Abstract

In this paper, we propose a robust and efficient numerical method to compute the dynamics of the rotating two-component dipolar Bose-Einstein condensates (BEC). Using the rotating Lagrangian coordinates transform \cite{13}, we reformulate the original coupled Gross-Pitaevskii equations (CGPE) into new equations where the rotating term vanishes and the potential becomes time-dependent. A time-splitting Fourier pseudospectral method is proposed to simulate the new equations where the nonlocal Dipole-Dipole Interactions (DDI) are computed by a newly-developed Gaussian-sum (GauSum) solver \cite{22} which helps achieve spectral accuracy in space within $O(N \log N)$ operations ($N$ is the total number of grid points). The new method is spectrally accurate in space and second order accurate in time, and the accuracies are confirmed numerically. Dynamical properties of some physical quantities, including the total mass, energy, center of mass and angular momentum expectation, are presented and confirmed numerically. Interesting dynamics phenomena that are peculiar to the rotating two-component dipolar BECs, such as dynamics of center of mass, quantized vortex lattices dynamics and the collapse dynamics of 3D cases, are presented.

temperatures and at different trapping potentials have been investigated in the physics community [25, 48, 52, 53, 56]. At early stage, it was apparent that the isotropic s-wave short-range interatomic interactions govern most of the observed phenomena [11]. However, recent successful realisation of BECs in the degenerate gas of dipolar bosons [27, 37, 6] have shown that the properties of dipolar BECs are well described by the macroscopic complex-valued wave function \( \psi \) whose evolution is governed by the celebrating three-dimensional (3D) coupled Gross–Pitaevskii equations (CGPE) with DDI term. Moreover, the 3D CGPE can be reduced to an effective two-dimensional (2D) equation that describes the strength of DDI and \( \delta \) is a given real-valued external trapping potential. The constant \( \beta_{jk} \) describes the strength of the short-range interactions in a condensate (positive/negative for repulsive/attractive interaction), \( L_z = -i(x\partial_y - y\partial_x) = -i\partial_y \) is the z-component of the angular momentum and \( \Omega \) represents the rotating frequency. \( V_j(x) \) is a given real-valued external trapping potential determined by the type of system under investigation. In most BEC experiments, a harmonic potential is chosen to trap the condensates, i.e. for \( j = 1, 2 \)

\[
V_j(x) = \frac{1}{2} \sum_{\substack{\alpha, \beta = x, y, z \in \mathbb{R}^d, \ t \geq 0}} \left( \gamma_{\alpha, j} x^2 + \gamma_{\beta, j} y^2 + \gamma_{z, j} z^2 \right)
\]

where \( \gamma_{v,j} (v = x, y, z) \) are dimensionless constants representing the trapping frequencies in v-direction. Moreover, \( \lambda_{ij} (i, j = 1, 2) \) is a constant characterizing the strength of DDI and \( U_{\text{dip}}(x) \) is the long-range DDI potential. In 3D, \( U_{\text{dip}}(x) \) reads as

\[
U_{\text{dip}}(x) = \frac{3}{4\pi|x|^3} \left[ 1 - \frac{3(x \cdot n)^2}{|x|^2} \right] = -\delta(x) - 3 \partial_{nn} \left( \frac{1}{4\pi|x|^3} \right), \quad x \in \mathbb{R}^3,
\]

1. Introduction

The Bose-Einstein condensation (BEC) provides an incredible glimpse into the macroscopic quantum world and has been extensively studied since its first experimental creation in 1995 [3, 17, 21]. A subsequent achievement of quantum vortices in rotating BECs [11, 35, 24] broadens the attention to explore vortex states and their dynamics associated with superfluidity. At early stage, it was apparent that the isotropic s-wave short-range interatomic interactions govern most of the observed phenomena [11]. However, recent successful realisation of BECs in the degenerate gas of dipolar bosons [27, 37, 6] have shown that the properties of multi-component system admits novel and fundamentally different scenarios such as the domain walls, vortons and square vortex lattices [30, 32, 18]. As the simplest case, the two-component BECs provides a good opportunity to investigate the properties of multi-component condensates.

Very recently, several studies related to the vortices of rotating two-component dipolar BECs under different trapping potentials have been investigated in the physics community [25, 35, 52, 33, 54]. At temperatures \( T \) much smaller than the critical temperature \( T_c \), the properties of rotating two-component dipolar BECs are well described by the macroscopic complex-valued wave function \( \Psi = (\psi_1(x, t), \psi_2(x, t))^T \) whose evolution is governed by the governing three-dimensional (3D) coupled Gross–Pitaevskii equations (CGPE) with DDI term. Moreover, the 3D CGPE can be reduced to an effective two-dimensional (2D) equation if the external potential is highly strong in z-direction [35, 10]. In a unified way, the \( d \)-dimensional (\( d = 2 \) or 3) dimensionless CGPE with DDI term reads as [35, 18, 19, 50, 6]:
with \( \mathbf{n} = (n_1, n_2, n_3)^T \), a given unit vector i.e. \( |\mathbf{n}(t)| = \sqrt{n_1^2 + n_2^2 + n_3^2} = 1 \), representing the dipole axis (or dipole moment), \( \partial_n = \mathbf{n} \cdot \nabla \) and \( \partial_{nn} = \partial_n (\partial_n) \). While in 2D, it is defined as \[ \Phi_j(x) = -\rho_j - 3 \partial_n \partial_n \left( \frac{1}{4\pi|x|} \star \rho_j \right) = -\rho_j - 3 \frac{1}{4\pi|x|} \star (\partial_n \rho_j), \quad x \in \mathbb{R}^2, \] while the 2D DDI (1.5) is rewritten as

\[ \Phi_j(x) = -\rho_j - 3 \frac{1}{2} |\nabla_j| \star \left( (\partial_n \rho_j) - n_j^2 |\nabla_j|^2 \right), \quad x \in \mathbb{R}^2. \]}

The CGPE in (1.1)–(1.2) conserve two important quantities: the mass (or normalization) of the wave function

\[ \mathcal{N}_j(t) := \int_{\mathbb{R}^d} |\psi_j(x,t)|^2 dx, \quad j = 1, 2, \quad t \geq 0, \] and the energy per particle

\[ \mathcal{E}(\Psi(\cdot,t)) = \int_{\mathbb{R}^d} \int_{\mathbb{R}^d} \left( \frac{1}{2} \sum_{j=1}^2 \left| \nabla \psi_j \right|^2 + V_j(\cdot)|\psi_j|^2 + \frac{\beta_{j1}}{2} |\psi_j|^4 + \frac{\lambda_{j2}}{2} \Phi_j |\psi_j|^2 - \Omega \psi_j^* L_3 \psi_j \right) dx \] \[ \quad + \frac{1}{2} \left( \beta_{12} + \beta_{21} \right) |\psi_1|^2 |\psi_2|^2 + \frac{1}{4} \left( \lambda_{12} + \lambda_{21} \right) (\Phi_1 |\psi_1|^2 + \Phi_2 |\psi_1|^2) \] \[ \quad \equiv \mathcal{E}(\Psi(\cdot,0)), \quad t \geq 0. \]

It is easy to check that the mass of each component is also conserved, i.e.

\[ \mathcal{N}_j(t) := |||\psi_j(t)||| = \int_{\mathbb{R}^d} |\psi_j(x,t)|^2 dx = |||\psi_j(0)|||^2, \quad j = 1, 2, \quad t \geq 0. \]
GauSum solver are fast algorithms with a complexity of $O(N \log N)$ where $N$ is the total number of grid points. Compared with the NUFFT solver, the GauSum solver is 3-5 times faster, thus it is an ideal candidate for applications [5]. For the rotation term, Bao et al. [13] developed a rotating Lagrangian coordinates transformation method to reformulate the rotating term into a time-dependent trapping potential, and this method allows for the implementation of high order time marching numerical schemes [39, 16, 4].

