(Received 14 November 2019; published 13 January 2020)

Possible $N\Omega$-like dibaryons $N\Omega_{cc}$ and $N\Omega_{bb}$ are investigated within the framework of two quark models: the chiral quark model (ChQM) and quark delocalization color screening model (QDCSM). We find both of these two states are bound in these two models, and the binding energy increases as the quark of the system becomes heavier. In the ChQM, only coupling both color-singlet and hidden-color channels can make the $N\Omega_{cc}$ and $N\Omega_{bb}$ systems bound. While in the QDCSM, the attraction between $N$ and $\Omega_{cc}$ (or $\Omega_{bb}$) mainly comes from the kinetic energy term due to quark delocalization and color screening. The effect of channel coupling provides more effective attraction to $N\Omega_{cc}$ and $N\Omega_{bb}$ systems. Besides, the calculation of the low-energy scattering phase shifts, the scattering length, the effective range, and the binding energy (obtained from the scattering length) also supports the existence of the $N\Omega_{cc}$ and $N\Omega_{bb}$ states. All these properties can provide more information for experimental search for the $N\Omega$-like dibaryons with heavy quarks. And the experimental progress can also check the mechanism of the intermediate-range attraction of the baryon-baryon interaction in quark models.

I. INTRODUCTION

The study of dibaryons is one of the long-standing problems in hadron physics. Although research on the dibaryon has experienced several ups and downs in its long history, dibaryons have received renewed interest in recent years. For the nonstrange dibaryon, the best-known candidate is the $\Delta\Delta$ resonance state, which was predicted by Dyson and Xuong in 1964 [1] and later also by Goldman et al., who called it the “inevitable dibaryon” $d^*$ due to its unique symmetry features [2]. Recently, the WASA-at-COSY collaboration reported the discovery of this $\Delta\Delta$ resonance state with $M = 2.37$ GeV, $\Gamma \approx 70$ MeV, and $\lambda J^P = 0^+$ [3–5]. The detail of this dibaryon observation can be found in Ref. [6]. The quark model calculations [7–10], as well as the relativistic three-body calculations [11,12] all described properly the characteristics of this resonance.

For the strange dibaryon, the $H$-dibaryon with $J = 0, S = -2$, the $N\Omega$ with $J = 2, S = -3$, and the $\Omega\Omega$ with $J = 0, S = -6$ are particularly interesting, since the Pauli blocking among valence quarks do not operate in these systems. Above all, the progress of the $N\Omega$ searches in experiment attracted more and more attention for this state. Very recently, the measurement of the $p\Omega$ correlation function was conducted in Au + Au collisions by the STAR experiment at the Relativistic Heavy Ion Collider (RHIC) [13], and the result indicated that the scattering length is positive for the $p\Omega$ interaction and favored the $p\Omega$ bound-state hypothesis.

On the theoretical side, the $N\Omega$ state has been investigated by several groups. Goldman et al. predicted that the $S = -3, I = 1/2; J = 2$ dibaryon state $N\Omega$ might be a narrow resonance in a relativistic quark model [14]. Oka proposed that there should be a quasibound state with $IJ^P = \frac{1}{2}^+$ by using a constituent quark model [15]. Recent study of $\Omega$-like dibaryons with heavy quarks with $m_\Omega \approx 146$ MeV and $m_K \approx 525$ MeV [17]. K. Morita et al. studied the two-pair momentum correlation functions of the dibaryon candidate $N\Omega$ in relativistic heavy-ion collisions by employing the interactions obtained from the $\Omega$-like lattice QCD simulations [18,19]. Besides, this state has also been observed to be bound in several relativistic quark models [20–24].

