INTRODUCTION

Glioma is the most common malignant tumor of the central nervous system with rapid progress, strong aggression, and high rate of relapse.1 Despite increasing progress in surgery, chemotherapy, and radiotherapy, the expected survival time is only 12 to 15 months for late diagnosis and advanced stages.2,3 However, molecular targeted agents have therapeutic effects in the treatment...
of malignant tumors, such as EGFR- and ALK-sensitive lung cancer and VEGF-sensitive colorectal cancer. Monoclonal antibodies and tyrosine kinase inhibitors have played an important role in the treatment of breast cancer, gastrointestinal stromal tumor, and melanoma as the main targeted therapy agents. Candidates for targeted therapy include tumor growth factor receptor, signal transduction molecule, apoptosis regulatory factor, proteolytic enzyme, and vascular endothelial growth factor. Hence, explorations in the molecular pathological mechanism of glioma and sequentially appropriate biomarker selection are indispensable to precise treatment of glioma.

Paf1C, composed of Paf1, Leo1, CTR9, Cdc73, and Rtf1, is involved in the malignant progression of many tumors, such as pancreatic carcinoma, ovarian cancer, Wilms tumor, and breast cancer. Among the five subunits, CTR9 independently plays significant roles in many biological processes of transcription, such as transcription, ubiquitination, and cell cycle. Interestingly, CTR9 functions as a tumor suppressor in Wilms cancer, and however, the expression of CTR9 is up-regulated in breast carcinoma. Till now, whether CTR9 plays as a tumor promoter or suppressor in glioma cells awaits investigation and clarification.

Former researches have found that the activity of STAT3 in tumors was abnormally activated with high frequency, such as glioma, liver cancer, colon cancer, breast cancer, lung cancer, and stomach cancer. Its activation degree is significantly related to the poor prognosis of cancer patients. The JAK2 / STAT3 pathway is a key pathway for STAT3 signal transduction and transcriptional activation. Studies have shown that the JAK and STAT were overexpressed in most malignant tumors, especially the abnormal activation of STAT3. Normally, STAT3 functions in the cytoplasm, it was transferred into the nucleus once activated and caused abnormal transcription of target genes. STAT3 can facilitate the development of malignant tumors by regulating downstream molecules, such as c-Myc, cyclin-D1, MMP-2, VEGF, Bcl-2, and Bax. Through its own functions and its regulation of downstream molecules, it is involved in the process of proliferation, migration, and invasion of various tumors. Therefore, we speculate that CTR9-mediated JAK2/STAT3 pathway may explain the malignant behaviors of glioma.

In our study, we first detected the expression of CTR9 protein in glioma patients’ tissues and glioma cell lines by Western blotting assay. Then, the role of CTR9 in glioma was studied through a variety of functional experiments. Finally, we proved that CTR9 facilitates proliferation, migration, and invasion through regulating JAK2/STAT3 pathway.

2 | MATERIALS AND METHODS

2.1 | Antibodies

Antibody against CTR9 was purchased from Cell Signaling Technology. JAK2, p-JAK2, STAT3, p-STAT3, and β-actin antibodies were bought from Proteintech.

2.2 | Tissue samples

Twenty-two fresh brain tissue specimens from glioma and six fresh brain tissue specimens from traumatic brain injury were selected randomly from the specimen repository in Nanjing Brain Hospital. All tissues were taken from the central site of the resected tumors with typical morphology and pathologically confirmed diagnosis.

The selected samples included non-tumor group (6 cases), grade II group (8 cases), grade III group (8 cases), and grade IV group (6 cases), according to the WHO tumor classification standard.

2.3 | Cell culture

The glioma cell lines U251, T98G, and human embryonic kidney cell line HEK293T were purchased from the Shanghai Cell Bank of the Chinese Academy of Sciences. All cells were cultured in DMEM with 10% fetal bovine serum in a 37°C constant temperature incubator containing 5% CO2.

2.4 | Construction of lentivirus

Three short hairpin RNAs (shRNAs) were designed to knock down CTR9 and synthesized as follows:

2.5 | Establishment of U215 and T98G cell lines

Control, shCTR9#3, GFP, and GFP-CTR9 plasmids were co-transfected with helper plasmids pMD2.G and pSPAX2 in HEK293T cells, respectively. Virus supernatants were collected 48 h after transfection. U215 and T98G cells were infected by obtained lentiviruses and stably expressed Control, shCTR9#3, GFP, and GFP-CTR9 after puromycin filtration.

