Abstract
This paper introduces a new primitive to serverless language runtimes called `freshen`. With `freshen`, developers or providers specify functionality to perform before a given function executes. This proactive technique allows for overheads associated with serverless functions to be mitigated at execution time, which improves function responsiveness. We show various predictive opportunities exist to run `freshen` within reasonable time windows. A high-level design and implementation are described, along with preliminary results to show the potential benefits of our scheme.

CCS Concepts: • Networks → Cloud computing. • Computer systems organization → Cloud computing.

Keywords: Serverless Computing, Resource Management

1 Introduction
Serverless computing is an emerging paradigm in which cloud providers seamlessly scale developer-provided functions as demands change. Although seemingly simple, serverless functions have been shown to support a wide variety of workloads, from chat bots, video processing, machine learning, HCI, to even general compute. As serverless ecosystems mature, functions will be integrated into a set of larger and larger microservices and will also be relied upon to directly interface with users. As such, the execution latency of serverless functions becomes an important consideration.

However, the simplicity of today’s serverless deployments may increase execution times. Consider a simple function, $\lambda_1$, which downloads a machine learning model from a server, analyzes an input image, and performs additional processing before writing a result to a datastore. Without care, overheads exist. The function must first create a connection to the server hosting the model and then download the model from the server. This behavior could happen anew for subsequent instantiations of $\lambda_1$, even if running sequentially in the same warmed container. When writing the result, another connection must be established before the data is sent. Again, this overhead could reoccur for successive invocations of $\lambda_1$. These per-invocation overheads (e.g., establishing connections, refetching the model, incurring TCP slow start, etc.) quickly add up, which is problematic because many functions have short execution times.

To deal with such issues, developers can utilize runtime reuse. In runtime reuse variables can be runtime-scoped inside the language runtime executing within the container the serverless function runs in. Runtime-scoped variables can be accessed across subsequent serverless function instantiations within a given runtime and container. Revisiting our example, network connections can be reused within a runtime when defined as a runtime-scoped variable to avoid per-instantiation connection overheads.

We argue runtime reuse is insufficient to overcome many of the redundant overheads described earlier. Even with runtime reuse, fetched data could be out-of-date, connections may revert their congestion windows to small initial values or even time out, or application-level state could be stale from the last invocation. To combat these issues, we propose a new primitive called `freshen`, which can be proactively invoked by the serverless infrastructure. A `freshen` hook is implemented in the runtime, allowing developers or providers to establish or warm connections, proactively fetch data, or otherwise perform actions to reduce overheads when the serverless function runs. The `freshen` hook is designed to be run before its corresponding function is instantiated, and we contend this is possible because there are many opportunities to predict a function’s instantiation before it is invoked.

This paper provides motivation and background in Section 2, a preliminary design in Section 3, and potential benefits of `freshen` in Section 4. Related Work is detailed in Section 5. Finally, Section 6 contains discussion and conclusion.

2 Background and Motivation
This section provides background on runtime reuse and highlights scenarios where inefficiencies may remain. Then, we motivate ways to predict function instantiations.

---

1 We use “container” to generally refer to VMs or containers
Serverless runtime reuse While all providers allow runtime reuse, here we explain how an open-source platform, OpenWhisk, enables reuse. OpenWhisk runs functions within Docker containers, listening as a daemon on port 8080. After the container is initialized, the init hook starts the language runtime within the container and also loads the actual function code. When the run hook is invoked, the function is scheduled to run. Thus, the persistent runtime instantiated during init can be thought of as a program that listens for the run hook, executes the function, and returns the result.

Without runtime reuse, variables are scoped for use within a single invocation, termed invocation-scoped. In contrast, runtime-scoped variables can be reused across function instantiations in a given runtime. Common use cases for runtime-scoped variables are Persisting network connections (so connection quotas are not exhausted) and fetching frequently-accessed data during the first function invocation and then storing in the runtime for the container’s lifetime.

Runtime reuse inefficiencies While runtime reuse can increase application efficiency, numerous issues may arise. First, the runtime may not be initialized, such as when a cold start occurs. Studies have shown inefficient container reuse across function invocations, which increases cold start frequency [15]. Other works indicate some serverless infrastructures disallow container sharing between functions, which can increase cold starts when container resources are limited [16]. Second, there may be cases when the runtime is initialized, but data held within the runtime is stale. For example, an object stored within the runtime may need to be re-retrieved because a newer version is available. Network connections may have timed out or have reset their TCP state (e.g., congestion window, round trip times, etc). Linux congestion control reduces the congestion window (CWND) on inactive connections. Last, approaches to reduce connection (re)establishment overheads may not apply. Linux tcp_no_metrics_save allows metrics like RTT and ssthresh to be caged between TCP connections to the same destination, but does not apply to important parameters such as CWND. TCP Fast Open requires sender/receiver support and limits data sent in initial handshakes to small amounts. As a result, even with runtime reuse several inefficiencies remain that can be addressed with proactive calls to freshen.

