ABSTRACT

A general-relativistic theory of cosmology, the dynamical variables of which are those of Hubble’s, namely distances and redshifts, is presented. The theory describes the universe as having a three-phase evolution with a decelerating expansion followed by a constant and an accelerating expansion, and it predicts that the universe is now in the latter phase. The theory is actually a generalization of Hubble’s law taking gravity into account by means of Einstein’s theory of general relativity. The equations obtained for the universe expansion are elegant and very simple. It is shown, assuming $\Omega_0 = 0.24$, that the time at which the universe goes over from a decelerating to an accelerating expansion, i.e. the constant expansion phase, occurs at $0.03\tau$ from the big bang, where $\tau$ is the Hubble time in vacuum. Also, at that time the cosmic radiation temperature was 11K. Recent observations of distant supernovae imply, in defiance of expectations, that the universe growth is accelerating, contrary to what has always been assumed that the expansion is slowing down due to gravity. Our theory confirms these recent experimental results by showing that the universe now is definitely in a stage of accelerating expansion.
I. INTRODUCTION

In this paper we present a theory of cosmology that is based on Einstein’s general relativity theory. The theory is formulated in terms of directly measured quantities, i.e. distances, redshifts and the matter density of the universe.

The general-relativistic theory of cosmology started in 1922 with the remarkable work of A. Friedmann [1,2], who solved the Einstein gravitational field equations and found that they admit non-static cosmological solutions presenting an expanding universe. Einstein, believing that the universe should be static and unchanged forever, suggested a modification to his gravitational field equations by adding to them the so-called cosmological term which can stop the expansion.

Soon after that E. Hubble [3,4] found experimentally that the far-away galaxies are receding from us, and that the farther the galaxy the bigger its velocity. In simple words, the universe is indeed expanding according to a simple physical law that gives the relationship between the receding velocity and the distance,

\[ v = H_0 R. \]  

Equation (1.1) is usually referred to as the Hubble law, and \( H_0 \) is called the Hubble constant. It is tacitly assumed that the velocity is proportional to the actual measurement of the redshift \( z \) of the receding objects by using the non-relativistic relation \( z = v/c \), where \( c \) is the speed of light in vacuum.

The Hubble law does not resemble standard dynamical physical laws that are familiar in physics. Rather, it is a cosmological equation of state of the kind one has in thermodynamics that relates the pressure, volume and temperature, \( pV = RT \) [5]. It is this Hubble’s equation of state that will be extended so as to include gravity by use of the full Einstein theory of general relativity. The obtained results will be very simple, expressing distances in terms of redshifts; depending on the value of \( \Omega = \rho/\rho_c \) we will have accelerating, constant and decelerating expansions, corresponding to \( \Omega < 1 \), \( \Omega = 1 \) and \( \Omega > 1 \), respectively. But the
last two cases will be shown to be excluded on physical evidence, although the universe had
decelerating and constant expansions before it reached its present accelerating expansion
stage. As is well known the standard FRW cosmological theory does not deal directly with
Hubble’s measured quantities, the distances and redshifts. Accordingly, the present theory
can be compared directly with important recent observations made by astronomers which
defy expectations.

In Sections 2 and 3 we review the standard Friedmann and Lemaître models. In Section
4 we mention some points in those theories. In Section 5 we present our cosmological theory
written in terms of distances and redshifts, whereas Section 6 is devoted to the concluding
remarks.

II. REVIEW OF THE FRIEDMANN MODELS

Before presenting our theory, and in order to fix the notation, we very briefly review the
existing theory [6,7]. In the four-dimensional curved space-time describing the universe, our
spatial three-dimensional space is assumed to be isotropic and homogeneous. Co-moving
coordinates, in which \( g_{00} = 1 \) and \( g_{0k} = 0 \), are employed [8,9]. Here, and throughout our
paper, low-case Latin indices take the values 1, 2, 3 whereas Greek indices will take the
values 0, 1, 2, 3, and the signature will be \((+−−−)\). The four-dimensional space-time is
split into \( 1 \oplus 3 \) parts, and the line-element is subsequently written as

\[
\begin{align*}
ds^2 &= dt^2 - dl^2, \\
&= (3)g_{kl}dx^kdx^l = -g_{kl}dx^kdx^l, \\
\end{align*}
\]

(2.1)

and the \( 3 \times 3 \) tensor \((3)g_{kl} \equiv -g_{kl}\) describes the geometry of the three-dimensional space at
a given instant of time. In the above equations the speed of light \( c \) was taken as unity.