The main objectives of this paper are threefold.

1. Using the rotating Lagrangian coordinates transform [13], we reformulate the original CGPE into new equations without rotating term. Then we develop a robust and efficient numerical method to compute dynamics of the new equations by incorporating the GauSum solver [22], which is designed to compute the nonlocal DDI, into an adapted version of the time-splitting Fourier pseudospectral method. Detailed numerical results are reported to confirm the spectral accuracy in space and second order temporal accuracy of the proposed method in 2D and 3D respectively.

2. Develop the dynamical laws for the mass and energy, the angular momentum expectation and center of mass, together with some proofs. An analytical solution with special initial data is also presented.

3. Apply our method to study the dynamics of center of mass, quantized vortex lattices and non-rotating dipolar BECs under different setups. In particular, phase separation and collapse dynamics are observed numerically for the 3D cases.

The rest of the paper is organized as follows. In Section 2, we present a brief review of the Gaussian-sum method. In Section 3, we derive some dynamical laws for some physical quantities that are usually considered for the standard GPE. We then propose an efficient and robust time splitting Fourier pseudospectral numerical method for the dynamics simulation. Detailed accuracy tests are presented in Section 4 to confirm the spatial and temporal accuracy of our method, and some interesting numerical results are also reported. Finally, a conclusion is drawn in Section 5.

2. The DDI evaluation by Gaussian-sum method

In the CGPE (1.1)–(1.2), due to presence of the confining potential, the density $\rho(x) := |\psi(x)|^2$ is usually smooth and decays exponentially fast. As is shown by (1.6) and (1.7), the DDI computation boils down to Coulomb potential evaluation. Therefore, in this section, we shall only give a brief self-contained review of the GauSum method [22] for Coulomb potential. All subscripts in the section are omitted for brevity.

To start with, we first truncate the whole space to a bounded domain, e.g. a square box $B_L := [-L, L]^d$, then rescale it to a unit box $B_1$. Using an smooth approximation of $U_{\text{cou}}$ (see $U_{\text{GS}}$ in (2.5)), the Coulomb potential is split into two integrals, i.e. the long-range regular integral and the short-range singular integral. To be precise,

$$\Phi(x) \approx \int_{B_1} U_{\text{cou}}(x - y) \rho(y) dy = \int_{B_2} U_{\text{cou}}(y) \rho(x - y) dy = \int_{B_2} U_{\text{GS}}(y) \rho(x - y) dy + \int_{B_2 \setminus B_3} (U_{\text{cou}}(y) - U_{\text{GS}}(y)) \rho(x - y) dy + I_\delta \quad (2.1)$$

where

$$I_\delta = \int_{B_2 \setminus B_3} (U_{\text{cou}}(y) - U_{\text{GS}}(y)) \rho(x - y) dy \quad (2.2)$$

The remainder integral $I_\delta$ is given explicitly as

$$I_\delta = \int_{B_2 \setminus B_3} (U_{\text{cou}}(y) - U_{\text{GS}}(y)) \rho(x - y) dy \quad (2.3)$$

4
where $B_δ := \{x| |x| \leq δ\}$ is a very small ball centered at the origin and

$$U_{GS}(y) = U_{GS}(|y|) := \sum_{q=0}^{Q} w_q e^{-\frac{\tau_q}{2} |y|^2}, \quad Q \in \mathbb{N}^+.$$  \hfill (2.5)

Here, $U_{GS}$ is an very accurate approximation of $U_{cou}$ within the interval $[δ, 2]$, i.e.

$$\|U_{cou}(r) - U_{GS}(r)\|_{L^\infty([δ, 2])} \leq \varepsilon_0, \quad \varepsilon_0 \in [10^{-16}, 10^{-14}].$$  \hfill (2.6)

It can be proved that $I_δ$ is negligible and we omitted it in computation.

To compute the regular integral $I_1$, plugging $U_{GS}$ (2.5), we have

$$I_1(x) = \sum_{q=0}^{Q} w_q \int_{B_2} e^{-\frac{\tau_q}{2} |y|^2} \rho(x - y)dy, \quad x \in B_1.$$  \hfill (2.7)

The density $\rho(x - y), x \in B_1, y \in B_2$ is well approximated by Fourier series as follows

$$\rho(z) \approx \sum_{k} \hat{\rho}_k \prod_{j=1}^{d} e^{\frac{2\pi i k_j}{z^{(j)} - a_j}}, \quad z = (z^{(1)}, \ldots, z^{(d)}) \in B_3.$$  \hfill (2.8)

Careful calculations leads to

$$I_1(x) = \sum_{k} \hat{\rho}_k \left( \sum_{q=0}^{Q} w_q G^q_k \right) \prod_{j=1}^{d} e^{\frac{2\pi i k_j}{z^{(j)} - a_j}},$$  \hfill (2.9)

where

$$G^q_k = \prod_{j=1}^{d} \int_{-2}^{2} e^{-\frac{\tau_q}{2} |y^{(j)}|^2} e^{\frac{2\pi i a_j}{z^{(j)} - a_j}} dy^{(j)},$$  \hfill (2.10)

can be pre-computed once for all if the computation grid remains unchanged.

For the near-field correction integral $I_2$, the density function $\rho_x(y) := \rho(x - y)$ is approximated by a low-order Taylor expansion within $B_δ$ as follows

$$\rho_x(y) \approx \rho_x(0) + \sum_{j=1}^{d} \frac{\partial \rho_x(0)}{\partial y_j} y_j + \frac{1}{2} \sum_{j,k=1}^{d} \frac{\partial^2 \rho_x(0)}{\partial y_j \partial y_k} y_j y_k + \frac{1}{6} \sum_{j,k,\ell=1}^{d} \frac{\partial^3 \rho_x(0)}{\partial y_j \partial y_k \partial y_\ell} y_j y_k y_\ell.$$  \hfill (2.11)

We then integrate it in spherical/polar coordinates. The computation boils down to a multiplication of the Laplacian $\Delta \rho$ since the contributions of the odd derivatives in (2.11) and off-diagonal components of the Hessian vanish. Derivatives of $\rho$ are computed via its Fourier series. For more details, we refer the reader to [5, 22].

The GauSum method achieves a spectral accuracy and is essentially as efficient as FFT algorithms within $O(N \log N)$ arithmetic operations. The algorithm has been implemented for DDI [22] and applied in the studies of fractional Schrödinger equations [5].

3. Dynamics properties and the numerical method

In this section, we first present analogous dynamical laws for some commonly used quantities in classical rotating CGPE. Then, we extend the rotating Lagrangian coordinate transform proposed for the classical GPE in [13]. In the rotating Lagrangian coordinates, the rotation term vanishes, instead the potential becomes time-dependent. For the new equation, we shall propose a time-splitting Fourier spectral method incorporated with the GauSum solver to compute the dynamics.
3.1. Dynamical properties

Here we study the dynamical properties of the mass, energy, angular momentum expectation and center of mass. The dynamical laws can be used as benchmarks to test the numerical methods and are briefly listed here. For details, one can prove in an analogous way to the one component \[9\] or two-component without DDI \[3\].