Regaining efficiency via prediction To alleviate the above concerns, we introduce a freshen hook into the runtime, which can be called before a function is run. The freshen hook allows arbitrary execution of code intended to speed up function execution times. freshen can warm pre-existing network connections, ensure locally-cached items are up-to-date, or even proactively retrieve an object. freshen is most effective when functions are predicted, and this is possible in several cases. First, in function chains (as in Figure 1) explicit knowledge of a function chain could predict impending function invocations within the chain. Function chains are often explicitly provided (as in Orchestration frameworks like AWS Step Functions) or can be derived via tracing or service mesh techniques [9]. To better understand prediction opportunities, we briefly study function chains in Orchestration frameworks. Figure 2 shows a CDF of the number of functions within a single serverless application for Orchestration applications on Azure (data from [12]), compared to the number of functions within a single application over all applications. Orchestration frameworks specifically support function chains, and hence applications utilizing Orchestration frameworks typically consist of more functions: 8 functions in the median Orchestration case versus 2 functions in the median case of all. With a median function runtime of ~700ms [12], prediction opportunities could be as high as ~5.6s in the case of a linear chain (e.g., Figure 1).

Additionally, functions within chains may be triggered by other services, such as storage, pub/sub, or direct invocations. Table 1 shows the median delay, over 20k runs, between invoking a function via the listed service and the actual subsequent triggered function start time in AWS. Cold starts are carefully avoided, and the methodology in [15] is used to obtain overheads by measuring timestamps just before the function trigger and at the start of the triggered-function. The table shows latencies range from 60ms to 1.28s, allowing time to call and execute freshen for the next function within the chain.

3 Design and Implementation This section addresses when freshen could run (Section 3.1), what freshen could do (Section 3.2), and how freshen could be implemented (Section 3.3). Throughout, we refer to an example serverless function λ (Pseudocode 1) to illustrate how freshen could warm a connection and prefetch data. λ fetches data (DataGet) over a connection, performs some calculation on the fetched data and λ’s parameters, writes an output value to an external resource (DataPut), and returns whether the write was successful.
The serverless framework would attempt to run freshen—typically interact with known services such as storage. We posit this is often the case as serverless functions make connections with constant arguments (e.g., constant IP and port). freshen could reestablish the connection. If the connection could not be ascertained connection liveness; if the connection is not alive, freshen could help reduce function latency. If the connection is ephemeral, invocation-scoped connection. In both cases, an ephemeral, invocation-scoped connection to take advantage of runtime reuse and create fresh TCP connections to the same destination. Repetitive invocations can be utilized to anticipate workload characteristics, which could guide the warming function on whether warming is appropriate. The warm_cwnd function can set initial congestion windows or alter congestion windows on longer-running, inactive connections. Since warm_cwnd is implemented as a system call, final determination of actual CWND values, as well as permissions on whether such values can be altered, resides within the provider who is running the underlying host infrastructure.

Other connection-oriented protocols freshen can establish and warm other connection-oriented protocols and protocols that run on top of TCP such as TLS as long as the credentials are constant. However, for TLS establishment and other user-space protocols, the serverless provider would require some knowledge of the libraries used in order to create provider-generated freshen hooks for those resources. Developers who write their own freshen hooks, as detailed in Section 3.3, would have access to such knowledge.

Proactive data fetching Consider the λ in Pseudocode 1: if the data fetched with DataGet is retrieved using constant credentials and resource identifiers, it is possible to prefetch the data before λ is invoked.

Prefetching leads to the concept of a freshen-maintained cache of prefetched data. If the function is invoked frequently within the same runtime and accesses a read-only data resource, it may only be necessary to fetch the data once every n seconds instead of every time the function is run, reducing network traffic. The time-to-live (TTL) of values within the freshen cache could be set by a default value, by freshen configuration values specified by the function developer, or by modifying the DataGet library to configure the TTL value on a per-resource level. In the more general case, associated timestamps or version numbers could be used to determine the freshness of items in the runtime freshen cache, and data could be updated the next time freshen or the serverless function is called.