Because of the isotropy and homogeneity of the three-geometry, it follows that the cur-
vature tensor must have the form

\[
(3)R_{mnls} = K \left[ (3)g_{ms}(3)g_{nk} - (3)g_{mk}(3)g_{ns} \right],
\]

(2.2)
where $K$ is a constant, the curvature of the three-dimensional space, which is related to the Ricci scalar by $R = -6K$ [10]. By simple geometrical arguments one then finds that

$$dl^2 = \left(1 - r^2/R^2\right)^{-1} dr^2 + r^2 \left(d\theta^2 + \sin^2 \theta d\phi^2\right), \quad (2.3)$$

where $r < R$. Furthermore, the curvature tensor corresponding to the metric (2.3) satisfies Eq. (2.2) with $K = 1/R^2$. In the “spherical” coordinates $(t, r, \theta, \phi)$ we thus have

$$g_{11} = - \left(1 - r^2/R^2\right)^{-1}. \quad (2.4)$$

$R$ is called the radius of the curvature (or the expansion parameter) and its value is determined by the Einstein field equations.

One then has three cases: (1) a universe with positive curvature for which $K = 1/R^2$; (2) a universe with negative curvature, $K = -1/R^2$; and (3) a universe with zero curvature, $K = 0$. The $g_{11}$ component for the negative-curvature universe is given by

$$g_{11} = - \left(1 + r^2/R^2\right)^{-1}, \quad (2.5)$$

where $r < R$. For the zero-curvature universe one lets $R \to \infty$.

In this theory one has to change variables in order to get the solutions of the Einstein field equations according to the type of the universe. Accordingly, one makes the substitution $r = R \sin \chi$ for the positive-curvature universe, and $r = R \sinh \chi$ for the negative-curvature universe. The time-like coordinate is also changed into another one $\eta$ by the transformation $dt = Rd\eta$. The corresponding line elements then become:

$$ds^2 = R^2(\eta) \left[d\eta^2 - d\chi^2 - \sin^2 \chi \left(d\theta^2 + \sin^2 \theta d\phi^2\right)\right] \quad (2.6a)$$

for the positive-curvature universe,

$$ds^2 = R^2(\eta) \left[d\eta^2 - d\chi^2 - \sinh^2 \chi \left(d\theta^2 + \sinh^2 \theta d\phi^2\right)\right] \quad (2.6b)$$

for the negative-curvature universe, and

$$ds^2 = R^2(\eta) \left[d\eta^2 - dr^2 - r^2 \left(d\theta^2 + \sin^2 \theta d\phi^2\right)\right] \quad (2.6c)$$
for the flat three-dimensional universe. In the sequel, we will see that the time-like coordinate in our theory will take one more different form.

The Einstein field equations are then employed in order to determine the expansion parameter $R(\eta)$. In fact only one field equation is needed,

\begin{equation}
R_0^0 - \frac{1}{2} \delta_0^0 R + \Lambda \delta_0^0 = 8\pi G T_0^0, \tag{2.7}
\end{equation}

where $\Lambda$ is the cosmological constant, and $c$ was taken as unity. In the Friedmann models one takes $\Lambda = 0$, and in the comoving coordinates used one easily finds that $T_0^0 = \rho$, the mass density. While this choice of the energy-momentum tensor is acceptable in standard general relativity and in Newtonian gravity, we will argue in the sequel that it is not so for cosmology. At any rate, using $\rho(t) = M/2\pi^2 R^3$, where $M$ is the “mass” and $2\pi^2 R^3$ is the “volume” of the universe, one obtains

\begin{equation}
3 \left[ (dR/dt)^2 + 1 \right] / R^2 = 4GM/\pi R^3 + \Lambda, \tag{2.8a}
\end{equation}

or, in terms of $\eta$ along with taking $\Lambda = 0$,

\begin{equation}
3 \left[ (dR/d\eta)^2 + R^2 \right] / R = 4GM/\pi. \tag{2.9a}
\end{equation}

The solution of this equation is

\begin{equation}
R = \ast R \left( 1 - \cos \eta \right), \tag{2.10a}
\end{equation}

where $\ast R = 2GM/3\pi$, and from $dt = Rd\eta$ we obtain

\begin{equation}
t = \ast R \left( \eta - \sin \eta \right). \tag{2.11a}
\end{equation}

Equations (10a) and (11a) are those of a cycloid, and give a full representation for the expansion parameter of the universe. Fig. 2.1 shows a plot of $R$ as a function of $t$. At $t = 0$, $\pm 2\pi \ast R$, $\pm 4\pi \ast R$, etc., $R(t)$ vanishes; that is, the universe contracts to a point. Since the density will become very large when this is about to happen, our approximate expression for the energy-momentum tensor will fail. We should also keep in mind that the
classical Einstein equation becomes inapplicable at very high densities. It is therefore not clear exactly what happens at the singular points of Fig. 2.1, and we do not know whether the universe actually has the periodic behavior suggested by this figure.