**Mass and energy.** The CGPE (1.1)-(1.2) conserves the mass (1.8) and energy (1.9), i.e.

$$N_1(t) = N_1(t = 0), \quad N_2(t) = N_2(t = 0), \quad \mathcal{N}(t) := (N_1 + N_2)(t) = \mathcal{N}(t = 0), \quad \mathcal{E}(t) = \mathcal{E}(t = 0) \quad (3.1)$$

**Angular momentum expectation.** The angular momentum expectation for each component and the total angular momentum are defined respectively as

$$\langle L_z \rangle_j(t) = \int_{\mathbb{R}^d} \psi_j^*(x,t) L_z \psi_j(x,t) \, dx, \quad j = 1, 2, \quad \langle L_z \rangle(t) = \langle L_z \rangle_1(t) + \langle L_z \rangle_2(t), \quad t \geq 0. \quad (3.2)$$

**Lemma 3.1.** If \(V_j(x)\) reads as the harmonic potential, we have for \(j = 1, 2\) and \(k_j = 3 - j\)

$$\frac{d}{dt} \langle L_z \rangle_j(t) = w_j^2 \int_{\mathbb{R}^d} xy |\psi_j|^2 \, dx + \int_{\mathbb{R}^d} |\psi_j|^2 (y \partial_x - x \partial_y) \left( \beta_{j,k_j} |\psi_{k_j}|^2 + \sum_{k=1}^2 \lambda_{j,k} \Phi_k(x,t) \right) \, dx, \quad (3.3)$$

Moreover, if additionally \(\beta_{12} = \beta_{21}\), we have

$$\frac{d}{dt} \langle L_z \rangle(t) = \sum_{j=1}^2 w_j^2 \int_{\mathbb{R}^d} xy |\psi_j|^2 \, dx + \sum_{j,k=1}^2 \lambda_{j,k} \int_{\mathbb{R}^d} |\psi_j|^2 (y \partial_x - x \partial_y) \Phi_k(x,t) \, dx. \quad (3.4)$$

Here \(w_j^2 = \gamma_{x,j}^2 - \gamma_{y,j}^2\). This implies that the total angular momentum expectation \(\langle L_z \rangle(t)\) is conserved, i.e.

$$\langle L_z \rangle(t) = \langle L_z \rangle(0), \quad t \geq 0, \quad (3.5)$$

if \(\gamma_{x,j} = \gamma_{y,j}\) and one of the following condition holds: (i). \(\lambda_{11} = \lambda_{12} = \lambda_{21} = \lambda_{22} = 0\). (ii). \(\lambda_{12} = \lambda_{21}\) and the dipole axises parallel to the z-axis, i.e. \(\mathbf{n}_1 = \mathbf{n}_2 = (0, 0, 1)^T\). Moreover, the angular momentum expectation for each component is also conserved, i.e.

$$\langle L_z \rangle_j(t) = \langle L_z \rangle_j(0), \quad j = 1, 2, \quad t \geq 0, \quad (3.6)$$

if additionally provide \(\lambda_{12} = \lambda_{21} = \beta_{12} = \beta_{21} = 0\).

**Proof 3.1.** Let us take a close look at the DDI term in (3.4). Using the Plancherel’s formula, we have

$$\langle \rho_j, (y \partial_x - x \partial_y) \Phi_k \rangle := \int_{\mathbb{R}^d} |\psi_j|^2 (-\partial_y \Phi_k) \, dx = \frac{1}{(2\pi)^d} \langle \hat{\rho}_j, -\partial_y \hat{\Phi}_k \rangle \quad (3.7)$$

$$= \frac{1}{(2\pi)^d} \langle \hat{\rho}_j, -\partial_k \hat{U}_{\text{dip}} \hat{\rho}_k \rangle \quad (3.8)$$

where the Fourier transform is defined as \(\hat{f}(\xi) = \int_{\mathbb{R}^d} f(x) e^{-i\xi \cdot x} \, dx\),

$$\hat{U}_{\text{dip}}(\xi) = \begin{cases} 
-1 + \frac{3(\mathbf{n} \cdot \xi)^2}{2|\xi|^d} + \frac{6(n_z \xi_z)^2}{d|\xi|^d}, & d = 3, \\
2(\mathbf{n} \cdot \xi)^2(n_1^2 - n_z^2)|\xi|^{d-2}, & d = 2,
\end{cases} \quad (3.9)$$
and \( \theta, \theta_2 \) are the azimuth angle in physical/Fourier space respectively. For \( \mathbf{n} = (0,0,1)^T \), it is easy to see that \( \hat{U}_{\text{dip}}(\xi) \) is cylindrical/polar symmetric in 3D and 2D respectively, and we have

\[
\langle \rho_j, -\partial_\theta \Phi_k \rangle = \frac{1}{(2\pi)^d} \langle \hat{\rho}_j, -\partial_\theta (\hat{U}_{\text{dip}} \hat{\rho}_k) \rangle = \frac{1}{(2\pi)^d} \langle \hat{U}_{\text{dip}} \hat{\rho}_j, -\partial_\theta \hat{\rho}_k \rangle
\]

(3.10)

\[
= \langle \Phi_j, -\partial_\theta \rho_k \rangle = \langle \partial_\theta \Phi_j, \rho_k \rangle
\]

(3.11)

\[
= -\langle \rho_k, -\partial_\theta \Phi_j \rangle.
\]

(3.12)

The proof is then completed due to the above anti-symmetric property in the index \((j,k)\).

**Center of mass.** The (total) center of mass is defined as

\[
x_{c,j}(t) = \int \mathbb{R}^d x |\psi_j(x,t)|^2 dx, \quad j = 1, 2, \quad x_c(t) = x_{c,1}(t) + x_{c,2}(t), \quad t \geq 0.
\]

(3.13)

**Lemma 3.2.** If \( V_j(x) \) reads as the harmonic potential, we have for \( j = 1, 2 \) and \( k = 3 - j \)

\[
x_{c,j} = 2 \Omega J_d x_{c,j} + (\Lambda_1 + \Omega^2 J_d^2) x_{c,j} = \int \mathbb{R}^d \left( \beta_j k_j |\psi_j|^2 + \lambda_{j,k} \Phi_j \right) \nabla |\psi_j|^2 dx,
\]

(3.14)

\[
x_{c,j} = \int \mathbb{R}^d x^0 \nabla |\psi_j|^2 dx,
\]

(3.15)

where,

\[
J_d = \begin{cases} 
(0, 1, -1) & , \quad d = 2, \\
(0, 0, 0) & , \quad d = 3.
\end{cases}
\]

(3.16)

Moreover, if \( V_1(x) = V_2(x), \beta_{12} = \beta_{21} \) and \( \lambda_{12} = \lambda_{21} \), we have

\[
x_{c} - 2 \Omega J_d x_{c} + (\Lambda_{d,1} + \Omega^2 J_d^2) x_{c} = 0,
\]

(3.17)

\[
x_{c} = x_{c,1} + x_{c,2}, \quad \dot{x}_{c} = \dot{x}_{c,1} + \dot{x}_{c,2}.
\]

(3.18)

**An analytical solution under special initial data.** An interesting application of the dynamical law [3.17] for the total center of mass is that under some circumstances we can construct an analytical solution to the CGPE. Precisely speaking, suppose the initial condition \( \psi_0 \) in (1.2) is chosen as

\[
\psi_0(x) = \phi_0^*(x - x_0), \quad x \in \mathbb{R}^d,
\]

(3.19)

where \( x_0 \in \mathbb{R}^d \) is a given point and \( \phi_j^* \) is a stationary state of the CGPE, i.e.

\[
\mu_j^* \phi_j^* = \left[ -\frac{1}{2} \nabla^2 + V_j(x) - \Omega L_z + \sum_{k=1}^2 (\beta_{jk} |\phi_k|^2 + \lambda_{jk} \Omega_{dip} + |\phi_k^*|^2) \right] \phi_j^*,
\]

(3.20)

\[
\int \mathbb{R}^d |\phi_j^*|^2 dx = 1, \quad j = 1, 2.
\]