For the dibaryons with heavy quarks, the $N\Lambda_c$ system and the $H$-like dibaryon state $\Lambda_c\Lambda_c$ were both studied on the hadron level [25,26] and on the quark level [27,28]. The possibility of existing deuteron-like dibaryons with heavy quarks, such as $N\Xi_c', N\Xi_c, N\Sigma_c, \Xi\Sigma_c$, and so on, were investigated by several realistic phenomenological nucleon-nucleon interaction models [29,30]. Recently many near-threshold charmonium-like states called $XYZ$ particles were observed, triggering many studies on the molecule-like bound states containing heavy-quark hadrons. Such studies will give further information on the hadron-hadron interactions. In the heavy-quark sector, the large masses of the heavy quarks reduce the kinetic energy of the
system, which makes them easier to form bound states. Very recently, the lattice QCD also studied the deuteron-like dibaryons with heavy quarks, which include valence quark contents: $\Sigma$, $\Xi_{cc}(uuccuu)$, $\Sigma_{cc}(uuccuu)$, $\Sigma_{bb}(uububb)$, $\Omega_{ccbb}(ssbb)$, and $\Omega_{ccbb}(ccbb)$ and with spin-parity $J^P = 1^-$ [31]. They also found that the binding of these dibaryons became stronger as they became heavier in mass. Therefore, the dibaryons with heavy quarks are also possible multiquark states, and the study of such system will help us to understand the hadron-hadron interactions and search for exotic quark states in temporary hadron physics.

It is known to all that QCD is the fundamental theory of the strong interaction in the perturbative region. However, in the low-energy region, it is difficult to directly use QCD to study complicated systems such as hadron-hadron interactions and multiquark states because of the nonperturbative complication. Various QCD-inspired models have been developed to get physical insights into the multiquark systems. The quark delocalization color screening model (QDCSM), developed in the 1990s with the aim of explaining the similarities in the heavy quark sector, has become one of the representations of the quark models. In this model, quarks confined in one nucleon are allowed to delocalize to a nearby baryon and the confinement interaction between quarks in different baryon orbits is modified to include a color screening factor. The latter is a model description of the hidden-color-channel coupling effect [33]. The delocalization parameter is determined by the dynamics of the interacting quark system; this allows the quark system to choose the most favorable configuration through its own dynamics in a larger Hilbert space. The model gives a good description of $N\Lambda$ and $YN$ interactions and the properties of deuteron [34,35]. It is also employed to study the dibaryon candidates $d^*$ [7,8] and $N\Omega$ [20–23] and dibaryons with heavy quarks, the $N\Lambda_c$ system and the $\Lambda_c$, $\Lambda_c$ system [27,28].

Another commonly used quark model is the chiral quark model (ChQM) [36,37], in which the constituent quarks interact with each other through colorless Goldstone boson exchange in addition to the colorful one-gluon exchange and color confinement. In this model, the chiral partner $\sigma$ meson exchange is introduced to obtain the immediate-range attraction of $NN$ interaction. We have shown that the $NN$ intermediate-range attraction mechanism in the QDCSM, quark delocalization and color screening, is equivalent to $\sigma$ meson exchange in the ChQM [35]. When extending to the $N\Omega$ system [23], the ChQM only has Goldstone boson exchange, since the $\sigma$ meson should not exchange between $u(d)$ and $s$ quark. The ChQM can accommodate a bound $N\Omega$ state only if both the color-singlet and hidden-color-channels coupling is considered. On the other hand, the QDCSM predicts there will be a bound $N\Omega$ state with only color-singlet-channels coupling. This indicates that the quark delocalization and color screening with the five-color-singlet-channels coupling provides enough effective attraction to bind the $N\Omega$ system.

In this work, we continue to investigate dibaryons with heavy quarks by using these two models. In our previous work, we have shown $N\Omega$ is a narrow resonance in the $\Lambda\Xi$ D-wave scattering process [22]. However, $\Lambda\Xi$ scattering data analysis is quite complicated. Then we calculated the low-energy $N\Omega$ scattering phase shifts, scattering length, effective range, and binding energy, which can be observed by the $N$-$\Omega$ correlation analysis with RHIC and large hadron collider (LHC) data or by the new developed automatic scanning system at Japan proton accelerator research complex (J-PARC) [23]. It is interesting to extend such study to the dibaryons on heavy quark sector. So we investigate whether the $N\Omega$-like dibaryons $N\Omega_{cc}$ and $N\Omega_{bb}$ exist or not in quark models. The low-energy scattering phase shifts, scattering length, effective range, and binding energy of $N\Omega_{cc}$ and $N\Omega_{bb}$ may also be useful for the experimental search of such heavy dibaryons. Besides, by comparing the results within two quark models, we can check the model dependence of the dibaryons prediction.

