INTRODUCTION

The humoral immune response is crucial for protecting individuals from many infections and eliminating foreign substances. Antibody responses can be induced in a T cell dependent or T cell independent manner. In T-independent immunity, the antibody response occurs directly after B cell activation in T cell deficient mice. In contrast with T-independent responses, T-dependent responses require T cell help for B cell activation and maturation. In the presence of T cell help, B cells undergo robust proliferation and somatic hypermutation of their variable region genes and differentiate into high affinity memory B cells and long-lived plasma cells in the germinal centers (1, 2). Although several subsets of CD4+ T cells may be implicated in T-dependent humoral responses, it becomes clear that the follicular helper CD4+ T cell subset [T follicular helper (Tfh)] is a major B cell help provider (3–6). Tfh cells exhibit a phenotype distinct from that of other effector CD4+ T helper cells, as they express the transcription factor B cell lymphoma 6 (Bcl6) that is necessary for the development of Tfh cells and inhibits expression of genes critical for development of other T helper cells (4, 7–9). Although Bcl6 expression by pre-Tfh cells is required, it is not sufficient in vivo for full polarization of Tfh cells. In fact, multiple molecules have been shown to be involved in the differentiation of Tfh cells (3, 4, 6). In addition, Tfh development is highly dependent on B cell responses, as Tfh cells are not found in B cell deficient mice (7, 10, 11). These findings indicate that, through their interaction, GC B cells and Tfh cells reciprocally provide each other with signaling for survival, proliferation, and differentiation.

The signaling lymphocytic activation molecule family (SLAMF) includes nine structurally related Ig-like proteins that are differentially expressed on the surface of hematopoietic cells (12). SLAMF receptors have been shown to function as co-stimulatory molecules and to modulate the activation and differentiation of a wide array of immune cell types involved in both innate and adaptive immune responses (12–14). While most SLAMF receptors serve as self-ligands, SLAMF2 and SLAMF4 interact with each other. Six SLAMF receptors (SLAMF1, SLAMF3, SLAMF4, SLAMF5, SLAMF6, and SLAMF7) carry one or more copies of an immunoreceptor tyrosine-based switch motif (ITSM) in their cytoplasmic tails. This signaling switch motif can recruit SH2 domain-containing signaling molecules such as SLAM-associated protein (SAP) (15). SAP is a cytoplasmic adapter molecule with a single Src homology 2 domain-containing signaling molecules such as SLAM-associated protein (SAP) (15). SAP is a cytoplasmic adapter molecule with a single Src homology 2 domain and a small carboxy-terminal region. The SAP family consists of three members: SAP expressing T, NK, and NKT cells, and EAT-2A and EAT-2B (murine) expressing NK cells and APC (12, 16). There is accumulating evidence that SAP and EAT-2 can function as signaling adaptors that link SLAMF receptors to active signaling molecules such as the Src...
family protein tyrosine kinases Fyn and PI3K (15, 17–21). SAP and EAT-2 have also been shown to act as blockers to outcompete SH2 domain-containing inhibitory molecules SHP1, SHP2, and SHIP1 (22–28).

Deficiencies in the gene that encodes SAP (SH2D1A) result in a primary immunodeficiency called X-linked lymphoproliferative disease (XLP) (29–31). Patients with XLP suffer from fatal infectious mononucleosis, malignant B cell lymphomas, and dysgammaglobulinemia. Defects in humoral responses and lack of germinal center formation are observed in XLP patients and in virally infected or immunized SAP-deficient mice (32–36). Considerable evidence indicates that the humoral immune response defect in XLP patients and SAP−/− mice stems from a defect in CD4+ helper cells because T-dependent antigen responses are defective and are restored after reconstitution with WT CD4+ T cells, but not WT B cells (32, 34, 35). However, the role of SAP in T-dependent humoral responses remains unclear. The SLAM/SAP/Fyn axis regulates IL-4 producing Th2 differentiation, as demonstrated by the observation that Slamd1−/− and SAP−/− mice have defective Th2 cytokine secretions (37–39). IL-4 is known to stimulate B cell antibody responses and Ig class switching, but the R78A mutant SAP mice can mount normal T-dependent antibody responses even though this mutant SAP molecule loses Fyn binding motif R78 (40). Recently, Qi and co-workers elegantly showed that SAP-deficient CD4+ T cells cannot form lasting mobile conjugate pairs with cognate B cells in the germinal center while the interaction between SAP-deficient T cells and DC is not affected (41). Since a sustained T-B conjugate allows their comprehensive activation and subsequent differentiation to Th2 cells and GC B cells, unstable T-B cell conjugates may contribute to humoral immune deficiency in SAP-deficient mice and XLP patients.