Similarly, one obtains for the negative-curvature universe the analog to Eqs. (2.8a) and (2.9a),

\[ 3 \left[ \left( \frac{dR}{dt} \right)^2 - 1 \right] / R^2 = 4GM/\pi R^3 + \Lambda, \tag{2.8b} \]
\[ 3 \left[ \left( \frac{dR}{d\eta} \right)^2 - R^2 \right] / R = 4GM/\pi, \tag{2.9b} \]

the solution of which is given by

\[ R = *R \left( \cosh \eta - \eta \right), \tag{2.10b} \]
\[ t = *R \left( \sinh \eta - \eta \right). \tag{2.11b} \]

Fig. 2.2 shows \( R \) as a function of \( t \). The universe begins with a big bang and continues to expand forever. As \( t \to \infty \), the universe gradually becomes flat. Again, the state near the singularity at \( t = 0 \) is not adequately described by our equations.

Finally, for the universe with a flat three-dimensional space the Einstein field equations yield the analog to Eqs. (2.8a) and (2.9a),

\[ 3 \left( \frac{dR}{dt} \right)^2 / R^2 = 4GM/\pi R^3 + \Lambda, \tag{2.8c} \]
\[ 3 \left( \frac{dR}{d\eta} \right)^2 / R = 4GM/\pi. \tag{2.9c} \]

As a function of \( t \), the solution is

\[ R = \left( 3GM/\pi \right)^{1/3} t^{2/3}. \tag{2.10c} \]

This function is plotted in Fig. 2.3. As \( t \to \infty \), the four-geometry tends to become flat.

\section*{III. Lemaître Models}

An extension of the Friedmann models was carried out by Lemaître, who considered universes with zero energy-momentum but with a non-zero cosmological constant. While
these models are of interest mathematically they have little, if any, relation to the physical universe because we know that there is baryonic matter. The behavior of the universe in this model will be determined by the cosmological term; this term has the same effect as a uniform mass density \( \rho_{\text{eff}} = -\Lambda/4\pi G \), which is constant in space and time. A positive value of \( \Lambda \) corresponds to a negative effective mass density (repulsion), and a negative value of \( \Lambda \) corresponds to a positive mass density (attraction). Hence, we expect that in the universe with a positive value of \( \Lambda \), the expansion will tend to accelerate; whereas in a universe with negative value of \( \Lambda \), the expansion will slow down, stop, and reverse.

The equations of motion for \( R(t) \) have been derived in Section 2, but here it will be assumed that \( \Lambda \neq 0 \) whereas the energy-momentum tensor appearing in Eq. (2.7) to be zero. For the positive-curvature universe one obtains the analog to Eq. (2.8a),

\[
3 \left[ (dR/dt)^2 + 1 \right] / R^2 = \Lambda. \tag{3.1a}
\]

From equation (3.1a) one immediately concludes that \(-1 + \Lambda R^2/3\) cannot be negative. This implies that \( \Lambda > 0 \), and that the value of \( R \) can never be less than \((3/\Lambda)^{1/2}\), i.e. the radius of curvature cannot be zero which excludes the possibility of a big bang.

The integration of Eq. (3.1a) yields,

\[
R(t) = (3/\Lambda)^{1/2} \cosh \left( (\Lambda/3)^{1/2} t \right), \tag{3.2a}
\]

where \( t \) was taken zero when \( R \) has its minimum value. Fig. 3.1, curve (a), shows a plot of \( R \) as a function of \( t \). As is seen, for \( t > 0 \) the universe expands monotonically, and as \( t \) increases, \( R \) increases too and the universe becomes flat.

Similarly, one obtains for the negative-curvature universe the analog to Eq. (3.1a),

\[
3 \left[ (dR/dt)^2 - 1 \right] / R^2 = \Lambda, \tag{3.1b}
\]

the integration of which gives,

\[
R(t) = (3/\Lambda)^{1/2} \sinh \left( (\Lambda/3)^{1/2} t \right), \tag{3.2b}
\]
for $\Lambda > 0$, and

$$R(t) = (-3/\Lambda)^{1/2} \cosh \left[ (-\Lambda/3)^{1/2} t \right]$$  \hspace{1cm} (3.2c)$$

for $\Lambda < 0$. These functions are plotted in Fig. 3.1, curves (b) and (c), respectively. It will be noted that both universes begin with a big bang at $t = 0$. The first of these curves expands monotonically, whereas the second one oscillates. In our actual universe, the mass density near the singularity at $t = 0$ was extremely large, and hence this model cannot be used to describe its behavior near this time.