The structure of this paper is as follows. A brief introduction of two quark models is given in Sec. II. Section III devotes to the numerical results and discussions. The summary is shown in the last section.

## II. TWO QUARK MODELS

As mentioned above, we use two quark models, the ChQM and QDCSM, to study $N\Omega$-like dibaryons with heavy quarks.

### A. Chiral quark model

The chiral quark model can give a good description of the hadron spectra, nucleon-nucleon interaction, and multiquark states. In this model, the constituent quarks interact with each other through Goldstone boson exchange and one-gluon exchange in addition to color confinement. The model details can be found in Ref. [37]. Here we only give the Hamiltonian:

$$
H = \sum_{i=1}^{6} \left( m_i + \frac{p_i^2}{2m_i} \right) - T_{c.m.} + \sum_{j=1}^{6} \left( V_{ij}^C + V_{ij}^G + V_{ij}^F + V_{ij}^F \right),
$$

$$
V_{ij}^C = -a_i \Lambda_j \cdot \Lambda_j (r_{ij}^2 + v_0),
$$

$$
V_{ij}^G = \frac{1}{4} a_i \Lambda_j \cdot \Lambda_j \left[ \frac{1}{2} - \frac{\pi}{2} \delta(r_{ij}) \left( \frac{1}{m_i^2} + \frac{1}{m_j^2} + \frac{4\sigma_i \cdot \sigma_j}{3m_im_j} \right) - \frac{3}{4m_im_jr_{ij}^2} S_{ij} \right],
$$

$$
V_{ij}^F = V_s(r_{ij}) \sum_{a=1}^{3} \lambda_i^a \cdot \lambda_j^a + V_K(r_{ij}) \sum_{a=4}^{7} \lambda_i^a \cdot \lambda_j^a + V_\theta(r_{ij}) \left( \lambda_i^8 \cdot \lambda_j^8 \cos \theta_P - (\lambda_i^0 \cdot \lambda_j^0) \sin \theta_P \right)
$$
\[
V_x(r_{ij}) = \frac{g_{ch}^2}{4\pi} \frac{m_x}{12m_{ij}} \frac{\Lambda_x^2}{\Lambda_x^2 - m_x^2} \frac{Y(m_x r_{ij})}{\Lambda_x^2} + \left[ H(m_x r_{ij}) - \frac{\Lambda_x^3}{m_x^2} H(\Lambda_x r_{ij}) \right] S_{ij}, \quad \chi = \pi, K, \eta, \quad \alpha = 1, 2, \ldots
\]

where \( S_{ij} \) is the quark tensor operator; \( Y(x) \) and \( H(x) \) are standard Yukawa functions; \( T_{cm} \) is the kinetic energy of the center of mass; \( \alpha_{ch} \) is the chiral coupling constant, determined as usual from the \( \pi \)-nucleon coupling constant; and \( \alpha_2 \) is the quark-gluon coupling constant. In order to cover the wide energy range from light to strange to heavy quarks, an effective scale-dependent quark-gluon coupling \( \alpha_s(u) \) was introduced [38]:

\[
\alpha_s(u) = \frac{\alpha_0}{\ln \left( \frac{m_{QG}^2}{\Lambda_0^2} \right)}. \tag{9}
\]

The other symbols in the above expressions have their usual meanings. Here we should mention that the \( \sigma \) meson is restricted to exchange between the \( u \) and/or \( d \) quark pair only. The parameters are taken from our previous work [23], except the mass of heavy quarks, which are determined by fitting the masses of charm and bottom baryons.