Compared to severe immunodeficiencies in SAP−/− mice, single ablation of SLAMF receptors causes a mild phenotype (40, 42–44). When mice deficient in SLAMF1 (the prototypic member of the SLAMF receptors) were infected with LCMV, Th cell differentiation, germinal center development, and the acute or long-term anti-viral antibody responses were comparable between LCMV-infected WT and Slamd1−/− mice (40). Similar to Slamd1−/− mice, Slamd5−/−, Slamd6−/−, and Slamd6−/− mice showed no defects in response to LCMV (28, 42). This suggests that functional redundancy exists among the SLAMF receptors, which has been confirmed in NKT cell development in pseudo Slamd1+6+-deficient bone marrow reconstituting mice (45) and recent Slamd1+6+-/- mice (46). For more than a decade, investigating the role of SLAMF receptors in SAP-mediated signaling has been difficult due to an inability to generate double or multiple SLAM receptor deficient mice, as the receptors are closely located on the same chromosome (12). To define roles of SLAMF receptors as well as how they interact with one another in humoral immune responses, we generated Slamd1+6+ double knockout and Slamd1+5+6 triple knockout mice using a two-time gene targeting technique and Cre/LoxP system. Surprisingly, we found that the combined absence of SLAMF1, SLAMF5, and SLAMF6 results in higher antibody production in response to both T-dependent and T-independent antigens. In addition, the administration of anti-SLAMF6 monoclonal antibody also impairs humoral immune responses in vivo. These observations suggest that SLAMF1, SLAMF5, and SLAMF6 function as negative regulators in T-dependent and T-independent antibody responses.

**MATERIALS AND METHODS**

**MICE**

To generate Slamd1+6+/- and Slamd1+5+6+/- mice, a B6 bacterial artificial chromosome clone (B6 BAC clone #RP23-77A8) containing the Slamd1 and Slamd6 genes was used to construct a targeting vector with a neomycin resistant cassette flanked by two LoxP sites. SLAMF6 ES cell clones heterozygous for the mutation were generated by standard methods. To generate Slamd1 and Slamd6 double-deficient mice, we used a SLAMF1 targeting vector to retarget the previously generated SLAMF6 mutant ES cell clone that was known to give germine transmission with extremely high frequency. Co-integration of the two targeting vectors on the same chromosome was assessed by in vitro transfection-targeted ES cell clones with a Cre recombinase expression vector. Deletion of the whole Slamd1, Slamd2, and Slamd6 locus was confirmed by PCR (Figures 1A,B). B6 background Slamd5+/- mice have been reported previously (46). Wild-type C57BL/6 (B6) mice were obtained from the Jackson Laboratory. Animal studies were conducted in accordance with the National Research Council’s Guide for the Care and Use of Laboratory Animals and were approved by the Beth Israel Deaconess Medical Center Institutional Animal Care and Use Committee.

**ANTI-SLAMF RECEPTOR ANTIBODIES**

Rat anti-mouse SLAMF1 mAb (9D1) is specific for the extracellular region of mouse SLAMF1 (25). The anti-mouse SLAMF5 mAb was generated by fusing NS1 myeloma cells with spleen cells obtained from Armenian hamsters, which were immunized three times with mouse SLAMF5-Fc fusion protein (47). Mouse anti-mouse SLAMF6 mAbs (13G3 and 330) are specific for the extracellular region of mouse SLAMF6. Anti-SLAMF1, anti-SLAMF5, and anti-SLAMF6 mAbs used in our studies were purified by affinity chromatography (Harlan Bioproducts for Science). Anti-SLAMF6 F(ab)2 fragments were generated from whole SLAMF6 mAb, using the Thermo Scientific Pierce F(ab’)2 Preparation Kit (PI-44988) according to manufacturer instructions.

**IMMUNIZATION**

Mice were immunized intraperitoneally (i.p.) with 40 µg of NP-ovalbumin (NP-OVA, Biosearch Technology) precipitated with Complete Freund’s Adjuvant (Difco) or Alum. For eliciting T independent antigen responses, mice were i.p. immunized with 20 µg of NP28-Ficoll (Biosearch Technologies) or with 10 µg NP-LPS. Mice were bled on day 9 (for T-dependent antigen) or day 7 (for T-independent antigen) post-immunization. NP-specific IgG and IgM titers were determined by ELISA after serial dilutions of the serum.

**ADOPTIVE CELL TRANSFER**

Naïve CD4+ and B220+ B cells were purified from the spleens of WT and Slamd1+5+6+/- mice using a magnetic cell sorting kit (Miltenyi Biotec). Rag-1-/- recipient mice were injected with 5 x 10^6 CD4+ T cells and 10 x 10^6 B220+ B cells in 200 µl PBS.

FLOW CYTOMETRY

Mice were immunized with NP-OVA/CFA 7 days after adoptive cell transfer.

RESULTS

GENERATION OF Slamf1+6−/− AND Slamf1+5+6−/− MICE

Since the murine SLAMF1, SLAMF5, and SLAMF6 genes are closely linked on mouse chromosome 1, a mouse strain lacking Slamf1+6/ or Slamf1+5+6/ cannot be generated by interbreeding individual Slamf1+6−/−, Slamf5−/−, and Slamf6−/− mice. To generate Slamf1+6−/− and Slamf1+5+6−/− mice, we first replaced exons 2 and 3 of the Slamf6 gene with a LoxP-flanked PKG-NeoR cassette in the first targeting event in B6 ES cells (Figure 1A). We next transfected one of the SLAMF6-targeted ES cell clones with a vector that replaced exons 2 and 3 of the Slamf1 gene with a hygromycin resistant gene containing a LoxP site, thus generating Slamf1+6−/+ ES cells. To identify ES cell clones in which both insertions had taken place on the same chromosome, we removed the LoxP-flanked chromosome fragment of 200 Kb, which includes the Slamf1, Slamf5, and Slamf6 genes. The confirmed Slamf1+6−/+ ES cell clones were used to generate Slamf1+6−/− mice. Subsequently, Slamf1+6−/− mice were bred to CreTg mice to obtain Slamf1−/− mice. Thymocytes from WT, Slamf1−/−, and Slamf6−/− mice were stained with anti-SLAMF1, anti-SLAMF5, and anti-SLAMF6 antibodies, and the expression of SLAMF1, SLAMF5, and SLAMF6 was evaluated by flow cytometry.