3.3 Implementation

In the simplest implementation of freshen, the function developer would write freshen for each serverless function that requires optimization. This would provide the most opportunity for customized optimization. freshen may also improve code organization by encapsulating and standardizing maintenance of dynamic resources. As an interesting opportunity for customized optimization.

Pseudocode 1 Sample Serverless Function λ

|   | Runtime Constants: CREDS, ID₁, ID₂ |
|---|----------------------------------|
| 1 | procedure λ(args)               |
| 2 | data := DataGet( CREDS, ID₁ )   |
| 3 | ...                              |
| 4 | result := ...                   |
| 5 | ...                              |
| 6 | ret := DataPut( CREDS, ID₂, result ) |
| 7 | return ret                      |

Figure 3. Predicted and unanticipated timing of freshen
alternative to developers writing \texttt{freshen}, \texttt{freshen} code could be inferred by the serverless framework itself for common resources and for popular serverless languages (e.g., JavaScript, Python).

Code generation would be complex but here we rely on several observations about serverless functions and frameworks to reduce the scope of the problem:

- If \texttt{freshen} were unable to be inferred, the serverless framework could continue unmodified with no major performance loss. Hence, failure to infer is not fatal.
- Source code is available for static analysis for such tasks as identification of read-only data fetched using constant parameters.
- Function code is run repeatedly, so dynamic tracing of functions to identify commonly accessed resources is possible (similar to the tracing used in [6]).
- The latency cost of the network operations \texttt{freshen} seeks to optimize are much slower than CPU speeds so some overhead for \texttt{freshen} inference is permissible.
- Implementing inference only for libraries used to access other cloud services offered by the serverless provider has the potential to lower latency for a majority of functions without having to infer \texttt{freshen} behavior for unknown resources.

One option for implementing \texttt{freshen} for scripting languages is to use added runtime-scoped state and dynamically-inserted wrapper functions. The purpose of the runtime-scoped state is to track and coordinate \texttt{freshen} resources between the \texttt{freshen} call and the actual function invocation. The purpose of the dynamically-inserted wrappers is to intercept access to freshened resources. We will illustrate a simplified example of what an inferred \texttt{freshen} could resemble for the $\lambda$ in Pseudocode 1.

The runtime-scoped state would minimally be a collection of ordered \texttt{freshen} resources. A \texttt{freshen resource} is any object or resource that the \texttt{freshen} code may interact with, such as a socket or a data object. In our example, the \texttt{freshen} resources are kept in an ordered runtime-scoped list called \texttt{fr_state}. In Pseudocode 1, the \texttt{DataGet} operation which \texttt{freshen} can fetch or prefetch, will be assigned index 0 since it is the first resource accessed by $\lambda$, \texttt{DataPut}, which \texttt{freshen} can warm, is assigned index 1. Each entry in \texttt{fr_state} could contain a variety of metadata, such as a \texttt{state} (e.g., running, finished, etc.), a \texttt{result} (e.g., the prefetched data), a \texttt{TTL} for the result, and a \texttt{timestamp} recording the last time that entry was freshened. For simplicity, we only consider \texttt{state} and \texttt{result} in the following pseudocode.

Pseudocode 2 illustrates an example \texttt{freshen} function for $\lambda$. As mentioned, \texttt{DataGet} is assigned to index 0 and \texttt{DataPut} is assigned to index 1. The states \texttt{running} and \texttt{finished} surround the \texttt{DataPut} and \texttt{DataGet} calls of \texttt{freshen}, and are used to coordinate the execution of \texttt{freshen} with the execution of $\lambda$. Pseudocode 3 is the annotated version of Pseudocode 1. The function wrappers appear at lines 3 and 7. The function wrappers used are \texttt{FrFetch} (for \texttt{freshen fetch}) and \texttt{FrWarm} (for \texttt{freshen warm}).