**B. The quark delocalization color screening model**

The Hamiltonian of the QDCSM is almost the same as that of the ChQM, except for two modifications [32,34]. First, there is no \( \sigma \)-meson exchange in the QDCSM. Second, the screened color confinement is used between quark pairs reside in different baryon orbits. That is

\[
V_{ij}^C = \begin{cases} 
-a_2 \lambda_i^c \cdot \lambda_j^c (r_{ij} + u_0) & \text{if } i, j \text{ in the same baryon orbit} \\
-a_2 \lambda_i^c \cdot \lambda_j^c \left( \frac{1 - e^{-m_{ij} r_{ij}^2}}{m_{ij}} + u_0 \right) & \text{otherwise}
\end{cases} \tag{10}
\]

| \( b \) (fm) | \( m_{ud} \) (MeV) | \( m_s \) (MeV) | \( m_t \) (MeV) | \( m_b \) (MeV) |
|----------------|----------------|----------------|----------------|----------------|
| ChQM 0.518     | 313            | 536            | 1744           | 5100           |
| QDCSM 0.518    | 313            | 536            | 1744           | 5100           |

\[ V_{ij} = \frac{g_{ch}^2}{4\pi} \frac{m_x}{12m_{ij}} \frac{\Lambda_x^2}{\Lambda_x^2 - m_x^2} Y(m_x r_{ij}) - \frac{\Lambda_x^3}{m_x^2} \left[ H(m_x r_{ij}) - \frac{\Lambda_x^3}{m_x^2} H(\Lambda_x r_{ij}) \right] S_{ij}, \quad \chi = \pi, K, \eta, \]

\[ H(x) = (1 + 3/x + 3/x^2)Y(x), \quad Y(x) = e^{-x}/x, \]

All parameters, which are fixed by fitting to the masses of baryons with light flavors and heavy flavors, are taken from our previous work [28]. The values of the parameters of two models are listed in Table I. The masses of light flavor baryons are shown in our former work [23]; here we just list the masses of the charm and bottom baryons in Table II.

The quark delocalization in the QDCSM is realized by specifying the single-particle orbital wave function of the QDCSM as a linear combination of left and right Gausians, the single-particle orbital wave functions used in the ordinary quark cluster model,

\[ (1) \]

\[ \psi_{\alpha}(s_i, \epsilon) = [\phi_{\alpha}(s_i) + \epsilon \phi_{\alpha}(-s_i)] / N(\epsilon), \]

\[ \psi_{\beta}(-s_i, \epsilon) = [\phi_{\beta}(-s_i) + \epsilon \phi_{\beta}(s_i)] / N(\epsilon), \]

\[ N(\epsilon) = \sqrt{1 + \epsilon^2 + 2\epsilon e^{\epsilon^2/4b^2}}, \]

\[ \phi_{\alpha}(s_i) = \left( \frac{1}{\pi b^2} \right)^{3/4} e^{-\frac{\epsilon^2}{\pi b^2}} \left( \frac{1}{\pi b^2} \right)^{3/4} e^{-\frac{\epsilon^2}{\pi b^2}}. \]

Here \( s_i, i = 1, 2, \ldots, n \) are the generating coordinates, which are introduced to expand the relative motion wave function. The delocalization parameter \( \epsilon(s_i) \) is determined by the dynamics of the quark system rather than adjusted parameters. In this way, the system can choose its most favorable configuration through its own dynamics in a larger Hilbert space. It has been used to explain the crossover transition between hadron phase and quark-gluon plasma phase [40].

III. THE RESULTS AND DISCUSSIONS

In this work, we investigate the $N\Omega$-like dibaryons with heavy quarks; $N\Omega_{ccc}$ and $N\Omega_{bab}$ systems with quantum numbers $I^G = \frac{1}{2}^+$ in two quark models: the ChQM and QDCSM. The effects of channel coupling are studied here, both color-singlet channels (the color symmetry of the $3q$ cluster is [21]) and hidden-color channels (the color symmetry of the $3q$ cluster is [111]) are included. The labels of the hidden-color $3q$ cluster can be found in Ref. [23]. Here we list all 16 coupled channels of the $N\Omega_{ccc}$ system in Table III, where the first 5 channels are color-singlet channels and the last 11 ones are hidden-color channels.