THE NUMBER OF MARGINAL ZONE B CELLS IS SIGNIFICANTLY INCREASED IN Slamf1+5+6−/− MICE

Thymic development and the number of splenic T cells were not altered in Slamf1+6−/− or Slamf1+5+6−/− mice (Figures S1A,C in Supplementary Material). However, a close examination of the B cell compartment by flow cytometric analysis revealed that the number and percentage of marginal zone (MZ) B cells (slgM+AA4.1+CD19+CD21hiCD23lo−neg) was significantly increased in Slamf1+5+6−/− mice as compared to WT and Slamf1+6−/− mice (Figures 2A–C). By contrast, the percentage and number of T and B cells and the number of splenocytes in Slamf1+5+6−/− mice were identical to those in WT mice (Figure 2D; Figures S1A–C in Supplementary Material). The population of follicular B cells (AA4.1−CD21+CD23+slgMint) in the

April 2015 | Volume 6 | Article 158 | 3
spleens of \textit{Slamf}1\(^{+}\)\textit{Slamf}5\(^{-}\) mice and \textit{Slamf}6\(^{-}\) mice was similar to that in WT mice (Figure 2E). Similarly, the frequencies of CD5\(^{+}\) B1a and CD5\(^{-}\) B1b cells were comparable in the peritoneal cavity of mutant and WT mice (Data not shown). Immature peripheral B cells can be divided into three transitional populations based on their surface marker expression, designated as transitional type 1 (T1) (AA4.1\(^{+}\)\textit{slamf}1\(^{-}\)CD21\(^{-}\)), transitional type 2 (T2) (AA4.1\(^{+}\)\textit{slamf}1\(^{-}\)CD23\(^{-}\)), and transitional type 3 (T3) (AA4.1\(^{+}\)\textit{slamf}5\(^{-}\)CD23\(^{+}\)). Similarly, the frequencies of T1, T2, and T3 immature B cell populations in \textit{Slamf}1\(+\)6\(^{-}\) and \textit{Slamf}1\(+\)5\(^{-}\)6\(^{-}\) mice were not significantly different from those of wild-type mice (Figure 2F). Collectively, these findings show that the ablation of \textit{Slamf}1, \textit{Slamf}5, and \textit{Slamf}6 affects the development of MZ B cells, but other B cell subsets and T cell development occur normally in \textit{Slamf}1\(+\)6\(^{-}\) and \textit{Slamf}1\(+\)5\(^{-}\)6\(^{-}\) mice.

\section*{Enhanced T Cell Dependent Antibody Production in \textit{Slamf}1\(+\)5\(^{-}\)6\(^{-}\) Mice}

Although most \textit{Slamf} receptors are expressed on the surface of T and B cells, ablation of single \textit{Slamf} genes does not lead to significant defects in germinal center formation after protein immunization or viral infection (27, 42, 44). In contrast, the absence of SAP, the \textit{Slamf} specific adaptor, leads to a severe defect in humoral response (14, 32, 34), which suggests functional redundancies in the control of antibody responses by \textit{Slamf} receptors. To test this hypothesis, we compared NP-specific antibody production by \textit{Slamf}1\(+\)6\(^{-}\), \textit{Slamf}1\(+\)5\(^{-}\)6\(^{-}\), and WT mice. \textit{Slamf}1\(+\)6\(^{-}\) mice, which had been immunized with NP-OVA in CFA, produced similar amounts of NP-specific serum IgM as WT mice (data not shown). However, the level of anti-NP IgG in the serum of \textit{Slamf}1\(+\)6\(^{-}\) mice was consistently higher, although statistical analysis did not reach significance (Figure 3A). Surprisingly, the additional disruption of the \textit{Slamf}5 gene significantly augmented the level of anti-NP IgG in \textit{Slamf}1\(+\)5\(^{-}\)6\(^{-}\) mice (Figure 3A) even though NP-specific IgM production was not altered (data not shown). Affinity maturation of NP-specific IgG was comparable between the mutant and WT mice (data not shown). Because \textit{Slamf}1\(+\)5\(^{-}\)6\(^{-}\) mice produced higher NP-specific IgG compared to \textit{Slamf}1\(+\)6\(^{-}\) mice, we reasoned that \textit{Slamf}5 signaling might suppress antibody responses. To test this, we then immunized \textit{Slamf}5\(^{-}\) mice with NP-OVA. In contrast to a previous report (41), \textit{Slamf}5 deficiency had no effect on NP-specific antibody production or the development of Tfh cells or GC B cells (Figure 3F). Taken together, the data support the notion that \textit{Slamf}1, \textit{Slamf}5, and \textit{Slamf}6 cooperate in the negative regulation of T-dependent antibody responses.