2.6 | EdU assay

Cells at the logarithmic phase were inoculated into 96-well plates. EdU assay was conducted after overnight culture. Diluted reagent
To explore the role of CTR9 in human gliomas, we used GEPIA Web server to analyze the expression of CTR9 mRNA in glioma and the relationship between CTR9 expression and survival of glioma patients. The results showed that CTR9 mRNA expression was significantly increased in both low-grade glioma (LGG) and glioblastoma (GBM) tissues, compared with normal brain tissues (Figure 1A). Also, we found that high expression of CTR9 in glioma patients indicated poor prognosis (p < 0.05, Figure 1B). To verify these data, we sequentially detected CTR9 expression in non-tumor and tumor brain tissues by Western blot. It showed that CTR9 expression level in glioma tissues was significantly increased compared with non-tumor tissues, particularly in Grade IV gliomas (Figure 1C,D). These obtained results revealed that both mRNA and protein level of CTR9 were overexpressed in human glioma tissues, indicating that CTR9 may act as an important role in human gliomas.

3.2 | Down-regulation of CTR9 restrains the proliferation, migration, and invasion of glioma cells

To study the effects of CTR9 on malignant behaviors of glioma cells, we downregulated CTR9 expression in glioma cells by its specific shRNAs and reevaluated the proliferation, migration and invasion abilities of glioma cells. First, we constructed three shRNAs (shCTR9#1, shCTR9#2 and shCTR9#3) and found shCTR9#3 owned highest efficiency in suppressing CTR9 expression (Figure 2A–C). Then, we cultured the stable downregulated CTR9 and control cell lines with lentivirus packaged by shCTR9#3 and control. After that, we studied whether silencing CTR9 has a negative or positive effect on cell proliferation.

The EdU incorporation assay showed that the EdU-positive cells in CTR9-silenced U251 cells decreased by 50%, while decreased by 25% in CTR9-silenced T98G cells, compared with their respective control group (Figure 2D,E). Also, the CCK-8 assay showed down-regulation of CTR9 suppressed cell viability in glioma cells (Figure 2F,G). The results above showed that CTR9 was involved in the proliferation of human glioma cells and down-regulation of CTR9 inhibited the proliferation of glioma cells.

To explore the role of CTR9 on the migration and invasion of glioma cells, we conducted transwell assay. The transwell migration assay (+Matrigel) indicated that down-regulation of CTR9 suppressed the cell migration in U251 and T98G cells (Figure 2H,I). The transwell invasion assay (+Matrigel) showed the number of invasive CTR9-silenced U251 and T98G cells decreased by 45% and 50%, compared to the control group (Figure 2J,K). Repeated results manifested that silencing CTR9 inhibits migration and invasion of glioma cells.

3.3 | Overexpression of CTR9 promotes the proliferation, migration, and invasion of human glioma cells

Additionally, in order to further clarify the effect of CTR9 on glioma cell proliferation, migration, and invasion, we overexpressed GFP-CTR9 in U251 and T98G cells and explore the effects from another angle. The expression efficiency was testified by Western bloting
EdU incorporation assay showed that EdU-positive cells in CTR9-overexpressed U251 and T98G cells increased by 50% and 30% compared with respective GFP group (Figure 3B,C). Also, CCK-8 assay manifested that CTR9 promoted the proliferating ability of U251 and T98G cells compared with the control groups. The transwell migration assay (-Matrigel) showed that overexpression of CTR9 promoted the cell migration in U251 and T98G cells (Figure 3F,G). The transwell invasion (+Matrigel) assay displayed that the number of invading U251 and T98G cells increased by 90% and 70% after CTR9 overexpression (Figure 3H,I). These results suggested that CTR9 is involved in the proliferation, migration, and invasion of human glioma cells and acts as a tumor promoter.