To check whether there is any bound state, a dynamical calculation is needed. The resonating group method (RGM) [41] is employed here. By expanding the relative motion energy term due to quark delocalization and color screening, which work together to provide short-range repulsion and intermediate-range attraction.

In our previous work, we also calculated the low-energy scattering phase shifts, scattering length, and effective range of $N\Omega$, which can provide necessary information for $N-\Omega$ correlation analysis with RHIC and LHC data. Naturally, we do the same calculation for the $N\Omega_{ccc}$ and $N\Omega_{bab}$ systems. The consistent with our previous study of $N\Omega$ system [23], in which we found that the QDCSM with color-singlet-channels coupling obtained similar results to that of the ChQM with both color-singlet and hidden-color-channels coupling.

To understand the interaction between $N$ and $\Omega_{ccc}$, we study the effective potentials, as well as the contribution of each interaction term to the energy of the system. In the ChQM, the confinement, the one-gluon exchange, does not contribute to the effective potential between $N$ and $\Omega_{ccc}$, because there is no quark exchange between these two baryons. The $\pi$, $K$, $\eta$, and $\sigma$ mesons do not contribute either because they do not exchange between the $u(d)$ and $c$ quarks. There is only kinetic energy, which provide the repulsive interactions between $N$ and $\Omega_{ccc}$. That is why the individual $N\Omega_{ccc}$ channel is unbound in the ChQM.

Things are different in the QDCSM. The quark exchange happens between $N$ and $\Omega_{ccc}$, due to quark delocalization. The total effective potentials and the contributions of all interaction terms, including the kinetic energy ($V_{\text{kin}}$), the confinement ($V_{\text{con}}$), the one-gluon exchange ($V_{\varphi}$), the $\pi$ exchange ($V_{\pi}$), and the $\eta$ exchange ($V_{\eta}$), to the effective potential are shown in Fig. 1. We notice that, due to the special quark content of $N\Omega_{ccc}$ system, the effective interactions have very small contributions from the one-gluon-exchange interaction. The attraction of the $N\Omega_{ccc}$ state mainly comes from the kinetic energy term due to quark delocalization and color screening, and other terms provide repulsive potentials, which reduce the total attraction of the $N\Omega_{ccc}$ potential. By comparing with the interaction between $N$ and $\Omega$ [23], this behavior is similar. The intermediate-range attraction in the QDCSM comes from quark delocalization and color screening, which work together to provide short-range repulsion and intermediate-range attraction.

In our previous work, we also calculated the low-energy scattering phase shifts, scattering length, and effective range of $N\Omega$, which can provide necessary information for $N-\Omega$ correlation analysis with RHIC and LHC data. Naturally, we do the same calculation for the $N\Omega_{ccc}$ and $N\Omega_{bab}$ systems. The

TABLE IV. The binding energies of the $N\Omega_{ccc}$ system with channel coupling.