\section*{The Combined Absence of \textit{Slamf}1, \textit{Slamf}5, and \textit{Slamf}6 Enhances Antigen Specific Plasma Cell Expansion, But Has No Effect on the Development of GC B Cells, Tfh Cells, or TFOLlicular Regulatory (Tfr) Cells}

As strong humoral immune responses, characterized by GC formation and long-lived plasma and memory B cells, are dependent on help provided by CD4\(^{+}\) Tfh cells (4, 5, 48), we next examined whether enhanced T-cell dependent antibody responses in \textit{Slamf}1\(+\)5\(^{-}\)6\(^{-}\) mice are correlated with an increase in Tfh cell differentiation and higher germinal center responses after immunization with NP-OVA. Contrary to our prediction, the percentage and number of Tfh cells was comparable between \textit{Slamf}1\(+\)5\(^{-}\)6\(^{-}\) and WT mice (Figure 3C; Figure S2A in Supplementary Material). Percentages of GC B cells (FAS\(^{+}\) GL-7\(^{+}\)) were also unaffected by the combined absence of \textit{Slamf}1, \textit{Slamf}5, and \textit{Slamf}6 (Figure 3E; Figure S2B in Supplementary Material).
Wang et al. SLAMF1, SLAMF5, and SLAMF6 are negative regulators

Furthermore, flow cytometric analysis confirmed an increase in NP-specific plasma cells in immunized Slamf1−5+6−/− mice as compared to wild-type mice (Figures 4C, D). Together, the data indicate that the absence of SLAMF1, SLAMF5, and SLAMF6 has no effect on Tfh and GC B cell development, but that it appears to regulate development of antigen specific plasma cells.

A new Treg cell subset termed Tfr cells has recently been identified (49, 50). These cells, which express not only CXCR5 and PD-1 but also the transcription factors Bcl6 and FoxP3, suppress both Tfh cells and GC B cells. As Tfr cell differentiation requires SAP expression (49), it is possible that the absence of SLAMF1, SLAMF5, and SLAMF6 might also cause a defect in Tfr cell development, thereby contributing to the enhanced antibody responses in Slamf1−5+6−/− mice. To assess the impact of the combined absence of SLAMF1, SLAMF5, and SLAMF6 on Tfr cell development, we immunized mice with NP-OVA and analyzed Tfr cells 7 days later. The frequency of Tfr cells (CD4+CXCR5+PD-1hhighFoxP3+) was not significantly affected in Slamf1−5+6−/− or Slamf1−5+6−/− mice (Figure S3A in Supplementary Material). Although the expression of K67, a marker used to identify proliferating cells, is slightly decreased in Slamf1−5+6−/− Tfr cells, it is not statistically significant (Figure S3B in Supplementary Material). Thus, while the enhanced antibody production may not result from a defect in Tfr differentiation, its functional inability would not be excluded in Slamf1−5+6−/− mice.

SLAMF1−5+6−/− B OR T CELLS ADOPTIVELY TRANSFERRED TO RAG-1 DEFICIENT MICE CAN INDUCE ENHANCED ANTIBODY RESPONSES

As SLAMF1, SLAMF5, and SLAMF6 are expressed on both B cells and T cells, it was not clear on which cell type ablation of their expression was critical for the altered T-dependent antibody responses observed in Slamf1−5+6−/− mice. This prompted us to evaluate potential contributions of Slamf1−5+6−/− T and B cells to the enhanced humoral responses by using the adoptive transfer of naïve T and B cells. To this end, four combinations of CD4+ cells and B cells were transferred into Rag-1−/− recipient mice: WT CD4+ T and WT B cells, Slamf1−5+6−/− CD4+ T and Slamf1−5+6−/− B cells, WT CD4+ T and Slamf1−5+6−/− B cells, and Slamf1−5+6−/− CD4+ T and WT B cells. Seven days post-transfer, the recipient Rag-1−/− mice were immunized with NP-OVA in CFA. Rag-1−/− mice reconstituted with CD4+ T cells and B cells from Slamf1−5+6−/− mice had significantly higher NP-specific antibody production than recipient mice that had been reconstituted with WT CD4+ T cells and B cells (Figure 5). Interestingly, the transfer of Slamf1−5+6−/− B cells together with WT CD4+ T cells was sufficient to induce a stronger antibody response as compared to the transfer of WT CD4+ T cells and B cells. Although the transfer of Slamf1−5+6−/− CD4+ T cells and WT B cells also led to increased titers of NP-specific IgG, the magnitude of the antibody responses was less pronounced (Figure 5). Thus, we concluded that Slamf1−5+6−/− T and B cells both have intrinsic activity, but that the enhanced T-dependent humoral response in Slamf1−5+6−/− mice mainly results from Slamf1−5+6−/− B cells.

**FIGURE 3 | A combination of SLAMF1, SLAMF5, and SLAMF6 negatively regulates T cell dependent antibody responses, but normal Tfh and GC B development is observed in Slamf1−5+6−/− mice.** WT, Slamf1−5−/−, Slamf1−5+6−/−, and Slamf1−5+6−/− mice were immunized with 40 μg of NP-OVA and serum was collected on day 9. (A) NP-specific IgG titers for Slamf1−5+6−/−, Slamf1−5+6−/−, and WT mice immunized with NP-OVA in CFA were determined by ELISA using NP48/BSA coated plates. (B) NP-specific IgG titers for Slamf1−5−, Slamf1−5+6−/−, and WT mice immunized with NP-OVA in Alum were determined by ELISA using NP48/BSA coated plates. (C) Percentage of Tfh cells (CD4+PD-1+CXCR5+) in the spleens of Slamf1−5+6−/−, Slamf1−5+6−/−, and WT mice. (D) Percentage of Tfh cells (CD4+PD-1+CXCR5+) in the spleens of Slamf1−5−, Slamf1−5+6−/−, and WT mice. (E) Percentage of Germinal Center B cells (B220+GL7+Fas+) in the spleens of Slamf1−5+6−/−, Slamf1−5+6−/−, and WT mice. (F) Percentage of Germinal Center B cells (B220+GL7+Fas+) in the spleens of Slamf1−5−, Slamf1−5+6−/−, and WT mice. Data represent at least three independent experiments.

