n - \epsilon_m} \\
- (i \leftrightarrow j),
\]

with \( \hat{Q}_n = 1 - | u_n \rangle \langle u_n | \) being the antiprojection operator. Equation (3c) is a spin analog of the Berry curvature because it is reduced to the Berry curvature when \( \hat{\delta}_a \) is replaced by 1 and totally antisymmetric with respect to \( \partial_{k_i}, \hat{Q}_n, \) and \( \partial_{k_j} \). Here, \( B^a \) is the Zeeman field conjugate to \( \hat{\delta}_a \).

The second term in Eq. (1) takes the form of [44]

\[
e^{ijk} \chi_{\hat{\delta}_a, j_i}^R (0, Q) = [\chi_{\hat{\delta}_a, j_i}^R (\Omega, Q) - \chi_{\hat{\delta}_a, j_i}^R (0, Q)]/(i\Omega)
\]
by electromagnetic fields as reversal symmetry. Note that we drop Eqs. (5b) and (5c) describe the spin accumulation in-
Equation (5a) describes the Edelstein effect [50], whereas our main results,

\[ \langle \Delta \hat{s}_a \rangle (\Omega, Q) = \frac{\hbar}{\hbar \Omega + i \eta} \alpha_{a}^j E_j (\Omega, Q) \]

where \[ \alpha_{a}^j = - \frac{q}{\hbar} \sum_n \int \frac{d^2 k}{(2\pi)^2} s_{na} \partial k_i \epsilon_n f'(\epsilon_n), \] (5a)

\[ \gamma_{a}^{ij(I)} = - \frac{q}{\hbar^2} \sum_n \int \frac{d^2 k}{(2\pi)^2} s_{na} \partial k_i \epsilon_n \partial k_j \epsilon_n f'(\epsilon_n), \]

\[ \gamma_{a}^{ij(II)} = \frac{q}{\hbar} \sum_n \int \frac{d^2 k}{(2\pi)^2} \left( s_{na}^{ij} \partial k_i \epsilon_n - s_{na} \epsilon^{ijk} m_{nk} \right) f'(\epsilon_n). \] (5c)

Equation (5a) describes the Edelstein effect [50], whereas Eqs. (5b) and (5c) describe the spin accumulation induced by the electric-field gradient. Note that we drop the interband Fermi-sea term because it breaks the time-reversal symmetry.

Combining Eqs. (2) and (4), the spin density is induced by electromagnetic fields as

\[ \langle \Delta \hat{s}_a \rangle (\Omega, Q) = \frac{\hbar}{\hbar \Omega + i \eta} \alpha_{a}^j E_j (\Omega, Q) \]

\[ + \left[ \frac{\hbar^2}{(\hbar \Omega + i \eta)^2} \gamma_{a}^{ij(I)} - \frac{\hbar}{\hbar \Omega + i \eta} \gamma_{a}^{ij(II)} \right] \]

\[ \times (iQ_i) E_j (\Omega, Q) + \epsilon_{a}^{q, B} B^k (\Omega, Q). \] (6)

Taking the limit of \( \Omega \to 0 \) and introducing the phenomenological relaxation time \( \hbar/\eta \), we arrive at one of our main results,

\[ \langle \Delta \hat{s}_a \rangle (0, Q) = \frac{\hbar}{\eta} \alpha_{a}^j E_j (0, Q) - \left[ \frac{\hbar^2}{\eta^2} \gamma_{a}^{ij(I)} + \frac{\hbar}{\eta} \gamma_{a}^{ij(II)} \right] \]

\[ \times (iQ_i) E_j (0, Q). \] (7)

Let us apply the above formulas to the uniform Rashba model,

\[ \hat{H}(k) = \frac{\hbar^2 k^2}{2m} + \alpha(k_y \sigma_x - k_x \sigma_y), \] (8)

where \( \sigma \) is the Pauli matrix corresponding to the spin operator \( \hat{s} = (\hbar/2) \sigma \). The eigenvalues are \( \epsilon_{\sigma}(k) = \hbar^2 k^2/2m + \sigma \hbar \alpha k \). At \( T = 0 \), we obtain the SO magnetic susceptibility (2) and spin accumulation (5c) as [44]

\[ \chi_{zz}^{so} = - \frac{q}{4\pi} \begin{cases} \frac{1}{\sqrt{1 + 2\mu/ma^2}} & (\mu > 0) \\ \frac{1}{\sqrt{1 + 2\mu/ma^2}} & (\mu < 0) \end{cases}, \] (9a)