| Channel | $B_{cc}$ (MeV) | $B_{ccc}$ (MeV) | $B_{6cc}$ (MeV) |
|---------|----------------|----------------|----------------|
| ChQM    | $-0.6$         | $-30.9$        | $-16.4$       |
| QDCSM   |                |                |                |
The wave function of the dibaryon system is of the form
\[
\Psi = A[\hat{\phi}_A(\xi_1, \xi_2)\hat{\phi}_B(\xi_3, \xi_4)\chi_L(R_{AB})],
\]
where \(\xi_1\) and \(\xi_2\) are the internal coordinates for the baryon cluster \(A\) and \(\xi_3\) and \(\xi_4\) are the internal coordinates for another baryon cluster \(B\). \(R_{AB} = R_A - R_B\) is the relative coordinate between the two clusters. The symbol \(A\) is the antisymmetrization operator; \(\hat{\phi}_A\) and \(\hat{\phi}_B\) are the internal cluster wave functions of two baryons, \(A\) and \(B\), and \(\chi_L(R_{AB})\) is the relative motion wave function between two clusters. For a scattering problem, \(\chi_L(R_{AB})\) is expanded as
\[
\chi_L(R_{AB}) = \sum_{i=1}^{n} C_i \frac{\tilde{u}_L(R_{AB}, S_i)}{R_{AB}} Y_{LM}(\mathbf{R}_{AB})
\]
with
\[
\tilde{u}_L(R_{AB}, S_i) = \begin{cases} 
\alpha_i u_L(R_{AB}, S_i), & R_{AB} \leq R_C \\
\left[\hbar_L^2(k_{AB}, R_{AB}) - s_i \hbar_L^2(k_{AB}, R_{AB})\right], & R_{AB} > R_C
\end{cases}
\]
where \(u_L(R_{AB}, S_i) = \sqrt{\frac{4\pi}{2\pi b_x^2}}^\frac{3}{4} R_{AB} \times \exp\left[-\frac{3}{4b_x^2}(R_{AB}^2 - S_i^2)\right]\]
\[\left(j_l^L \left(-i \frac{3}{2b_x^2} R_{AB} S_i\right)\right),\]
where \(S_i\) is the generating coordinate, \(C_i\) are expansion coefficients, and \(n\) is the number of the Gaussian bases, which is determined by the stability of the results. In addition, \(\hbar_L^2\) are the \(L\)th spherical Hankel functions, \(k_{AB}\) is the momentum of relative motion with \(k_{AB} = \sqrt{2\mu_{AB}E_{cm}}\), \(\mu_{AB}\) is the reduced mass of two hadrons (\(A\) and \(B\)) of the open channel, \(E_{cm}\) is the incident energy, and \(R_C\) is a cutoff radius beyond which all the strong interaction can be disregarded. Also, \(\alpha_i\) and \(s_i\) are complex parameters which are determined by the smoothness condition at \(R_{AB} = R_C\) and \(C_i\) satisfy \(\sum_{i=1}^{n} C_i = 1\); \(j_L\) is the \(L\)th spherical Bessel function. After performing variational procedure, a \(L\)th partial-wave equation for the scattering problem can be deduced as
\[
\sum_{j=1}^{n} L_{ij}^L C_j = M_i^L \quad (i = 0, 1, \ldots, n - 1),
\]
with
\[
L_{ij}^L = \kappa_{ij}^L - \kappa_{00}^L + \kappa_{ij}^L,
\]
\[
M_i^L = \kappa_{00}^L - \kappa_{00}^L,
\]
and
\[
\kappa_{ij}^L = \left(\hat{\phi}_A(\xi_1, \xi_2)\hat{\phi}_B(\xi_3, \xi_4)\tilde{u}_L(R_{AB}', S_i)\right) \frac{R_{AB}'}{R_{AB}} Y_{LM}(\mathbf{R}_{AB}')
\]
\[\left[H - E\right]
\[\mathcal{A}\left[\hat{\phi}_A(\xi_1, \xi_2)\hat{\phi}_B(\xi_3, \xi_4)\tilde{u}_L(R_{AB}', S_i)\right] \frac{R_{AB}'}{R_{AB}} Y_{LM}(\mathbf{R}_{AB})\].
become heavier. and found that the stability of dibaryons increases as they studied the deuteron-like dibaryons with heavy quarks.

\[ N_{\Omega_{BB}} \]

From Table V, we can see that the scattering length consistent with the recent work of lattice QCD in which the quark of the system becomes heavier. This conclusion is positive, which implies again that this state is a bound state. The binding energy \( B' \) of this state is close to the binding energy \( B \) obtained in the bound-state calculations shown above. It indicates that the binding energy from the two methods are coincident with each other.