Given the increased antibody responses observed in Slamf1−5+6−/− mice, we hypothesized that the absence of SLAMF1, SLAMF5, and SLAMF6 may enhance either plasma cell differentiation or their capacity to produce antibody. To test this hypothesis, we evaluated NP-specific plasma cells in NP-OVA immunized mice. Consistent with high IgG responses, the frequency of plasma cells (B220+IgD−CD138+) was significantly increased in Slamf1−5+6−/− mice (Figures 4A, B).
SLAMF1, SLAMF5, and SLAMF6 are negative regulators of responses to NP-LPS were not altered (data not shown), the Ag-specific B cells to expand, differentiate, and produce NP-specific antibodies are affected in anti-SLAMF6 (330) mice (Figure 4A,B). In contrast, NP-specific IgM and IgG3 titers were comparable in WT and anti-SLAMF6 injected mice (Figures 8A,B). As responses to NP-LPS were not altered (data not shown), the enhanced T-II responses are specifically linked to the combined absence of SLAMF1, SLAMF5, and SLAMF6.

**ENHANCED T-INDEPENDENT ANTIBODY RESPONSES ARE OBSERVED IN Slamf[1 + 5 + 6]−/− MICE**

Because Slamf[1 + 5 + 6]−/− mice have a high frequency of MZ B cells (Figures 2A,B) that are known to participate in responses to T-independent antigens, we questioned whether T-independent antibody responses are affected in Slamf[1 + 5 + 6]−/− mice. Consequently, we examined the SLAMF mutant mice in response to NP-Ficoll, a classical synthetic TI-2 antigen that induces murine Ag-specific B cells to expand, differentiate, and produce NP-specific antibodies. As anticipated, the serum concentrations of NP-specific IgM and IgG3 in Slamf[1 + 5 + 6]−/− mice were increased on day 7 after immunization compared to those in WT mice (Figures 6A,B). In contrast, NP-specific IgM and IgG3 titers were comparable in WT and Slamf[1 + 5 + 6]−/− mice (Figures 6A,B). As responses to NP-LPS were not altered (data not shown), the enhanced T-II responses are specifically linked to the combined absence of SLAMF1, SLAMF5, and SLAMF6.

**ANTI-SLAMF6 ANTIBODY INHIBITS HUMORAL IMMUNE RESPONSES**

The observation that the ablation of SLAMF1, SLAMF5, and SLAMF6 enhances T-dependent and T-independent antibody responses suggests that they function as potential inhibitory molecules in humoral immune responses. In addition, a recent report indicates that SLAMF6 transmits inhibitory signaling in Th1 differentiation and NKT development in the context of the absence of SAP (27). To directly evaluate whether triggering of a single SLAMF receptor would initiate inhibitory signaling in humoral responses, we first sought to trigger SLAMF6 by using anti-SLAMF6 mAb in NP-OVA-immunized mice. As shown in Figure 7, the treatment of WT mice with anti-SLAMF6 (330) dramatically impaired NP-specific IgG production 9 days post-immunization of NP-OVA (Figure 7A). As negative control, anti-SLAMF6 had no detectable effects on antibody production in Slamf[1 + 6]−/− mice (Figure S4A in Supplementary Material). Noticeably, anti-SLAMF6 injected mice had a significant reduction in IgG high affinity antibody (Figure 7B). Furthermore, NP-specific IgM production and its affinity maturation also were impaired in anti-SLAMF6 injected mice (Figures 7C,D). In correlation with the impaired antibody response, the frequencies and absolute numbers of splenic GC B cells (GL7+ Fas+) (Figures 8A–C) and Th1 T cells (CXCR5+PD-1+) (Figures 9A–C) were significantly reduced in anti-SLAMF6 injected mice. A reduced number of plasma cells was also observed in anti-SLAMF6 injected mice (Figures 8D,E), but effector B cell and T cell populations were equivalent in anti-SLAMF6 injected and non-injected mice (Figure 8F and Figures 9D,E). In order to confirm the inhibitory effects of anti-SLAMF6 (330), another anti-SLAMF6 mAb (13G3) was also tested. As expected, a similar inhibitory effect was seen in anti-SLAMF6 injected mice (Figures S4A,B in Supplementary Material).

To address whether the administration of anti-SLAMF6 affects early commitment to antigen specific Th1 cells and GC B cells or late stages of humoral responses, immunized mice were injected with anti-SLAMF6 four days post-immunization, at which point T and B cells are already committed to becoming Th1 and GC B cells.
Wang et al. SLAMF1, SLAMF5, and SLAMF6 are negative regulators

FIGURE 5 | The adoptive transfer of naïve Slamf1+5+6− T or B cells enhanced NP-specific antibody responses after co-transfer of WT B or T cells into Rag-1−/− mice. CD4+ T cells (5 × 10⁶) together with 10 × 10⁶ B cells are isolated from WT and Slamf1+5+6− mice and transferred into Rag-1−/− recipients in the following four combinations of T and B cells: WT CD4+ T and WT B cells, Slamf1+5+6− CD4+ T and Slamf1+5+6− B cells, WT CD4+ T and Slamf1+5+6− B cells, and Slamf1+5+6− CD4+ T and WT B cells. The Rag-1−/− recipients were immunized with 40 μg of NP-OVA in CFA 7 days after the transfer. Mice were sacrificed and NP-specific IgG titers were determined by ELISA day 9 post-immunization. Data are representative of three independent experiments.