(3.21)

where \( \mu_j^* \in \mathbb{R} \) are the chemical potentials. With this initial value, and suppose \( V_1(x) = V_2(x) \), the exact solution of the CGPE with harmonic potential can be constructed as

\[
\psi_{j}(x,t) = \phi_j^*(x - x_c(t)) e^{-i \int_{\mathbb{R}}^t e^{i w(x,s)} ds}, \quad x \in \mathbb{R}^d, \quad t \geq 0
\]

(3.22)

where \( w(x,t) \) is linear in \( x \), i.e.

\[
w(x,t) = c_1(t) \cdot x + c_2(t), \quad x \in \mathbb{R}^d, \quad t \geq 0,
\]

(3.23)

with some functions \( c_1(t), c_2(t) \), and \( x(t) \) satisfying the ODE (3.17) with initial condition

\[
x_0^0 = x_0, \quad \dot{x}_c^0 = -\Omega J_d x^0.
\]

(3.24)
3.2. Numerical method

3.2.1. CGPE under rotating Lagrangian coordinates

In this section, we first introduce a rotating Lagrangian coordinate and then reformulate the CGPE \( \tilde{\psi}_d(t) \) in the new coordinate system. For any time \( t \geq 0 \), let \( A_d(t) \) be an orthogonal rotational matrix in \( \mathbb{R}^d \) defined as [13, 59]

\[
A_d(t) = \begin{pmatrix}
\cos(\Omega(t)) & \sin(\Omega(t)) \\
-\sin(\Omega(t)) & \cos(\Omega(t))
\end{pmatrix}, \quad \text{if } d = 2,
\]

\[
A_d(t) = \begin{pmatrix}
A_2(t) & 0 \\
0 & 1
\end{pmatrix}, \quad \text{if } d = 3.
\]

(3.25)

It is easy to verify that \( A_d^{-1}(t) = A_d^T(t) \) for any \( t \geq 0 \) and \( A(0) = I \) with \( I \) the identity matrix. For all \( t \geq 0 \), the rotating Lagrangian coordinates \( \tilde{x} \) is defined as

\[
\tilde{x} = A_d^{-1}(t)x = A_d^T(t)x \quad \iff \quad x = A_d(t)\tilde{x}, \quad x \in \mathbb{R}^d, \quad t \geq 0.
\]

(3.26)

Denotes the wave function in the new coordinates as \( \psi_j(\tilde{x}, t) \):

\[
\psi_j(\tilde{x}, t) := \tilde{\psi}_j(\tilde{x}, t) = \psi_j(A_d(t)\tilde{x}, t), \quad j = 1, 2 \quad \tilde{x} \in \mathbb{R}^d, \quad t \geq 0.
\]

(3.26)

By simple calculation, we have

\[
i\partial_t \phi_j(\tilde{x}, t) = i\partial_t \psi_j(x, t) + i\nabla_x \psi_j(x, t) \cdot \left( A_d(t)\mathbf{\tilde{x}} \right) = i\partial_t \psi_j(x, t) + \Omega L_z \psi_j(x, t),
\]

\[
\nabla_x \psi_j(\tilde{x}, t) = A_d^{-1}(t)\nabla_x \psi_j(x, t), \quad \nabla^2_x \phi_j(\tilde{x}, t) = \nabla^2_x \psi_j(x, t), \quad x \in \mathbb{R}^d, \quad t \geq 0.
\]

Substituting the above derivatives into \((1.1) - (1.2)\) leads to the following \( d \)-dimensional CGPE in the rotating Lagrangian coordinates \( \tilde{x} \), for \( j = 1, 2 \)

\[
i\partial_t \phi_j(\tilde{x}, t) = -\frac{1}{2} \nabla^2 + W_j(\tilde{x}, t) + \sum_{k=1}^2 \left( \beta_{jk} |\phi_k|^2 + \lambda_{jk} \tilde{\Phi}_k \right) \phi_j, \quad \tilde{x} \in \mathbb{R}^d, \quad t > 0,
\]

(3.28)

\[
\tilde{\phi}_j(\tilde{x}, t) = \tilde{U}_{\text{dd}} \ast |\phi_k|^2, \quad \phi_j(\tilde{x}, 0) := \tilde{\phi}_j(\tilde{x}) = \tilde{\phi}_j(\tilde{x}), \quad \tilde{x} \in \mathbb{R}^d.
\]

(3.29)

Here, \( W_j(\tilde{x}, t) = V_j(A_d(t)\tilde{x}) \) \( (j = 1, 2) \) and the DDI kernel \( \tilde{U}_{\text{dd}}(\tilde{x}, t) \) reads as

\[
\tilde{U}_{\text{dd}}(\tilde{x}, t) = \begin{cases}
-\delta(\tilde{x}) - 3 \partial_m(t)m(t) \left( \frac{4\pi}{|\tilde{x}|} \right), & d = 3, \\
-\frac{1}{2} \left( \partial_{m_+}(t)m_+ - m_3^2 \right) \left( \frac{1}{2\pi |\tilde{x}|} \right), & d = 2,
\end{cases}
\]

(3.30)

with \( m(t) \in \mathbb{R}^3 \) defined as \( m(t) = A_d^{-1}(t)m = (m_1(t), m_2(t), m_3(t))^T \) and \( m_3(t) := (m_1(t), m_2(t))^T \).

In rotating Lagrangian coordinates, the energy associated with the CGPE \((3.28) - (3.29)\) is defined as

\[
\tilde{\mathcal{E}}(t) = \sum_{j=1}^2 \int_{\mathbb{R}^d} \left[ |\nabla \phi_j|^2 + W_j(\tilde{x}, t)|\phi_j|^2 + \sum_{k=1}^2 \left( \frac{\beta_{jk}}{2} |\phi_k|^2 + \frac{\lambda_{jk}}{2} \tilde{\Phi}_k \right) |\phi_j|^2 \right] d\tilde{x}
\]

- \sum_{j=1}^2 \int_{\mathbb{R}^d} \int_0^t \left[ \partial_\tau W_j(\tilde{x}, \tau)d\tau + \sum_{k=1}^2 \frac{\lambda_{jk}}{2} (\partial_{\tau \tilde{U}_{\text{dd}}}) |\phi_k|^2 \right] |\phi_j|^2 d\tilde{x}
\]

=: \tilde{\mathcal{E}}_{\text{kin}}(t) + \tilde{\mathcal{E}}_{\text{pot}}(t) + \tilde{\mathcal{E}}_{\text{short}}(t) + \tilde{\mathcal{E}}_{\text{dd}}(t) + \tilde{\mathcal{E}}_{\text{extra}}(t),
\]

(3.31)

where

\[
\tilde{\mathcal{E}}_{\text{kin}}(t) = \frac{1}{2} \int_{\mathbb{R}^d} \left[ |\nabla \phi_1|^2 + |\nabla \phi_2|^2 \right] d\tilde{x}, \quad \tilde{\mathcal{E}}_{\text{pot}}(t) = \int_{\mathbb{R}^d} \left[ W_1(\tilde{x}, t)|\phi_1|^2 + W_2(\tilde{x}, t)|\phi_2|^2 \right] d\tilde{x},
\]

\[
\tilde{\mathcal{E}}_{\text{short}}(t) = \frac{1}{2} \sum_{j,k=1}^2 \beta_{jk} \int_{\mathbb{R}^d} |\phi_j|^2 |\phi_k|^2 d\tilde{x}, \quad \tilde{\mathcal{E}}_{\text{dd}}(t) = \frac{1}{2} \sum_{j,k=1}^2 \lambda_{jk} \int_{\mathbb{R}^d} \Phi_k |\phi_j|^2 d\tilde{x},
\]

\[
\tilde{\mathcal{E}}_{\text{extra}}(t) = -\frac{1}{2} \sum_{j=1}^2 \int_{\mathbb{R}^d} \int_0^t \left[ \partial_\tau W_j(\tilde{x}, \tau)d\tau + \sum_{k=1}^2 \frac{\lambda_{jk}}{2} (\partial_{\tau \tilde{U}_{\text{dd}}}) |\phi_k|^2 \right] |\phi_j|^2 d\tilde{x}.
\]
and
\[ \partial_t \tilde{U}_{\text{dip}}(\tilde{x}, t) = -3 \begin{cases} 2 \partial_m(t)m(t) \left( \frac{1}{1 + |\mathbf{x}|} \right), & d = 3, \\ \partial_m(t)m(t) \left( \frac{1}{2 + |\mathbf{x}|} \right), & d = 2, \end{cases} \] (3.32)