Finally, for the universe with a flat three-dimensional space the Einstein field equations yield the analog to Eq. (3.1a),

$$3 \left( \frac{dR}{dt} \right)^2 / R^2 = \Lambda.$$  \hspace{1cm} (3.1c)$$

This equation has meaning only for $\Lambda > 0$, and it has the solution

$$R(t) = R(0) \exp \left[ (\Lambda/3)^{1/2} t \right].$$  \hspace{1cm} (3.2d)$$

This universe expands exponentially. This model, described by Eq. (3.2d), is usually called the de Sitter universe.

IV. REMARKS OF THE STANDARD THEORY

To conclude the discussion on the Friedmann and Lemaître universes, we briefly discuss the case in which both the matter density and the cosmological constant are not zero. It will be noted that exact solutions of the differential equations describing the expansion of the universe in that case, given by Eqs. (2.8), are not known. These general models can be thought of as a combination of the Friedmann and Lemaître models.

Consider a universe that begins with a big bang. At an early time, the universe must have been very dense, and we can neglect the cosmological term. Hence, we have approximately a Friedmann universe. As the universe expands and the mass density decreases, the cosmological term will become more important. In the Friedmann models of zero and negative
curvature, the universe expands monotonically and the decrease in mass density is mono-
tonic too. The cosmological term will ultimately dominate the behavior of the universe, and
it gradually turns into an empty Lemaître universe with zero or negative curvature. In the
case of negative curvature with $\Lambda < 0$, the expansion will stop at some later time, reverses
and finally ends up in a re-contracting universe of negative curvature.

In the case of a Friedmann universe with a positive curvature, the mass density reaches
minimum when the radius of curvature is at its maximum. Hence, the cosmological term
will dominate the behavior of the universe only if it is sufficiently large compared with
the minimum mass density. The critical value of $\Lambda$ is given by $\Lambda_E = (\pi/2GM)^2$. If $\Lambda$ is
larger than $\Lambda_E$, then the Friedmann universe with positive curvature gradually turns into
an expanding Lemaître universe with positive curvature (Fig. 4.1). In the case $\Lambda = \Lambda_E$, the
transition is never completed and the expansion stops at a constant value of $R = 1/\Lambda_E^{1/2}$.
This static universe is called the Einstein universe. The universe at this value of $R$, however,
is not stable. Any perturbation in $R$ leads either to monotonic expansion (toward an empty
Lemaître model) or to contraction (toward a contracting Friedmann universe).

In the final analysis, it follows that the expansion of the universe is determined by
the so-called cosmological parameters. These can be taken as the mass density $\rho$, the
Hubble constant $H$ and the deceleration parameter $q$. In the following we give a brief
review of these parameters and the relationship between them. In the rest of the paper
we will concentrate on the theory with dynamical variables that are actually measured by
astronomers: distances, redshifts and the mass density.

Equations (2.8) can be written as

$$3 \left( H^2 + k/R^2 \right) = 8\pi G \rho + \Lambda,$$

where $k = 1, 0, \text{or } -1$, for the cases of positive, zero, or negative curvature, respectively.
Using Eq. (4.1) and $\Omega = \rho/\rho_c$, where $\rho_c = 3H_0^2/8\pi G$, one obtains

$$\Omega = 1 + k/H^2 R^2 - \Lambda/3H^2.$$

(4.2)
It follows from these equations that the curvature of the universe is determined by $H$, $\rho$ and $\Lambda$, or equivalently, $H$, $\Omega$ and $\Lambda$:

$$\Omega > 1 - \Lambda/3H^2, \quad (4.3a)$$

for positive curvature,

$$\Omega < 1 - \Lambda/3H^2, \quad (4.3b)$$

for negative curvature, and

$$\Omega = 1 - \Lambda/3H^2, \quad (4.3c)$$

for zero curvature.