FIGURE 6 | A combined ablation of SLAMF1, SLAMF5, and SLAMF6 shows a selective increase in MZ B cells and enhanced TI-2 antibody responses. WT, Slamf1+5+6−, and Slamf1+5+6−/− mice were immunized with 20 μg of NP-Ficoll. NP-specific IgM (A) and IgG3 (B) titers were determined at day 7 by ELISA after serial dilutions of the serum. Results are representative of three independent experiments.

FIGURE 7 | Administration of anti-SLAMF6 antibody has a negative effect on antibody production in protein-immunized WT mice. Mice were immunized with 40 μg NP-OVA in CFA and some were injected with either 250 μg of anti-SLAMF6 (330), anti-SLAMF1 (9D1), anti-SLAMF5 (M5), or mouse Ig isotype control. The mice were sacrificed on day 9 and serum was collected to measure Ig production. (A) NP-specific IgG titers from sera of anti-SLAMF6 injected mice were determined by ELISA. (B) Affinity of NP-specific IgG in immune-sera collected as in (A). (C) NP-specific IgM titers from sera of anti-SLAMF6 injected mice were determined by ELISA. (D) Affinity of NP-specific IgM in immune-sera collected as in (C). (E) NP-specific IgG titers from sera of anti-SLAMF1 injected mice were determined by ELISA. (F) NP-specific IgG titers from sera of anti-SLAMF5 injected or non-injected immunized mice were determined by ELISA. Results are representative of three independent experiments.

(51). Interestingly, the late injection of mice with anti-SLAMF6 did not significantly reduce GC response and antibody production (data not shown). This suggests that the signal initiated by SLAMF6 has efficient inhibition in early Tfh and GC B cell differentiations, but has little effect on late Tfh and GC B cell expansion and antibody production.

To evaluate whether the Fc portion of anti-SLAMF6 influences immune function, anti-SLAMF6 F(ab’)2 fragments were injected into mice along with NP-OVA immunization. Similar to intact anti-SLAMF6, anti-SLAMF6 F(ab’)2 caused a significant decrease in the percentage and number of GC B cells (Figures 10B,C) and Tfh cells (Figures 10D,E). In contrast, an impaired NP-specific antibody production was not observed in the anti-SLAMF6 F(ab’)2 injected mice. To exclude the possibility that NK cells mediate natural cytotoxicity against a variety of immune cells, we examined splenocyte phenotype and levels of...
Wang et al. SLAMF1, SLAMF5, and SLAMF6 are negative regulators of T-dependent antibody responses.

**DISCUSSION**

An important role of SAP in T cell help to B cells has been highlighted in defects in follicular T helper cell differentiation and lack of germinal center development in XLP patients and in virally infected or immunized SAP−/− mice (4, 12, 13, 32, 48, 52). Although SAP has been proven to bind to ITSMs in most SLAMF receptors upon ligand stimulation, how these receptors function in the presence and absence of SAP is poorly understood, particularly in B cells. In this study, we provide in vivo evidence that SLAMF1, SLAMF5, and SLAMF6 synergistically suppress T-dependent and T-independent antibody responses, as SLAMf1+5+6−/− mice, but not SLAMf1+6−/− mice or single SLAMF mutant mice, exhibit a significant enhancement in NP-specific antibody in NK-depleted WT mice following NP-OVA immunization and anti-SLAMF6 injection. Notably, the depletion of NK cells did not impact the capacity of anti-SLAMF6 to suppress antibody production or the development of Tfh cells and GC B cells (data not shown). Thus, severely impaired antibody production by the injection of anti-SLAMF6 is not due to NK cell-mediated ADCC.

Based on the studies using anti-SLAMF6, we next examined the ability of anti-SLAMF1 mAb and anti-SLAMF5 mAb to suppress humoral immune responses in NP-OVA immunized mice. We found that NP-specific antibody production was moderately, but consistently, reduced in anti-SLAMF1 injected mice (Figure 7E). However, anti-SLAMF5 did not suppress antibody production (Figure 7F). In addition, the frequencies of GC B cells and Tfh cells were comparable among the non-injected, anti-SLAMF1, and anti-SLAMF5 injected mice (data not shown). Thus, the results suggest that neither anti-SLAMF1 nor anti-SLAMF5 is alone sufficient to have a significant impact on humoral responses.