**Remark 3.1.** If \( V_j(\mathbf{x}) \) is a harmonic potential as defined in (3.3), then \( W_j(\tilde{x}, t) \) has the form
\[ W_j(\tilde{x}, t) = \frac{w^+}{4}(\tilde{x}^2 + \tilde{y}^2) + \frac{w^-}{4}[(\tilde{x}^2 - \tilde{y}^2) \cos(2\Omega t) + 2\tilde{x}\tilde{y} \sin(2\Omega t)] + \begin{cases} 0, & d = 2, \\ \frac{1}{2}\gamma_{z, j}^2 \tilde{z}^2, & d = 3, \end{cases} \] (3.33)
where \( w^+ = \gamma_{x, j}^2 + \gamma_{y, j}^2 \) and \( w^- = \gamma_{x, j}^2 - \gamma_{y, j}^2 \). Therefore, when the external potential is either box-potential or harmonic potential which are radially symmetric in two dimensions (2D) or cylindrically symmetric in three dimensions (3D), i.e. \( \gamma_{x, j} = \gamma_{y, j} := \gamma_{r, j} \), the potential \( W_j(\tilde{x}, t) \) becomes time-independent.

Compared to (1.11), (1.2), the rotating term now vanishes in the new CGPE (3.28)-(3.29). Instead, the trapping potential and DDI kernel now become time-dependent. The absence of rotating term now allows us to develop an efficient method to solve (3.28)-(3.29).

### 3.2.2. Time splitting Fourier pseudospectral method
Here we shall consider the new equation (3.28)-(3.29). Due to the trapping potential, the wave functions decay exponentially at the far field. Therefore, in practical computation, it suffices to truncate the problem into a large enough bounded computational domain \( \mathcal{D} = [a, b] \times [c, e] \times [f, g] \) if \( d = 3 \), or \( \mathcal{D} = [a, b] \times [c, e] \) if \( d = 2 \). From \( t = t_n \) to \( t = t_{n+1} = t_n + \Delta t \), the CGPE will be solved in two steps, i.e. for \( j = 1, 2 \) one first solves
\[ i\partial_t \phi_j(\tilde{x}, t) = -\frac{1}{2} \nabla^2 \phi_j(\tilde{x}, t), \quad \tilde{x} \in \mathcal{D}, \quad t_n \leq t \leq t_{n+1}, \] (3.34)
with periodic boundary conditions on the boundary \( \partial\mathcal{D} \) for a time step of length \( \Delta t \), then solves
\[ i\partial_j \tilde{\Phi}_k(\tilde{x}, t) = \left[ \mathcal{W}_j(\tilde{x}, t) + \sum_{k=1}^2 (\beta_{jk} |\phi_k|^2 + \lambda_{jk} \tilde{\Phi}_k) \right] \phi_j, \quad \tilde{x} \in \mathcal{D}, \quad t_n \leq t \leq t_{n+1}, \] (3.35)
\[ \tilde{\Phi}_k(\tilde{x}, t) = (\tilde{U}_{\text{dip}} \ast \tilde{\rho}_k)(\tilde{x}, t), \quad k = 1, 2, \quad \tilde{x} \in \mathcal{D}, \quad t_n \leq t \leq t_{n+1}, \] (3.36)
for the same time step. Here, \( \tilde{\rho}_k(\tilde{x}, t) = |\phi_k(\tilde{x}, t)|^2 \) if \( \tilde{x} \in \mathcal{D} \) and \( \tilde{\rho}_k(\tilde{x}, t) = 0 \) otherwise. The linear subproblem (3.34) will be discretised in space by the Fourier pseudospectral method and integrated in time exactly in the phase space, while the nonlinear subproblem (3.35)-(3.36) preserves the density point-wisely, i.e. \( |\phi_j(\tilde{x}, t)|^2 \equiv |\phi_j(\tilde{x}, t_n)|^2 = |\phi^n_j(\tilde{x})|^2 \), and it can be integrated exactly as
\[ \phi_j(\tilde{x}, t) = \exp \left\{ -i \int_{t_n}^t P_j(\tilde{x}, t, u) + \sum_{k=1}^2 (\beta_{jk} |\phi_k|^2(t - u) + \lambda_{jk} \varphi_k(\tilde{x}, u)) \right\}, \] (3.37)
\[ \varphi_k(\tilde{x}, t) = \int_{\mathbb{R}^d} \tilde{K}(\tilde{x}, \tilde{y}, u) \tilde{\rho}_k(\tilde{y}, u)n(\tilde{y}) d\tilde{y}, \quad \tilde{x} \in \mathcal{D}, \quad t_n \leq t \leq t_{n+1}, \] (3.38)
where the time-dependent kernel \( \tilde{K}(\tilde{x}, t) \) has the form
\[ \tilde{K}(\tilde{x}, t) = \int_{t_n}^t \tilde{U}_{\text{dip}}(\tilde{x}, \tau) d\tau = \begin{cases} -\delta(\tilde{x})(t - t_n) - 3\tilde{L}_3(t)(\frac{1}{4|x|}), & 3\text{D DDI}, \\ -\frac{3}{2}\tilde{L}_2(t)(\frac{1}{2|x|}), & 2\text{D DDI}. \end{cases} \] (3.39)
Here, the differential operator \( \tilde{L}_3(t) = \int_{t_n}^t \partial_{m(\tau)m(\tau)}d\tau \) and \( \tilde{L}_2(t) = \int_{t_n}^t \partial_{m(\tau)m(\tau)}d\tau - m_3^2\nabla^2 d\tau \) actually can be integrated analytically and has explicit expressions, one can refer to section 4.1 in [13] for details. The GauSum solver is then applied to evaluate the nonlocal potential \( \varphi(\tilde{x}, t) \) (3.38). In addition,
\[ P_j(\tilde{x}, t) = \int_{t_n}^t \mathcal{W}_j(\tilde{x}, \tau) d\tau. \] (3.40)
Remark 3.2. If $V_j(x)$ ($j = 1, 2$) is a harmonic potential as defined in \(1.3\), i.e. $W_j$ reads as \(3.33\), then the integral in \(3.40\) can be evaluated analytically, i.e.

\[
\int_{t_n}^{t} W_j(\tilde{x}, \tau) d\tau = \frac{w_j^+ (\tilde{x}^2 + \tilde{y}^2)}{4} (t - t_n) + \frac{w_j^-}{8\Omega} \left((\tilde{x}^2 - \tilde{y}^2) (\sin(2\Omega \tau) - \sin(2\Omega t_n)) \right) - 2\tilde{y} \left(\cos(2\Omega \tau) - \cos(2\Omega t_n)\right) + 0, \quad t_n \leq \tau \leq t, \quad d = 2,
\]

\[
\int_{t_n}^{t} W_j(\tilde{x}, \tau) d\tau = \frac{\tilde{y}^2}{1/2} \tilde{z}^2 (t - t_n), \quad d = 3,
\]

\[
(3.41)
\]

\[
(3.42)
\]

For a general potential $V_j(x)$, if the integral in \(3.40\) cannot be found analytically, numerical quadratures such as Trapezoidal rule or Simpson’s rule can be used to approximate it [11, 13].