The deceleration parameter is defined as

$$q \equiv - \left[ 1 + \left( \frac{1}{H^2} \right) \frac{dH}{dt} \right], \quad (4.4)$$

and it can be shown that

$$q = \Omega/2 - \Lambda/3H^2. \quad (4.5)$$

Using Eq. (4.5) we can eliminate $\Lambda$ from Eqs. (4.3) and obtain

$$3\Omega/2 > 1 + q, \quad (4.6a)$$

for positive curvature,

$$3\Omega/2 < 1 + q, \quad (4.6b)$$

for negative curvature, and

$$3\Omega/2 = 1 + q, \quad (4.6c)$$

for zero curvature.

It is worthwhile mentioning that one of the Friedmann theory assumptions is that the type of the universe is determined by $\Omega = \rho/\rho_c$, where $\rho_c = 3H_0^2/8\pi G$, which requires that the sign of $(\Omega - 1)$ must not change throughout the evolution of the universe so as to change the kind of the universe from one to another. That means in this theory, the universe has only one kind of curvature throughout its evolution and does not permit going from one
curvature into another. In other words the universe has been and will be in only one form of expansion. It is not obvious, however, that this is indeed a valid assumption whether theoretically or experimentally. As will be shown in the sequel, the universe has actually three phases of expansion, and it does go from one to the second and then to the third phase.

In the combined Friedmann-Lemaître theory discussed above in which both the matter density and the cosmological constant are not zero, nevertheless, the theory does permit the change of sign of the decelerating parameter \( q \), as can be seen from Fig. 4.1. There exist no equations, however, that describe this kind of transfer from one type of universe to another.

V. COSMOLOGICAL THEORY IN TERMS OF DISTANCE AND REDSHIFT

A new outlook at the universe expansion can be achieved and is presented here. The new theory has the following features: (1) It gives a direct relationship between distances and redshifts. (2) It is fully general relativistic. (3) It includes two universal constants, the speed of light in vacuum \( c \), and the Hubble time in the absence of gravity \( \tau \) (might also be called the Hubble time in vacuum). (4) The redshift parameter \( z \) is taken as the time-like coordinate. (5) The energy-momentum tensor is represented differently by including in it a term which is equivalent to the cosmological constant. And (6) it predicts that the universe has three phases of expansion: decelerating, constant and accelerating, but it is now in the stage of accelerating expansion phase after having gone through the other two phases.

Our starting point is Hubble’s cosmological equation of state, Eq. (1.1). One can keep the velocity \( v \) in equation (1.1) or replace it with the redshift parameter \( z \) by means of \( z = v/c \). Since \( \mathbf{R} = (x_1, x_2, x_3) \), the square of Eq. (1.1) then yields

\[
 c^2 H_0^{-2} z^2 - \left( x_1^2 + x_2^2 + x_3^2 \right) = 0. \tag{5.1}
\]

Our aim is to write our equations in an invariant way so as to enable us to extend them to curved space. Equation (5.1) is not invariant since \( H_0^{-1} \) is the Hubble time at present. At
the limit of zero gravity, Eq. (5.1) will have the form

\[ c^2 \tau^2 z^2 - \left( x_1^2 + x_2^2 + x_3^2 \right) = 0, \]  

(5.2)

where \( \tau \) is Hubble’s time in vacuum, which is a universal constant the numerical value of which will be determined in the sequel by relating it to \( H_0^{-1} \) at different situations. Equation (5.2) provides the basis of a cosmological special relativity and was investigated extensively [11-16].

In order to make Eq. (5.2) adaptable to curved space we write it in a differential form:

\[ c^2 \tau^2 dz^2 - \left( dx_1^2 + dx_2^2 + dx_3^2 \right) = 0, \]  

(5.3)

or, in a covariant form in flat space,

\[ ds^2 = \eta_{\mu\nu} dx^\mu dx^\nu = 0, \]  

(5.4a)

where \( \eta_{\mu\nu} \) is the ordinary Minkowskian metric, and our coordinates are \( (x^0, x^1, x^2, x^3) = (c\tau z, x_1, x_2, x_3) \). Equation (5.4a) expresses the null condition, familiar from light propagation in space, but here it expresses the universe expansion in space. The generalization of Eq. (5.4a) to a covariant form in curved space can immediately be made by replacing the Minkowskian metric \( \eta_{\mu\nu} \) by the curved Riemannian geometrical metric \( g_{\mu\nu} \),

\[ ds^2 = g_{\mu\nu} dx^\mu dx^\nu = 0, \]  

(5.4b)

obtained from solving the Einstein field equations.