Pseudocode 2 Freshen Function for $\lambda$

```
1: Runtime State: fr_state
2: procedure Freshen
3:  fr_state[0] := running
4:  fr_state[0].result := DataGet( CREDS, ID_1 )
5:  fr_state[0] := finished
6:  fr_state[1] := running
7:  DataPut.warm( CREDS )
8:  fr_state[1] := finished
9:  return
```

Pseudocode 3 Annotated Sample Serverless Function

```
1: Runtime Constants: CREDS, ID_1, ID_2
2: procedure $\lambda$(args)
3:  data := FrFetch( 0, DataGet( CREDS, ID_1 ) )
4:  ...
5:  result := ...
6:  ...
7:  ret := FrWarm( 1, DataPut( CREDS, ID_2, result ) )
8:  return ret
```

Psuedocode 4 and 5 are the implementations of those wrappers. The main function of each wrapper is to synchronize \texttt{freshen} actions with $\lambda$’s use of that resource. If the resource has already been freshened, the wrapper returns either the prefetched data (line 4 in Pseudocode 4) or nothing where \texttt{freshen}’s only job is to warm the resource (line 4 in Pseudocode 5). In Pseudocode 5 it is assumed that there is already some knowledge of how to warm \texttt{DataPut} (e.g., the call to \texttt{DataPut.warm}() in line 7 of Pseudocode 2). If \texttt{freshen} has started freshening the resource (indicated by the state \texttt{running}), both wrapper functions wait for the \texttt{freshen} thread to finish before returning (line 6 in Pseudocode 4 and line 6 in Pseudocode 5). Finally, if \texttt{freshen} either did not run or is executing slower than $\lambda$, the wrapper can perform the freshen action itself (line 10 in Pseudocode 4 and line 10 in Pseudocode 5). Not included for brevity in Pseudocode 2 are the checks to see if the resources have already been freshened by wrapper functions invoked by $\lambda$.

Billing and accounting Since \texttt{freshen} runs to benefit the serverless application, the serverless application owner should pay for it. However, as outlined above, \texttt{freshen} would ideally be triggered based on predictions by the serverless framework. What happens if the platform mispredicts a function call? Confidence in prediction could be used to dictate if \texttt{freshen} is called or not. Metrics kept inside a container, or communicated to the serverless global scheduling entity,
4 Evaluation

This section explores the advantages a \texttt{freshen} hook could provide. First, the benefits of file caching are evaluated. Then, improvements from connection warming are illustrated.

Preempting abuse and misconfiguration A danger if the application developer were allowed to implement their own \texttt{freshen} is that the application developer would try to implement their entire function in \texttt{freshen}. This is undesirable and unprofitable for the developer for several reasons: \texttt{freshen} has no access to function arguments, the application developer is paying for the compute and network resources regardless, and the application would have to handle spurious invocations (mispredictions) gracefully.

4 Related Work

Much research reduces cold start costs. These works are partitioned into two categories: those that are compatible
with existing serverless architectures and those that propose significant changes to serverless architecture. Of those compatible with existing serverless architectures, techniques include cold start avoidance (runtime reuse), light-weight isolation mechanisms [11], intelligent host scheduling [14], and caching of resources ranging from libraries [11] to virtual Ethernet infrastructure [10]. Our work has a different focus, optimizing warm starts, but is compatible with these techniques. Catalyzer [3] snapshots static application state; our work addresses dynamic state and is complementary. AWS Lambda Extensions address static and dynamic resources, but do not provide opportunities for prediction [17]. Works that focus on avoiding cold starts by predicting function execution [5, 12, 14] motivate our design because freshen would be most effective when function invocations are predicted. Of works that propose fundamental changes to serverless architecture such as running more than one function within the same isolation context [1] or adding distributed application state and/or message passing abilities between serverless functions [1, 13], the motivation for freshen remains but implementation strategies would vary.

Last, Containerless [6] avoids the cost of strong isolation mechanisms by transforming JavaScript serverless functions into Rust via dynamic tracing. Their dynamic tracing design, as well as analysis of the resulting traces, could help inform how freshen could be inferred by providers.

6 Discussion and Conclusion

Discussion There exists many opportunities for future work. First, the system should be fully deployed and thoroughly evaluated. Quantifying how freshen affects variability in application behavior would be an important component of this evaluation. Prediction success must be additionally quantified, especially in the case of non-deterministic function chains. In addition, the framework must be analyzed for misuse and resource limiting [8] and hardened as necessary. Impact on developer burden, or the extent to which providers can automatically generate freshen must also be further studied. Integration with microservices or other primitives [2] is interesting future work. Finally, integrating freshen into serverless architectures that provide different isolation scopes is an additional area for future study (e.g., Azure offers chain-level isolation).

Conclusion This paper proposes a new primitive to serverless language runtimes called freshen. With freshen, developers or service providers specify functionality to complete before a given function executes. This proactive framework allows for overheads associated with serverless functions to be mitigated at execution time, which improves function responsiveness. We argue predictive opportunities exist to enable freshen to be run with ample time. A high-level design and implementation are presented, along with preliminary results to show potential benefits of the scheme.