3.4 CTR9 promotes the proliferation, migration, and invasion of human glioma cells by regulating JAK2/STAT3 pathway

Previous reports have shown that CTR9 could activate STAT3 signaling. Furthermore, it is acknowledged that JAK2/STAT3 pathway is involved in growth and motility of human cancers. Based on these, we supposed that CTR9-mediated JAK2/STAT3 pathway may play a significant role in proliferation, migration, and invasion of human glioma cells. We confirmed our inference by Western blot. The results showed that STAT3 and p-STAT3 were decreased in CTR9 knockdown U251 and T98G cells, and however,
the expression of STAT3 and p-STAT3 was increased in CTR9-overexpressed U251 and T98G cells (Figure 4A–C). Moreover, the expression of JAK2 and p-JAK2, the upstream regulator of STAT3, was decreased upon silencing CTR9, but enhanced upon overexpressing CTR9 (Figure 4D–F). Furthermore, to confirm that CTR9 regulates STAT3 by activating JAK2, we applied JAK2 inhibitor SB1317 to conduct the rescue experiment. As expected, overexpression of CTR9 up-regulated JAK2, p-JAK2, STAT3, and p-STAT3. However, this up-regulation could be significantly blocked by JAK2 inhibitor SB1317 (Figure 5A–C). The results demonstrated that STAT3 and p-STAT3 up-regulation induced by CTR9 were attributed to JAK2 and p-JAK2 activation. In addition, we conducted CCK-8 and transwell assays to confirm this in the presence of the JAK2 inhibitor. As the results showed, JAK2 inhibitor SB1317 blocked cell proliferation (Figure 5D,E), migration (Figure 5F,G), and invasion (Figure 5H,I). In all, the results expounded that CTR9-mediated JAK2/STAT3 pathway could accelerate proliferation, migration, and invasion of glioma cells.

4 | DISCUSSION

CTR9 is a multi-functional gene that is implicated in many cellular processes such as cell cycle, transcription, neurogenesis, and embryonic organogenesis. Former researches have shown that CTR9 functions as a tumor suppressor in Wilms tumor while drives ERα-positive breast tumorigenesis, which indicates that CTR9 is a potential candidate for human tumor biomarkers. However, the
expression of CTR9 and its clinical relevance in glioma patients have never been clearly elaborated. In our present study, we detected that CTR9 was up-regulated in human glioma tissues compared with tissues derived from normal brain. In addition, we drew a conclusion that high expression of CTR9 was strongly associated with poor prognosis of glioblastoma patients through public database analysis. We clarified that up-regulation of CTR9 in glioma cells could accelerate proliferation, migration, and invasion of glioma cells by regulating the JAK2/STAT3 pathway. These findings suggest that CTR9 exerts as a tumor-promoting role in glioma and is a promising therapeutic strategy in human brain glioma.

It is widely acknowledged that silencing of specific tumor suppressor genes and activation of certain oncogenes are responsible for the occurrence and malignant progression of glioblastoma. In particular, JAK2/STAT3 pathway is deeply involved in the survival and motion of tumor cells. The excessive activation of JAK2 signaling in glioma is accelerated by abnormal signals from upstream regulators. This usually involves any gain-of-function mutations or up-regulation of upstream inhibitors, and, on the other hand, any loss-of-function mutation or down-regulation of the upstream inhibitors. In this study, we found that CTR9 could promote glioma cell proliferation, migration, and invasion by modulating JAK2/STAT3 pathway. That is to say, up-regulation of CTR9 may be a significant event in the development and malignant progression of human glioma.

STAT3 plays a strong inhibitory role on cell apoptosis through JAK2/STAT3 pathway, and its continuous activation of cells is deeply involved in the occurrence and progression of human malignant...
tumors. Phosphorylated Stat3, once transferred into the nucleus, can regulate the transcription of some target genes involved in basic physiological functions and induce the abnormal expression of genes closely related to cell proliferation, differentiation, and apoptosis, such as Bcl-XL and c-Myc, promoting cell proliferation and malignant transformation. In the present study, we found that Stat3 and p-STAT3 were significant up-regulated upon CTR9-induced activation of JAK2 pathway. Besides, the overexpression of STAT3 and acceleration of glioma cell proliferation, migration, and invasion induced by up-regulation of CTR9 could be distinctly blocked by JAK2 inhibitor.

Taken together, we affirmed the association between the CTR9-mediated JAK2/STAT3 pathway and the malignant behaviors of glioma. Our findings provided a basis for potential therapeutic target and prognosis evaluation in glioma. However, more sequent researches are urgent to be conducted to clarify the precise mechanisms of CTR9-mediated activation of JAK2/STAT3 pathway in human glioma.

ACKNOWLEDGEMENTS
We would like to thank Dr. Liang Zhao for critical review of this manuscript.

CONFLICT OF INTERESTS