Because of the spherical symmetry nature of the universe, the metric we seek is of the form [8]

\[ ds^2 = c^2 \tau^2 dz^2 - e^\lambda dr^2 - r^2 \left( d\theta^2 + \sin^2 \theta d\phi^2 \right), \]  

(5.5)

where co-moving coordinates, as in the Friedmann theory, are used and \( \lambda \) is a function of the radial distance \( r \). The metric (5.5) is static and solves the Einstein field equation (2.7). When looking for static solutions, Eq. (2.7) can also be written as

\[ e^{-\lambda} \left( \lambda' / r - 1/r^2 \right) + 1/r^2 = 8\pi G T_0^0, \]  

(5.6)
when $\Lambda$ is taken zero, and where a prime denotes differentiation with respect to $r$.

In general relativity theory one takes for $T^0_0 = \rho$. So is the situation in Newtonian gravity where one has the Poisson equation $\nabla^2 \phi = 4\pi G \rho$. At points where $\rho = 0$ one solves the vacuum Einstein field equations and the Laplace equation $\nabla^2 \phi = 0$ in Newtonian gravity. In both theories a null (zero) solution is allowed as a trivial case. In cosmology, however, there exists no situation at which $\rho$ can be zero because the universe is filled with matter. In order to be able to have zero on the right-hand side of Eq. (5.6) we take $T^0_0$ not as equal to $\rho$ but to $\rho - \rho_c$, where $\rho_c$ is chosen by us now as a constant given by $\rho_c = 3/8\pi G \tau^2$.

The introduction of $\rho_c$ in the energy-momentum tensor might be regarded as adding a cosmological constant to the Einstein field equations. But this is not exactly so, since the addition of $-\rho_c$ to $T^0_0$ means also fixing the numerical value of the cosmological constant and is no more a variable to be determined by experiment. At any rate our reasons are philosophically different from the standard point of view, and this approach has been presented and used in earlier work [17].

The solution of Eq. (5.6), with $T^0_0 = \rho - \rho_c$, is given by

$$e^{-\lambda} = 1 - (\Omega - 1) r^2/c^2 \tau^2,$$

(5.7)

where $\Omega = \rho/\rho_c$. Accordingly, if $\Omega > 1$ we have $g_{rr} = - (1 - r^2/R^2)^{-1}$, where

$$R^2 = c^2 \tau^2 / (\Omega - 1),$$

(5.8a)

exactly equals to $g_{11}$ given by Eq. (2.4) for the positive-curvature Friedmann universe that is obtained in the standard theory by purely geometrical manipulations (see Sect. 2). If $\Omega < 1$, we can write $g_{rr} = - (1 + r^2/R^2)^{-1}$ with

$$R^2 = c^2 \tau^2 / (1 - \Omega),$$

(5.8b)

which is equal to $g_{11}$ given by Eq. (2.5) for the negative-curvature Friedmann universe. In the above equations $r < R$. 

13
In Fig. 5.1 a plot of $R$ as a function of $\Omega$, according to Eqs. (5.8), is given. One can interpret $R$ as the boundary of the universe within which matter can exist, although it is not necessarily that the matter fills up all the space bounded by $R$.

Moreover, we know that the Einstein field equations for these cases are given by Eqs. (2.8) which, in our new notation, have the form

$$\left[(dR/dz)^2 + c^2 \tau^2\right]/R^2 = (\Omega - 1), \quad (5.9a)$$

$$\left[(dR/dz)^2 - c^2 \tau^2\right]/R^2 = (\Omega - 1). \quad (5.9b)$$

As is seen from these equations, if one neglects the first term in the square brackets with respect to the second ones, $R^2$ will be exactly reduced to their values given by Eqs. (5.9).

The expansion of the universe can now be determined from the null condition $ds = 0$, Eq. (5.4b), using the metric (5.5). Since the expansion is radial, one has $d\theta = d\phi = 0$, and the equation obtained is

$$dr/dz = c\tau \left[1 + (1 - \Omega) r^2/c^2 \tau^2\right]^{1/2}. \quad (5.10)$$

The second term in the square bracket of Eq. (5.10) represents the deviation from constant expansion due to gravity. For without this term, Eq. (5.10) reduces to $dr/dz = c\tau$ or $dr/dv = \tau$, thus $r = \tau v + \text{constant}$. The constant can be taken zero if one assumes, as usual, that at $r = 0$ the velocity should also vanish. Accordingly we have $r = \tau v$ or $v = \tau^{-1}r$. When $\Omega = 1$, namely when $\rho = \rho_c$, we have a constant expansion.