Wang et al. SLAMF1, SLAMF5, and SLAMF6 are negative regulators

FIGURE 9 | Administration of anti-SLAMF6 (330) antibody has a negative effect on Tfh cell differentiation in protein-immunized WT mice. Mice were immunized with 40 µg of NP-OVA in CFA and some mice were injected with either 250 µg anti-SLAMF6 (330) or Ig isotype control. The mice were sacrificed on day 9. (A) Representative flow cytometry staining of CD4^+ PD-1^+ CXCR5^+ Tfh cells in the spleens of anti-SLAMF6, isotype, and non-injected immunized mice. (B) Percentage of Tfh cells (CD4^+ PD-1^+ CXCR5^+ ) was determined by flow cytometry in the spleens of anti-SLAMF6, isotype, and non-injected immunized mice. (C) The number of Tfh cells (CD4^+ PD-1^+ CXCR5^+ ) was determined by flow cytometry in the spleens of anti-SLAMF6, isotype, and non-injected immunized mice. (D) Percentage of CD4^+ CD44^hi CD62^lo memory T cells in the spleens of anti-SLAMF6, isotype, and non-injected immunized mice. (E) Percentage of CD4^+ CD44^hi CD69^hi activated T cells in the spleens of anti-SLAMF6, isotype, and non-injected immunized mice. Results are representative of three independent experiments.

Maintaining sustained CD4^+ T cell adhesion to B cells is required for Tfh differentiation and germinal center development, which allows for important signal transfer between T and B cells. SAP-deficient T cells fail to form a stable T-B cell conjugate (41) and thereby severely impaired development of Tfh cells and GC B cells becomes a hallmark in XLP patients and SAP^−/− mice (14, 32, 34, 41). Although most SAP-binding SLAMF receptors are highly expressed on resting and activated T and B cells and implicate a diverse array of lymphocyte functions, including sustained T-B cell conjugates (43, 53), the deficiencies in single SLAMF receptors actually exhibit mild phenotypes. However, in contrast to our current study, Slamf5^−/− mice have previously been shown to have a defect in germinal center development and T-dependent antibody production in protein immunization (43). The reason that the

www.frontiersin.org April 2015 | Volume 6 | Article 158 | 9
same B6 background Slamf$^{+/−}$ mice strains have different phenotypes is not clear. One explanation for this discrepancy is that the presence of selection marker (Neo) could influence neighboring genes in targeted loci (54). Alternatively, it remains possible that the discordant findings could reflect the different environmental conditions of animal facilities.

Because the functional redundancies in SLAMF-mediated signaling have been demonstrated in NKT cell development (45, 46), we speculate that multiple deficiencies in SLAMF receptors may have a strong influence on humoral immune responses that are able to recapitulate most of the phenotypic alterations observed in SAP$^{+/−}$ mice. Surprisingly, in our in vivo studies comparing T-dependent antibody responses, loss of expression of SLAMF1, SLAMF5, and SLAMF6 receptors actually removed inhibitory signaling and resulted in higher antibody responses (Figure 3A). When the antibody responses in mice lacking Slamf$^{1+6}$ were compared to those in WT mice, there was also a consistent increase in NP-specific antibody titer, but the effect was less pronounced than that observed in the combined ablation of SLAMF1, SLAMF5, and SLAMF6. Although some variability in antibody responses between mutant and WT mice occurs, statistical analysis always reached significance. These findings indicate that the homophilic binding of SLAMF1, SLAMF5, and SLAMF6 synergistically transmits inhibitory signaling during humoral immune responses. The dual function of SLAMF receptors was initially reported in NK cell studies. In human NK cells, SLAMF4 predominantly functions as an activating receptor because engagement of SLAMF4 with SLAMF2 mediates NK cell cytotoxicity, cell proliferation, and cytokine secretion. However, in NK cells from XLP patients, the SLAMF2–SLAMF4 interaction fails to activate NK cells, but rather inhibits NK-mediated cytolyis (23). Besides SLAMF4, other SLAMF receptors such as SLAMF3, SLAMF5, and SLAMF6 become inhibitory molecules instead of activating receptors in mouse NK cells lacking SAP, EAT-2A, and EAT-2B (55). Consistent with these findings, a similar inhibitory effect of SLAMF6 on humoral responses and NKT cell development was reported in the context of the absence of SAP (27). Collectively, these observations suggest that most SLAMF receptors can mediate either positive or negative signaling, depending on the expression of SLAMF adaptors, SAP and EAT-2. Given that SAP and EAT-2A/B are not expressed in B cells, the homophilic interactions of SLAMF1, SLAMF5, and SLAMF6 between T and B cells or B and B cells would result in preferential binding to inhibitory signaling molecules (e.g., SHP1) in B cells because of the lack of competition of SAP and EAT-2 for ITSMs of SLAMF receptors. This idea is supported by our adoptive transfer assays, in which B cells from Slamf$^{1+6}$−/− mice led to a further enhancement in antibody responses compared to the transfer of Slamf$^{1+6}$−/− T cells. Furthermore, Slamf$^{1+6}$−/− mice display higher antibody responses in the absence of T cell help when immunized with T-independent antigen NP-Ficoll, which directly indicates that an intrinsic B cell hyperactivation exists in Slamf$^{1+6}$−/− mice.

Although the higher antigen specific antibody production does not accompany enhanced Th and GC B cell responses in the absence of SLAMF1, SLAMF5, and SLAMF6, increased development of plasma cells is consistently observed in NP-OVA immunized Slamf$^{1+6}$−/− mice (Figures 4A–D). The mechanism regulating plasma cell differentiation is only partly understood. Two transcription factors Bcl-6 and Blimp-1 reciprocally modulate differentiation of GC B cells and plasma cells (52). Cytokines and chemokines also provide crucial survival signals to plasma cells (56). Far less is known about SLAMF receptor-mediated signals for plasma cell differentiation and function. However, in our experiments, we provide interesting evidence that SLAMF1, SLAMF5, and SLAMF6 negatively regulate either plasma cell differentiation and/or expansion in humoral immune responses. Further work will assess how SLAMF receptors are involved in plasma cell development at a molecular level.