Now we evaluate the spin response to a vector potential,

\[ \langle \Delta \hat{s}_z \rangle (\Omega, Q) = q A_y (\Omega, Q) \int \frac{d\epsilon}{2\pi} \int \frac{d^2 k}{(2\pi)^2} \text{tr} \left[ \hat{s}_z \hat{G}(\epsilon +, \epsilon -) \hat{v}_y (k; Q) \hat{G}(\epsilon -, k -) \right]. \]
\[-i q A_y (\Omega, Q) \int \frac{d\epsilon}{2\pi} \int \frac{d^2 k'}{(2\pi)^2} \text{tr} \left\{ -\hat{s}_z \hat{G}^{R}(\epsilon_+, k_+) \hat{v}^y(k; Q) \hat{G}^{A}(\epsilon_-, k_-) [f(\epsilon_+) - f(\epsilon_-)] + \hat{s}_z \hat{G}^{A}(\epsilon_+, k_+) \hat{v}^y(k; Q) \hat{G}^{A}(\epsilon_-, k_-) f(\epsilon_+) - \hat{s}_z \hat{G}^{R}(\epsilon_+, k_+) \hat{v}^y(k; Q) \hat{G}^{R}(\epsilon_-, k_-) f(\epsilon_-) \right\}, (13)\]

in which \(\epsilon_{\pm} = \epsilon \pm i\hbar \Omega/2\), up to the first order with respect to \(\Omega\) and \(Q_x\). The zeroth-order terms with respect to \(Q_x\) vanish owing to the \(C_4\) symmetry of the Rashba model. The first-order terms are decomposed into two; one is the zeroth-order Fermi-surface term and describes the spin accumulation. These terms are expressed as [44]

\[
\langle \Delta \hat{s}_z \rangle^{(0,1,1)}(\Omega, Q) = \frac{i \hbar q}{2} Q_x A_y (\Omega, Q) \int \frac{d\epsilon}{2\pi} f'(\epsilon) \int \frac{d^2 k'}{(2\pi)^2} \text{tr} \left\{ \hat{s}_z \hat{G}^{A}(\epsilon_+, k_+) \hat{v}^y(k; Q) \hat{G}^{A}(\epsilon_-, k_-) f(\epsilon_+) - \hat{s}_z \hat{G}^{R}(\epsilon_+, k_+) \hat{v}^y(k; Q) \hat{G}^{R}(\epsilon_-, k_-) f(\epsilon_-) \right\}, (14a)\]

and diagrammatically represented in Fig. 2(a). The arguments of \(\epsilon\) and \(k\) are omitted for simplicity. In the Fermi-surface term (14b) that involves both the retarded and the advanced Green’s functions, we have replaced \(\hat{v}^y(k)\) and \(\hat{s}_z\) with \(\hat{V}^y(\epsilon, k)\) and \(\hat{S}_z(\epsilon)\), respectively. These renormalized vertices, diagrammatically represented in Figs. 2(b) and 2(c), are obtained by solving

\[
\hat{V}^y(\epsilon, k) = \hat{v}^y(k) + n_i v_i^2 \int \frac{d^2 k'}{(2\pi)^2} \hat{G}^{R}(\epsilon, k') \hat{V}^y(\epsilon, k') \hat{G}^{A}(\epsilon, k'), (15a)\]

\[
\hat{S}_z(\epsilon) = \hat{s}_z + n_i v_i^2 \int \frac{d^2 k'}{(2\pi)^2} \hat{G}^{A}(\epsilon, k') \hat{S}_z(\epsilon) \hat{G}^{R}(\epsilon, k'). (15b)\]

For the bare velocity vertex \(\hat{v}^y(k) = \hbar k_y/m + \sigma_x\) and spin vertex \(\hat{s}_z = (\hbar/2)\sigma_z\), the renormalized vertices are \(\hat{V}^y(\epsilon, k) = \hbar k_y/m + \alpha V^{yx}(\epsilon)\sigma_x\) and \(\hat{S}_z(\epsilon) = (\hbar/2)S_z^x(\epsilon)\sigma_z\), respectively.