The equation of motion (5.10) can be integrated exactly by the substitutions

$$\sin \chi = \alpha r/c\tau; \ \Omega > 1, \quad (5.11a)$$

$$\sinh \chi = \beta r/c\tau; \ \Omega < 1, \quad (5.11b)$$

where

$$\alpha = (\Omega - 1)^{1/2}, \ \beta = (1 - \Omega)^{1/2}. \quad (5.12)$$

For the $\Omega > 1$ case a straightforward calculation, using Eq. (5.11a), gives

$$dr = (c\tau/\alpha) \cos \chi d\chi, \quad (5.13)$$
and the equation of the universe expansion (5.10) yields

\[ d\chi = \alpha dz. \quad (5.14a) \]

The integration of this equation gives

\[ \chi = \alpha z + \text{constant}. \quad (5.15a) \]

The constant can be determined, using Eq. (5.11a). For \( \chi = 0 \), we have \( r = 0 \) and \( z = 0 \), thus

\[ \chi = \alpha z, \quad (5.16a) \]

or, in terms of the distance, using (5.11a) again,

\[ r (z) = (c\tau/\alpha) \sin \alpha z; \ \alpha = (\Omega - 1)^{1/2}. \quad (5.17a) \]

This is obviously a decelerating expansion.

For \( \Omega < 1 \), using Eq. (5.11b), then a similar calculation yields for the universe expansion (5.10)

\[ d\chi = \beta dz, \quad (5.14b) \]

thus

\[ \chi = \beta z + \text{constant}. \quad (5.15b) \]

Using the same initial conditions used above then give

\[ \chi = \beta z, \quad (5.16b) \]

and in terms of distances,

\[ r (z) = (c\tau/\beta) \sinh \beta z; \ \beta = (1 - \Omega)^{1/2}. \quad (5.17b) \]

This is now an accelerating expansion.

For \( \Omega = 1 \) we have, from Eq. (5.10),

\[ d^2r/dz^2 = 0. \quad (5.14c) \]
The solution is, of course,

\[ r(z) = c\tau z. \]  

(5.17c)

This is a constant expansion.

It will be noted that the last solution can also be obtained directly from the previous two ones for \( \Omega > 1 \) and \( \Omega < 1 \) by going to the limit \( z \to 0 \), using L'Hospital lemma, showing that our solutions are consistent. It will be shown later on that the constant expansion is just a transition stage between the decelerating and the accelerating expansions as the universe evolves toward its present situation.

Figure 5.2 describes the Hubble diagram of the above solutions for the three types of expansion for values of \( \Omega \) from 100 to 0.24. The figure describes the three-phase evolution of the universe. Curves (1) to (5) represent the stages of decelerating expansion according to Eq. (5.17a). As the density of matter \( \rho \) decreases, the universe goes over from the lower curves to the upper ones, and it does not have enough time to close up to a big crunch. The universe subsequently goes to curve (6) with \( \Omega = 1 \), at which time it has a constant expansion for a fraction of a second. This then followed by going to the upper curves (7) and (8) with \( \Omega < 1 \) where the universe expands with acceleration according to Eq. (5.17b). A curve of this kind fits the present situation of the universe. For curves (1) to (4) in the diagram we use the cut off when the curves were at their maximum (or the same could be done by using the cut off as determined by \( R \) of Fig. 5.1). In Table 5.1 we present the cosmic times with respect to the big bang and the cosmic radiation temperature for each of the curves appearing in Fig. 5.2.

In order to decide which of the three cases is the appropriate one at the present time, we have to write the solutions (5.17) in the ordinary Hubble law form \( v = H_0 r. \) To this end we change variables from the redshift parameter \( z \) to the velocity \( v \) by means of \( z = v/c \) for \( v \) much smaller than \( c \). For higher velocities this relation is not accurate and one has to use a Lorentz transformation in order to relate \( z \) to \( v \). A simple calculation then shows that, for
receding objects, one has the relations

\[ z = [(1 + v/c) / (1 - v/c)]^{1/2} - 1, \tag{5.18a} \]

\[ v/c = z (z + 2) / \left(z^2 + 2z + 2\right). \tag{5.18b} \]

We will assume that \( v \ll c \) and consequently Eqs. (5.17) have the forms

\[ r (v) = \left(c\tau/\alpha\right) \sin (\alpha v/c), \tag{5.19a} \]

\[ r (v) = \left(c\tau/\beta\right) \sinh (\beta v/c), \tag{5.19b} \]

\[ r (v) = \tau v. \tag{5.19c} \]