The interesting finding in this study is that Slamf$^{1+6}$−/− mice exhibit an increased frequency of MZ B cells. A cell-fate decision between follicular B cells and MZ B cells occurs in the transitional (T2) B cell stage, when T2 B cells differentiate into follicular B cells or MZ B cells after integration of BCR signal strength and signaling via other essential signaling molecules (57–59). Like in GC B cells, SLAMF1, SLAMF5, and SLAMF6 are highly expressed in transitional B cells and MZ B cells (ImmGen.org), and therefore, signaling resulting from their homophilic interaction may implicate differentiation, migration, or survival of MZ B cells. Since differentiation of transitional B cells was not altered in Slamf$^{1+6}$−/− mice, signaling initiated by SLAMF1, SLAMF5, and SLAMF6 seems to play a critical role in controlling the development and/or survival of MZ B cells. It has been described that MZ B cells and B1 cells are prime B cell subpopulations responding to T-independent antigens (60, 61). Interestingly, in spite of increased pools of MZ B cells, Slamf$^{1+6}$−/− mice showed enhanced immune responses to the TI-2 Ag NP-Ficoll, but not to the TI-1 Ag NP-LPS. The fact that enhanced TI-antigen response is only limited to TI-2 antigens suggests that Slamf$^{1+6}$−/− MZ B cell intrinsic activity, not number, seems to be more critical in determining the extent of humoral immunity. Thus, these results provide evidence that synergistic activity of SLAMF1, SLAMF5, and SLAMF6 may be implicated in functional activity of MZ B cells.

Complementary approaches with SLAMF receptor-deficient mice and SLAMF-specific antibodies are important for understanding the functions of their immunoregulatory pathways. Recently, SLAMF6 was found not only to constitutively associate with SHP1 in SAP-sufficient cells, but also to co-distribute with the CD3 complex. The ligation of SLAMF6 can reduce CD3ζ phosphorylation (53). Based on these findings, we hypothesize that crosslinking of SLAMF6 by anti-SLAMF6 mAb may cause high phosphorylation in its ITSM. Subsequently, protein tyrosine phosphatases and lipid phosphatases are preferentially recruited to SLAMF6, particularly in SAP and EAT-2 negative B cells. Interestingly, we found that treatment of WT mice with anti-SLAMF6 almost recapitulates the phenotype observed in SAP$^{−/−}$ mice, which showed a marked defect in Th cell and GC B cell formation and reduced antibody production and affinity maturation. Interestingly, a significant defect in humoral response was not observed when mice were treated with anti-SLAMF6 four days after antigen exposure. This further indicates that SLAMF6-mediated inhibitory signals have distinct roles in the early differentiation of Th cells and GC B cells. However, the administration of anti-SLAMF6 F(ab)’2 fragments did not fully suppress NP-specific
antibody production even though the development of Tfh cells and GC B cells was significantly impaired (Figure 10). This difference may be due to a shorter half-life of anti-SLAMF6 F(ab')2, which could prevent it from maintaining sustainable triggering of SLAMF6 receptors during in vivo immune responses. Alternatively, the suppressive effect of anti-SLAMF6 mAb on humoral response might depend on the ability of anti-SLAMF6 Fc to bind to other accessory cells and crosslink the SLAMF6 receptors on Tfh cells and GC B cells. Such crosslinking is necessary for many surface molecules to initiate signaling events. Clearly, further studies are required to determine the contribution of other mechanisms such as complement and non-NK cell-mediated cytotoxicity in suppressing the activity of anti-SLAMF6 mAb. Compared to anti-SLAMF6 mAb, anti-SLAMF1 mAb has a milder, yet consistent, negative effect on antibody production, but anti-SLAMF5 mAb does not show any impact on humoral response. It seems contradictory to the functional redundancy we observed in Slamf6+/- mice because ablation of the Slamf6 gene, but not the Slamf1 gene or Slamf5 gene, can rescue Tfh cell differentiation and antibody production in SAP−/− mice (27, 44). This indicates that SLAMF6 can complement deficiency of either SLAMF1 or SLAMF5 to facilitate inhibitory signaling in the absence of SAP. However, if Slamf1 and Slamf5 double mutations can be introduced into SAP−/− mice, impaired humoral responses may be partially restored. Similarly, the injection of mice with both anti-SLAMF1 mAb and anti-SLAMF5 mAb may also cause some reduction in antibody production. By comparing T-dependent and T-independent antigen responses in Slamf5−/−, Slamf1+ 6−/−, and Slamf1+ 5− 6−/− mice, we demonstrated for first time that SLAMF1, SLAMF5, and SLAMF6 synergistically regulate humoral immune responses. Genetic interruption of SLAMF1, SLAMF5, and SLAMF6 results in enhanced antibody responses to T-dependent and T-independent antigens. In complementary studies, the administration of anti-SLAMF6 mAb further implicates SLAMF6 as a primary inhibitory member of the SLAMF receptors in antibody responses. The studies suggest that the ligation of SLAMF receptors in SAP-negative B cells (Figure 11) may preferentially recruit inhibitory signaling molecules to immunological synapses and control B cell responses during cognate interaction between T and B cells.