In the limit of \(\Gamma_0 \to +0\), Eq. (14a) reproduces the SO magnetic susceptibility (9a) obtained by the Bloch formula. To neglect the vertex corrections, we only have to put \(\hat{V}^{yx}(\epsilon) = \hat{S}_z^x(\epsilon) = 1\), and Eq. (14b) reproduces Eq. (9b) by identifying \(\eta \mapsto 2\Gamma(\epsilon)\). When we take into account the vertex corrections, we reproduce [32, 44]

\[
V^{yx}(\epsilon) = \begin{cases} 0 & (\epsilon > 0) \\ -2\epsilon/m\alpha^2 & (\epsilon < 0) \end{cases}, (16)\]

and \(S_z^x(\epsilon) = 1\) [50]. Then, the correct spin accumulation at \(T = 0\) becomes [44]

\[
\langle \Delta \hat{s}_z \rangle^{(1,1,1)}(\Omega, Q) = -\frac{\hbar}{2\Gamma(\mu)} \times \left( -\frac{q}{8\pi} \right) (iQ_x) E_y(\Omega, Q)\]

This equation is another main result. The spin accumulation is nonzero even in the case where the chemical potential is below the Rashba crossing. We emphasize again that the SH conductivity vanishes in our setup [12, 32–37]. If we consider the diffusion process, the spin accumulation decays in the scale of the spin-diffusion length [42] as in the experimental [7] and theoretical results [13–17].

**Discussion.** First, let us discuss the directions of the spin and electric field. The second term of the Bloch formula (5c) involves the spin \(s_{na}\) and the orbital magnetic moment \(m_{nk}\). Since these two are parallel to each other, the spin accumulation takes the form of \(\langle \Delta \hat{s}_n \rangle(0, Q) \propto \left[ i [Q \times E(0, Q)]_a \right]\), more precisely, \(\langle \Delta \hat{s}_n \rangle(0, Q) \propto \left[ i [Q \times (\Delta \hat{J})(0, Q)]_a \right]\), considering the boundary effect as argued in the Introduction. Thus, the direction of the spin accumulation is consistent with the typical scenario of the SH effect.

Second, we discuss a relation between our results and the previous results on the SH conductivity. By multiplying \(-i\Omega\) to Eq. (6), we obtain the time derivative of the spin expectation value. If we take the limits of \(\Omega \to 0\) and \(\eta \to +0\) in the arbitrary order, we may obtain

\[
(-i\Omega)\langle \Delta \hat{s}_n \rangle(\Omega, Q) = \alpha_a E_j(\Omega, Q) - \frac{\hbar}{\eta} \gamma_{ij}^{(I)} + (\gamma_{ij}^{(II)} + \epsilon_{ij}^{(III)} \chi_{nk}^{SO}) \times (iQ_a) E_j(\Omega, Q). (18)\]

Here, we have used Faraday’s law, \((-i\Omega) B(\Omega, Q) = -(iQ) \times E(\Omega, Q)\). Since the second term is the diver-
gence, we can read the spin (Hall) conductivity as
\[ \sigma_{sa}^{ij} = \frac{\hbar}{\gamma_a} \gamma_{ai}^{(I)} + \gamma_{ai}^{(II)} + \epsilon^{ijk} \chi_{ak}^{so}, \]
where \( \gamma_{ai}^{(I)} \) and \( \gamma_{ai}^{(II)} \) are the renormalized velocity vertex and the renormalized spin vertex, respectively.

The filled squares, open squares, and open circles represent the bare vertices of \( \hat{v}^x \), \( \hat{v}^y \), and \( \hat{s}_z \), respectively.

We have also calculated the response for the uniform Rashba model with \( \delta \)-function nonmagnetic disorder using the first-order Born approximation and corresponding ladder-type vertex corrections. Although the SH conductivity vanishes \( [12, 32–37] \), the spin response \( (17) \) is nonzero as observed experimentally \( [7] \). This theory enables us to calculate the spin accumulation in the SH effect without imposing the open boundary conditions or attaching the leads and, hence, can be implemented in first-principles calculations for real materials.

**Acknowledgments.** A.S. thanks J. Fujimoto for fruitful discussions on the diagram technique. We also thank E. I. Rashba for informing us of Refs. \([17, 51]\).