Expanding now Eqs. (5.19a) and (5.19b) and keeping the appropriate terms, then yields

\[ r = \tau v \left(1 - \alpha^2 v^2/6c^2\right), \tag{5.20a} \]

for the \( \Omega > 1 \) case, and

\[ r = \tau v \left(1 + \beta^2 v^2/6c^2\right), \tag{5.20b} \]

for \( \Omega < 1 \). Using now the expressions for \( \alpha \) and \( \beta \), given by Eq. (5.12), in Eqs. (5.20) then both of the latter can be reduced into a single equation

\[ r = \tau v \left[1 + \left(1 - \Omega\right) v^2/6c^2\right]. \tag{5.21} \]

Inverting now this equation by writing it in the form \( v = H_0 r \), we obtain in the lowest approximation for \( H_0 \) the following:

\[ H_0 = h \left[1 - \left(1 - \Omega\right) v^2/6c^2\right], \tag{5.22} \]

where \( h = \tau^{-1} \). Using \( v \approx r/\tau \), or \( z = v/c \), we also obtain

\[ H_0 = h \left[1 - \left(1 - \Omega\right) r^2/6c^2 \tau^2\right] = h \left[1 - \left(1 - \Omega\right) z^2/6\right]. \tag{5.23} \]

Consequently, \( H_0 \) depends on the distance, or equivalently, on the redshift. As is seen, \( H_0 \) has meaning only for \( r \to 0 \) or \( z \to 0 \), namely when measured \textit{locally}, in which case it becomes \( h \).
VI. CONCLUDING REMARKS

In recent years observers have argued for values of $H_0$ as low as 50 and as high as 90 km/sec-Mpc, some of the recent ones show $80 \pm 17$ km/sec-Mpc [18-26]. There are the so-called “short” and “long” distance scales, with the higher and the lower values for $H_0$ respectively [27]. Indications are that the longer the distance of measurement the smaller the value of $H_0$. By Eqs. (5.22) and (5.23) this is possible only for the case in which $\Omega < 1$, namely when the universe is at an accelerating expansion. Figures 5.3 and 5.4 show the Hubble diagrams for the predicted by theory distance-redshift relationship for the accelerating expanding universe at present time, whereas figures 5.5 and 5.6 show the experimental results [28-29].

Our estimate for $h$, based on published data, is $h \approx 85 - 90$ km/sec-Mpc. Assuming $\tau^{-1} \approx 85$ km/sec-Mpc, Eq. (5.23) then gives

$$H_0 = h \left[1 - 1.3 \times 10^{-4} \left(1 - \Omega \right) r^2 \right],$$

where $r$ is in Mpc. A computer best-fit can then fix both $h$ and $\Omega$.

To summarize, a new general-relativistic theory of cosmology has been presented in which the dynamical variables are those of Hubble’s, i.e. distances and redshifts. The theory describes the universe as having a three-phase evolution with a decelerating expansion, followed by a constant and an accelerating expansion, and it predicts that the universe is now in the latter phase. As the density of matter decreases, while the universe is at the decelerating phase, it does not have enough time to close up to a big crunch. Rather, it goes to the constant expansion phase, and then to the accelerating stage.

The idea to express cosmological theory in terms of directly-measurable quantities, such as distances and redshifts, was partially inspired by Albert Einstein’s favourite remarks on the theory of thermodynamics in his Autobiographical Notes [30].

We wish to thank Professor Michael Gedalin for his help in preparing the diagrams.

Fig. 5.1 A plot of $R$ as a function of $\Omega$ according to equations (5.8). $R$ is the boundary of the universe within which matter can exist, although it is not necessarily that the matter fills up all the space bounded by $R$.

Fig. 5.2 Hubble’s diagram describing the three-phase evolution of the universe according to Einstein’s general relativity theory. Curves (1) to (5) represent the stages of decelerating expansion according to $r(z) = (c\tau/\alpha)\sin \alpha z$, where $\alpha = (\Omega - 1)^{1/2}$, $\Omega = \rho/\rho_c$, with $\rho_c$ a constant, $\rho_c = 3/(8\pi G \tau^2)$, and $c$ and $\tau$ are the speed of light and the Hubble time in vacuum (both universal constants). As the density of matter $\rho$ decreases, the universe goes over from the lower curves to the upper ones, but it does not have enough time to close up to a big crunch. The universe subsequently goes to curve (6) with $\Omega = 1$, at which time it has a constant expansion for a fraction of a second. This then followed by going to the upper curves (7)-(8) with $\Omega < 1$ where the universe expands with acceleration according to $r(z) = (c\tau/\beta)\sinh \beta z$, where $\beta = (1 - \Omega)^{1/2}$. One of these last curves fits the present situation of the universe.