To simplify the presentation, we will only present the scheme for the 3D case. As for the 2D case, one can modify the algorithm straightforwardly. Let $L, M, N$ be even positive integers, choose $h_x = \frac{L}{L}, h_y = \frac{d-y}{M}$ and $h_z = \frac{d-z}{N}$ as the spatial mesh sizes in $x$, $y$, and $z$ directions, respectively. Define the index and grid points sets as

\[
T_{LMN} = \{(l, k, m) | 0 \leq l \leq L, 0 \leq k \leq M, 0 \leq m \leq N\},
\]

\[
\tilde{T}_{LMN} = \{(p, q, r) | -\frac{L}{2} \leq p \leq \frac{L}{2} - 1, -\frac{M}{2} \leq q \leq \frac{M}{2} - 1, -\frac{N}{2} \leq r \leq \frac{N}{2} - 1\},
\]

\[
G_{\tilde{T}_{LMN}} = \{(\tilde{x}, \tilde{y}, \tilde{z}) := (l h_x + a, k h_y + c, m h_z + e), (l, k, m) \in T_{LMN}\}.
\]

Define the functions

\[
W_{pq}(\tilde{x}, \tilde{y}, \tilde{z}) = e^{i\mu^p_x (\tilde{x} - a)} e^{i\mu^p_y (\tilde{y} - b)} e^{i\mu^p_z (\tilde{z} - c)}, \quad (p, q, r) \in \tilde{T}_{LMN},
\]

with

\[
\mu^p_x = \frac{2p \pi}{L}, \quad \mu^p_y = \frac{2q \pi}{M}, \quad \mu^p_z = \frac{2r \pi}{N}, \quad (p, q, r) \in \tilde{T}_{LMN}.
\]

Let $f_{j,km}^n$ ($j = 1, 2$, $f_j = \phi_j, \varphi_j$, or $P_j$) be the numerical approximation of $f_{j}(\tilde{x}, \tilde{y}, \tilde{z}, t_n)$ for $(l, k, m) \in T_{LMN}$, $n \geq 0$ and denote $\phi_j^n$ as the solution vector at time $t = t_n$ with components \(\phi_j^{n, lkm}\), $(l, k, m) \in T_{LMN}$). Taking the initial data as \(\phi_j^{0, lkm} = \phi_j^{0}(\tilde{x}, \tilde{y}, \tilde{z}, t_0)\) for $(l, k, m) \in T_{LMN}$, a second-order Time Splitting Fourier Pseudospectral (TSFP) method to solve the CGPE \(3.28\)–\(3.29\) reads as follows:

\[
\phi_j^{(1), lkm} = \sum_{p=-L/2}^{L/2-1} \sum_{q=-M/2}^{M/2-1} \sum_{r=-N/2}^{N/2-1} e^{-i\frac{\pi}{L} [\omega_p^x + (\omega_q^y)^2 + (\omega_r^z)^2]} (\phi_j^{n, lkm} W_{pq}(\tilde{x}, \tilde{y}, \tilde{z})), \quad (3.43)
\]

\[
\phi_j^{(2), lkm} = \phi_j^{(1), lkm} \exp \left\{ -i \Delta t \sum_{s=1,2} \left( \beta_{js} \phi_j^{(1), lkm} + \lambda_{js} \varphi_{s, lkm}^{n+1} \right) + P_j^{n+1} \right\} \right\}, \quad (3.44)
\]

\[
\phi_j^{n+1} = \sum_{p=-L/2}^{L/2-1} \sum_{q=-M/2}^{M/2-1} \sum_{r=-N/2}^{N/2-1} e^{-i\frac{\pi}{L} [\omega_p^x + (\omega_q^y)^2 + (\omega_r^z)^2]} (\phi_j^{(2), lkm} W_{pq}(\tilde{x}, \tilde{y}, \tilde{z})), \quad (3.45)
\]

Here, $(\phi_j^{(1), lkm})_pq$ and $(\phi_j^{(2), lkm})_pq$ are the discrete Fourier transform coefficients of the vectors $\phi_j^n$ and $\phi_j^2$, respectively. We refer this method as TS2-GAUSUM. This scheme is explicit, efficient, simple to implement, unconditional stable and can be extended to high-order time-splitting schemes easily.

4. Numerical results

In this section, we first test the accuracy of the TS2-GAUSUM method for computing the dynamics of rotating two-component dipolar BEC. Then, we apply our method to investigate some interesting phenomena, such as the dynamics of dipolar BEC with tunable (time-dependent) dipole axis, collapse properties of a dipolar BEC.
4.1. Test of the accuracy

Here, we first test the spatial and temporal accuracy of our method in both 2D and 3D. To demonstrate the results, we first define the following error function

$$e^{h,\Delta t}(t) =: \|\Psi(x, t_n) - \Psi_h^\beta(t_n, t_n)\|_2 = \sqrt{\sum_{j=1}^{2} \|\psi_j(x, t_n) - \psi_j^h(t_n, t_n)\|_2^2},$$  \hspace{1cm} (4.46)$$

where $\|\cdot\|_2$ denotes the discrete $l^2$ norm, $\psi_j^h(t_n, t_n)$ is the numerical approximation of $\psi_j(x, t_n)$ obtained by the TS2-GauSum method (3.43)-(3.45) with time step $\Delta t$ and mesh size $h = h^0(v = \bar{x}, \bar{y}$ in 2D and $v = \bar{x}, \bar{y}, \bar{z}$ in 3D). The dipole axis $n$ and interaction parameters are chosen as

$$n = (1, 0, 0)^T, \quad \begin{pmatrix} \beta_1 \\ \beta_2 \\ \beta_3 \end{pmatrix} = \begin{pmatrix} \beta_1 \\ \beta_2 \\ \beta_3 \end{pmatrix}, \quad \begin{pmatrix} \lambda_1 \\ \lambda_2 \end{pmatrix} = \begin{pmatrix} \lambda_1 \\ \lambda_2 \end{pmatrix}. \hspace{1cm} (4.47)$$

Moreover, we take the computational domain $D = [-12, 12]^2(2D)/[-8, 8]^3(3D)$ and potential $V_1(x) = \frac{|x|^2}{2}$. The potential $V_2(x)$ and initial data $\psi_j^0(x)$ are chosen respectively as

$$V_2(x) = \begin{cases} (x^2 + y^2)/2, & j = 1, 2, \\ (x^2 + 1.2y^2 + z^2)/2, & j = 3, \end{cases} \quad \psi_j^0(x) = \begin{cases} \sqrt{\frac{2}{\pi}} e^{-\frac{\beta_1}{2} x^2 + \frac{\beta_2}{2} y^2}, & d = 2, \\ \sqrt{\frac{2}{\pi}} e^{-\frac{\beta_1}{2} x^2 - \frac{\beta_2}{2} y^2 + \beta_3 z^2}, & d = 3, \end{cases} \hspace{1cm} (4.48)$$

For comparisons, the “exact” solution $\Psi(x, t)$ is obtained numerically via the TS2-GauSum method on $D$ with a very small mesh size $h = h^0 = \frac{1}{16}$ and time step $\Delta t = \Delta t_0 = 0.0001$. Table 4.1 lists the spatial errors $e^{h,\Delta t}$ and temporal errors $e^{h,\Delta t}$ at time $t = 0.4$ for the 2D CGPE with $\Omega = 0.4$ and different $\beta$, while Tab. 4.2 lists those at time $t = 0.1$ for the 3D case with $\Omega = 0.2$ and different $\beta$. From Tabs. 4.1-4.2, we can conclude that the TS2-GauSum method is spectrally accurate in space and second order accurate in time.