Particularly, we also extend the study to the \( N_{\Omega_{BB}} \) system because of the heavy flavor symmetry. The numerical results are listed in Table VI and Table VII. The phase shifts of the \( N_{\Omega_{BB}} \) state in both the ChQM and QDCSM are shown in Fig. 3. The results are similar to the \( N_{\Omega_{CC}} \) system. The \( N_{\Omega_{BB}} \) state is bound in the ChQM by coupling all color-singlet and hidden-color channels, and it is also bound in the QDCSM with color-singlet-channels coupling only. The low-energy phase shifts, the scattering length, the effective range, as well as the binding energy \( B' \) also favor the existence of the \( N_{\Omega_{BB}} \) bound state. Besides, by comparing with the dibaryon \( N\Omega \) and \( N_{\Omega_{CC}} \), we find that the binding energy increases as the quark of the system becomes heavier. This conclusion is consistent with the recent work of lattice QCD, in which they studied the deuteron-like dibaryons with heavy quarks and found that the stability of dibaryons increases as they become heavier.

**IV. SUMMARY**

In this work, we investigate the \( N\Omega \)-like dibaryons with heavy quarks: \( N_{\Omega_{CC}} \) and \( N_{\Omega_{BB}} \) systems with quantum numbers \( I^G = \frac{1}{2}^+ \) in the framework of two quark models: the ChQM and QDCSM. Our results show that both of these two states are bound in two models. However, the factors leading to such bound states are different. In the ChQM, the confinement, one-gluon exchange, as well as the \( \pi, K, \eta, \) and \( \sigma \) mesons, do not contribute to the effective potential between \( N \) and \( \Omega_{CC} \) (or \( \Omega_{BB} \)), due to the special quark content of \( N_{\Omega_{CC}} \) and \( N_{\Omega_{BB}} \) systems. Only coupling all color-singlet and hidden-color channels can make the \( N_{\Omega_{CC}} \) and \( N_{\Omega_{BB}} \) systems bound. Whereas in the QDCSM, the attraction between \( N \) and \( \Omega_{CC} \) (or \( \Omega_{BB} \)) mainly comes from the kinetic energy term due to quark delocalization and color screening. Besides, the channel coupling of color-singlet channels also plays an important role for providing more effective attraction to the \( N_{\Omega_{CC}} \) and \( N_{\Omega_{BB}} \) systems. This behavior of these two states is similar to that of the \( N\Omega \) system. The study of the \( N\Omega \) system, as well as the \( N_{\Omega_{CC}} \) and \( N_{\Omega_{BB}} \) systems, opens a new window to investigate the hadron-hadron interaction. Considerable headway in the search for the \( N\Omega \) bound state was made by the STAR experiment. If the existence of the \( N\Omega \) state can be confirmed by experiments, it will be a signal showing that the mechanism of quark delocalization and color screening is really responsible for the intermediate-range attraction of the baryon-baryon interaction.

By comparing the results of the \( N\Omega \), \( N_{\Omega_{CC}} \), and \( N_{\Omega_{BB}} \) states, we find that the binding of these dibaryons becomes stronger as they become heavier, which indicates that it is more possible for the \( N_{\Omega_{CC}} \) and \( N_{\Omega_{BB}} \) states to be bound. So it is worth looking for such \( N\Omega \)-like dibaryons in the experiments, although it will be a challenging subject because of their low production yields. It is expected that the calculated the low-energy scattering phase shifts (the scattering length, the effective range, and the binding energy) are beneficial to the experimental search for \( N\Omega \)-like dibaryons in the two-baryon correlation analysis approach.

**TABLE VI.** The binding energies of the \( N_{\Omega_{BB}} \) system with channel coupling.

|          | \( B_{cc} \) (MeV) | \( B_{cc'} \) (MeV) | \( B_{16cc'} \) (MeV) |
|----------|------------------|------------------|------------------|
| ChQM     | ub               | ub               | −16.4            |
| QDCSM    | ub               | −50.7            | −16.4            |

**TABLE VII.** The scattering length \( a_0 \), effective range \( r_0 \), and binding energy \( B' \) of the \( N_{\Omega_{BB}} \) state.

|          | \( a_0 \) (fm) | \( r_0 \) (fm) | \( B' \) (MeV) |
|----------|--------------|--------------|-------------|
| ChQM     | 1.5981       | 0.66427      | −40.1       |
| QDCSM    | 1.1608       | 0.53617      | −40.1       |