| $e^{h,\Delta t}$ | $h = 1$ | $h/2$ | $h/4$ | $h/8$ |
|-----------------|---------|-------|-------|-------|
| $\beta = 2$    | 1.0863E-01 | 2.9827E-03 | 2.8843E-07 | 1.0490E-11 |
| $\beta = 10$   | 3.8018E-01 | 4.2192E-02 | 7.4791E-05 | 1.4662E-11 |

| $e^{h,\Delta t}$ | $\Delta t = 0.01$ | $\Delta t/2$ | $\Delta t/4$ | $\Delta t/8$ |
|-----------------|------------------|----------------|----------------|----------------|
| $\beta = 2$    | 2.4167E-05 | 6.0376E-06 | 1.5074E-06 | 3.7504E-07 |
| $\beta = 10$   | 2.2051E-04 | 5.5049E-05 | 1.3742E-05 | 3.4187E-06 |

4.2. Dynamics of the center of mass

In this subsection, we study the dynamics of the center of mass by directly simulating the CGPE (3.28)-(3.29) via the TS2-GauSum method (3.43)-(3.45). To this end, we take $d = 2$, dipole axis $n = (1, 0, 0)^T$ and initial data (1.2)

$$\psi_j^0(x) = \phi(x - x_0), \quad \psi_j^0(x) = \phi(x + x_0), \quad \text{with} \quad \phi(x) = \frac{(x + iy)}{\sqrt{2\pi}} e^{-\frac{x^2 + y^2}{2}}, \quad x_0 = (1, 1)^T. \hspace{1cm} (4.49)$$

The computational domain, mesh size and time step are respectively take as $D = [-16, 16]^2$, $h_x = h_y = \frac{1}{8}$ and $\Delta t = 0.001$. The trapping potentials are chosen as the harmonic ones (1.3) and the following 6 cases are studied ($j = 1, 2, k_j = 3 - j$)
Table 4.2: Spatial and temporal discretization errors at time $t = 0.1$ for the 3D CGPE with $\Omega = 0.2$ and different $\beta$.

| $e_{\varphi}^{h, \Delta t h}$ | $h = 1$ | $h/2$ | $h/4$ | $h/8$ |
|-------------------------------|---------|-------|-------|-------|
| $\beta = 2$                  | 1.51E-02 | 1.82E-04 | 1.92E-08 | 6.60E-13 |
| $\beta = 10$                 | 2.60E-02 | 9.25E-04 | 8.70E-07 | 7.25E-13 |

- Case 1: $\Omega = 0.5$, $\beta_{11} = \frac{\beta_2}{2} = 50$, $\lambda_{jj} = \frac{\beta_i}{10}$, $\beta_{jk} = \frac{2\lambda_{jk}}{5} = 2$, $\gamma_{x,j} = \gamma_{y,j} = 1$.
- Case 2: $\Omega = 0.5$, $\beta_{jj} = 10\lambda_{jj} = 50$, $\beta_{jk} = \frac{2\lambda_{jk}}{5} = 2$, $\gamma_{x,1} = \gamma_{y,2} = 1.1$, $\gamma_{y,1} = \gamma_{x,2} = 1$.
- Case 3: $\Omega = 0.5$, $\beta_{jj} = 10\lambda_{jj} = 50$, $\beta_{jk} = \frac{2\lambda_{jk}}{5} = 2$, $\gamma_{x,1} = \gamma_{y,1} = 1$, $\gamma_{x,2} = \gamma_{y,2} = 1.2$.
- Case 4-6: same parameters as in Case 1-3, except only change as $\Omega = 1$, $\Omega = \pi$ and $\Omega = \pi$, respectively.

Figures 4.1-4.2 show the dynamics of the center of mass $x_{c,j}(t)$ ($j = 1, 2$) and its trajectory in the Cartesian coordinates for Case 1-6. From Figs. 4.1-4.2 and additional results not shown here for brevity, we can conclude that: (i) When $\Omega < \min\{\gamma_{x,j}, \gamma_{y,j}\}$, then the center of mass of the $j$-th component $x_{c,j}$ always moves within a bounded domain (cf. Fig. 4.1). Otherwise, it may move helically outward (cf. Fig. 4.2). (ii) If $V_1(x) = V_2(x)$ with $\gamma_{x,j} = \gamma_{y,j}$, $\beta_{12} = \beta_{21}$ and $\lambda_{12} = \lambda_{21}$, the total center of mass $x_c$ moves periodically with a period depending on both the rotating frequency and trapping frequency. In addition, the dynamics of $x_c$ does not depend on the interaction parameters $\lambda_{ij}$ and $\beta_{ij}$ ($i, j = 1, 2$), which is consistent with 3.17-3.18. (iii) If $\beta_{12} = \beta_{21}$ and $\lambda_{12} = \lambda_{21}$ and each trapping potential is symmetric but $V_1(x) \neq V_2(x)$, the interaction between two components affects the motion of $x_{c,j}$ and hence $x_c$. Unlike the single-component case where the center of mass always moves periodically, here $x_{c,j}$ moves quasi-periodically (cf. Fig. 4.1 (c) and 4.2 (f)). (iv) If the trapping potentials are not symmetric, the dynamics of center of mass becomes more complicated. Interactions between the two components will affect the dynamics pattern of center of mass significantly.

4.3. Dynamics of quantized vortex lattices

In the following, we study the dynamics of quantized vortex lattices in the rotating two-component dipolar BECs. To this end, we choose $d = 2$, $\beta_{11} = \beta_{22} = 100$, $\beta_{12} = \beta_{21} = 70$ and $\Omega = 0.9$. The trapping potentials are chosen as the harmonic ones (1.3) with $\gamma_{x,j} = \gamma_{y,j} = 1$, $j = 1, 2$. The initial datum (1.2) are chosen as the stationary vortex lattice state computed by the classical gradient-flow method [8, 45] for the chosen parameters without DDI, i.e. $\lambda_{11} = \lambda_{22} = \lambda_{12} = \lambda_{21} = 0$. The dynamics of vortex lattices are studied for the following two cases:

- Case 1: perturb the trapping frequency in component one by setting $\gamma_{x,1} = \gamma_{y,1} = 1.5$.
- Case 2: turn on the dipolar interaction in component one by setting $n = (1, 0, 0)^T$ and $\lambda_{11} = 10$.

In our simulation, we take $D = [-12, 12]^2$, $h_x = h_y = \frac{1}{8}$ and $\Delta t = 0.001$. Figure 4.3 shows the contour plots of the density function $|\psi_j(x, t)|^2$ ($j = 1, 2$) at different times for Case 1 and 2, while Fig. 4.4 shows the dynamics of the angular momentum expectation. From these two figures, we can see that: (i) The total angular momentum expectation is conserved if $\beta_{12} = \beta_{21}$, $\gamma_{x,j} = \gamma_{y,j}$ and $\lambda_{ij} = 0$ ($i, j = 1, 2$), which agrees with [3.4]. (ii) If there is no DDI and the trapping potentials are symmetric, the lattices rotate around the origin and keep a similar symmetry and pattern as the initial ones. Meanwhile, the lattices also undergo...
Figure 4.1: The dynamics of center of mass and trajectory for $0 \leq t \leq 200$ for case 1-3 in section 4.2: The first two columns for component one and the last two for component two.

a breather-like dynamics. (iii) The DDI affects the dynamics very much. Due to the anisotropic nature of DDI, the lattices will rotate to some quite different patterns. The vortices will be redistributed during dynamics. Unlike the single-component BEC, the redistribution here does not seem to be aligned with the dipole axis because of the interaction between the two components. It is interesting to further investigate how the patterns of vortex lattices reform and change with respect to the interactions as well as the dipole orientations. Here, we leave it as a further study.

4.4. Numerical results in 3D

In this subsection, we report the dynamics of non-rotating two-component dipolar BECs under different setups. To this end, unless stated otherwise, the trapping potential and initial datum are chosen respectively as

$$V_1(x) = V_2(x) = \frac{|x|^2}{2}, \quad \psi_1^0(x) = \psi_2^0(x) = \frac{1}{\sqrt{2}} \phi_{gs}(x),$$

(4.50)

where $\phi_{gs}(x)$ is the ground state of the single-component non-rotating dipolar BEC with parameters $n = (0, 0, 1)^T$, $\beta = 103.58$ and $\lambda = 0.8 \beta$. Figure 4.5 shows the isosurface of the density for the initial datum $|\psi_j^0(x)|^2 = 0.01$ $(j = 1, 2)$. The computation domain is taken as $D = [-8, 8]^3$ and the mesh sizes in spatial and temporal direction are chosen as $h_x = h_y = h_z = h = \frac{1}{8}$ and $\Delta t = 0.001$, respectively.

Example 4.1. Let $\beta_{11} = \beta_{22} = \beta$, $\lambda_{11} = \lambda$ and consider the following three cases: for $j = 1, 2$, $k_j = 3 - j$

- Case 1: let $\beta_{jk_j} = 100$ and turn off the DDI in component two, i.e. $\lambda_{22} = \lambda_{jk_j} = 0$. The dipole axis in component one is kept unchanged, i.e. $n = (0, 0, 1)^T$.  

13
Figure 4.2: The dynamics of center of mass and trajectory for $0 \leq t \leq 150$ for case 4-6 in Section 4.2 the first two columns for component one and the last two for component two.

- **Case 2**: change the dipole axis to $\mathbf{n} = (1, 0, 0)^T$ and keep the other parameters the same as in Case 1.

- **Case 3**: perturb the interatomic interaction as well as the DDI strength, i.e. $\beta_{12} = \beta_{21} = 50$, $\lambda_{22} = 0.8\beta$ and $\lambda_{jk} = 0.8(\beta_{jk})$. The dipole axis is now time-dependent: $\mathbf{n} = (\sin(t/2), 0, \cos(t/2))^T$.

Figures 4.6-4.8 depict the isosurface of the densities $|\psi_j(x, t)|^2 = 0.01$ ($j = 1, 2$) at different times. From these figures and additional results not shown here for brevity, we can see that: (i) The total energy and mass are conserved well. (ii) Phase separation of the two components may come up during dynamics (cf. Figs. 4.6-4.7). In fact, the BECs would undergo mixing and de-mixing formation cyclically. (iii) Similar as those shown in the single-component BEC [11], when the trapping potentials are isotropic, the shapes of the density profile seem unchanged and keep the same symmetric structure with respect to the dipole orientation if the dipole axis rotates slowly (cf. Fig. 4.8).

**Example 4.2.** Here we study the collapse dynamics of the dipolar BEC. To this end, we take initial data as (4.50) with same interaction parameters and dipole axis $\mathbf{n}$ under trapping potential $V_1(x) = V_2(x) = x^2 + y^2 + z^2$. Figure 4.9 shows the isosurface of the densities for the initial datum $|\psi_0(x)|^2 = 0.002$ ($j = 1, 2$). The computational domain and time step are chosen as $\mathcal{D} = [-8, 8] \times [-8, 8] \times [-4, 4]$ and $\Delta t = 0.0001$, respectively. We consider two cases of collapse dynamics: for $i, j = 1, 2$, $k_j = 3 - j$

- **Case 1**: let $\beta_{ij} = \beta$ and change the DDI strength from $\lambda_{ij} = \lambda$ to $\lambda_{11} = \lambda_{jk} = 2\lambda_{22} = 10\lambda$.

- **Case 2**: let $\lambda_{jj} = \lambda$, $\lambda_{jk} = 0$ and change $\beta_{ij} = \beta = 103.58$ to $\beta_{ij} = -600$. 

14
Figure 4.3: Contour plots of the densities $|\psi_1(x,t)|^2$ and $|\psi_2(x,t)|^2$ for Case 1 (top two rows) and Case 2 (bottom) in Section 4.3.

Figure 4.4: Dynamics of the angular momentum expectation for Case 1 (a) and 2 (b) in Section 4.3.

Figures 4.10–4.11 depict the isosurface of the densities for $|\psi_j(x,t)|^2 = 0.002$ ($j = 1, 2$) at different times, while Fig. 4.12 shows the dynamics of energies. From these figures, we can see that: (i) The densities of the dipolar BECs collapse at finite time during the dynamics, i.e. the finite time blow-up of the solution is observed. This is especially clear for case one where the contact short-range interaction are all repulsive. This reveals clearly the partial-attractive/partial-repulsive property of the DDI. (ii) The total energy and
mass are conserved well before the blow-up time. They are not conserved near or after the blow-up time since the solution can no longer be resolved with a fixed mesh size and time steps.

To sum up, Examples 4.1 and 4.2 show that the dynamics of the dipolar BECs are interesting and also very much complicated. Different structure formations occur during dynamics and they depend heavily on the dipole orientation and the ratio between the DDI and contact interaction strength. Moreover, the global existence and finite-time blow-up of the solution depend on those interaction parameters, which we leave it as future consideration.

5. Conclusions

We proposed a robust and accurate numerical scheme to compute the dynamics of the rotating two-component dipolar Bose-Einstein condensates (BEC). In rotating Lagrangian coordinates, the original coupled Gross-Pitaevskii equations (CGPE) were reformulated into new equations where the rotating term vanishes. We then developed a new time splitting Fourier pseudospectral method to simulated the dynamics
Figure 4.7: Isosurface of the densities $\rho_1(x, t) = |\psi_1(x, t)|^2 = 0.01$ (first row) and $\rho_2(x, t) = |\psi_2(x, t)|^2 = 0.01$ (second row) at different times in Example 4.1: Case II.

Figure 4.8: Isosurface of the densities $\rho_1(x, t) = |\psi_1(x, t)|^2 = 0.01$ (first row) and $\rho_2(x, t) = |\psi_2(x, t)|^2 = 0.01$ (second row) at different times in Example 4.1: Case III.

of the new equations. The nonlocal Dipole-Dipole Interactions (DDI) were evaluated with the Gaussian-sum (GauSum) solver [22], which help achieve spectral accuracy within $O(N \log N)$ operations, where $N$ is total number of grid points. Our method is proved to be robust and efficient, and it has spectral accuracy in space and second order accuracy in time. Dynamical laws of total mass, energy, center of mass and angular momentum expectation are derived and confirmed numerically. We then applied the scheme to study the dynamics of quantized vortex lattices, the collapse dynamics of 3D dipolar BECs and identified some
Figure 4.9: Isosurface of the initial densities $\rho_0^1(x) = |\psi_0^1(x)|^2 = 0.002$ (a) and $\rho_0^2(x) = |\psi_0^2(x)|^2 = 0.002$ (b) in Example 4.2.

Figure 4.10: Isosurface of the densities $\rho_1(x,t) = |\psi_1(x,t)|^2 = 0.002$ (first row) and $\rho_2(x,t) = |\psi_2(x,t)|^2 = 0.002$ (second row) at different times for collapse of Case 1 in Example 4.2.

phenomena that are peculiar to the rotating two-component dipolar BECs.
