Abstract. The aim of this study is to determine the stress-strain behavior of basalt fibred concrete experimentally. Cylinders of standard size 150 x 300 mm are cast with and without basalt fibres and tested in uni-axial compression under strain control as per IS: 516-1999 to understand the stress-strain behavior of basalt fibred concrete. After developing empirical equations for stress-strain curves of basalt fibred concrete, theoretical values of stresses are calculated at different values of strains in concrete based on the developed empirical equations as given above and theoretical stress-strain curves are plotted. These theoretical stress-strain curves are compared with experimental stress-strain curves and found that, theoretical stress-strain curves have shown good correlation with experimental stress-strain curves for all concrete mixes.

1 Introduction

The purpose of this experiment is to examine the stress-strain behaviour of basalt fibred concrete. To study the stress-strain behaviour of basalt fibred concrete, cylinders of standard dimension 150 x 300 mm are cast with and without basalt fibres and tested in uni-axial compression under strain control as per IS: 516-1999. The average stress-strain curve for M30 grade basalt fibred concrete is drawn from the values of stresses and strains, using the average values of the three cylinders' findings.

2 Mathematical Modeling for Stress-Strain Behaviour

Following the experimental determination of the stress-strain behaviour of basalt fibred concrete, an attempt was made to derive the analytical stress-strain curves for the aforementioned mix. A variety of empirical equations have been presented to characterise uni-axial stress-strain behaviour of ordinary concrete, however most of them can only be utilised for the climbing section of the curve. Carriera and Chu expanded Popovics' empirical equation, which covers both ascending and descending sections of the full stress-strain curve, presented in 1985. The stress-strain diagram is given in a non-dimensional manner along both axes to compare the behaviour of basalt fibred concrete. Divide the stress at any level by peak stress and the strain at any level by peak strain to get the above form. As a result, at peak stress, all stress-strain curves will have the same point (1,1). The behaviour may be expressed as a generic behaviour by non-dimensionalizing the stresses and strains as shown above. The stress-strain curves for basalt fibred concrete produced experimentally were normalised as described above, and normalised stress-strain values were computed.

3 Proposed Model for Stress-Strain Behaviour

* Corresponding author: hashamis61@gmail.com
Theoretical stresses have been calculated using proposed empirical equations for basalt fibred concrete which are derived from Seanz’s model in the form of

\[ Y = (AX)/(1+BX^2) \]

where \( Y \) is normalized stress, \( X \) is normalized strain, \( A \) and \( B \) are constants for normalized stress-strain curve.

**Calculation of \( T \) and \( f_{ck} \)**

To get the entire stress-strain behaviour of recycled aggregate concrete, many equations in various forms were tested. Seanz’s model was used to produce normalised stress-strain curves using analytical equations from a variety of potential trials. The developed equation is in the form of

\[ Y = \frac{AX}{(1+BX^2)} \]

Where \( X \) - Normalised strain, \( Y \) - Normalised stress

\( A, B \) are constants for ascending portion and \( C, D \) are constants for descending portion for normalized stress-strain curves

To get the entire stress-strain behaviour of recycled aggregate concrete, many equations in various forms were tested. Seanz’s model was used to produce normalised stress-strain curves using analytical equations from a variety of potential trials. The suggested equation for basalt fibred concrete is

\[ Y = \frac{AX}{(1+BX^2)} \]

Let \( A_{σ_0}/C_0 = A^1 \) and \( B/C_0^2 = B^2 \)

Substituting

\[ \sigma = A \frac{C}{C_0} \]

\( \sigma \) - is the stress corresponding to any strain \( C \)

Where \( C_0 \) is the strain corresponding to peak stress \( σ_0 \)

**5 Theoretical Stress-Strain behaviour**

Empirical equations for stress-strain behaviour of concrete mixes were established after experimentally getting the stress-strain behaviour of basalt fibred concrete. Stresses are computed using empirical formulae, and stress-strain curves are shown using theoretical stress values. The experimental stress-strain curves are displayed after generating empirical equations for stress-strain curves of basalt fibred concrete. These theoretical stress-strain curves were compared to experimental stress-strain curves, and it was discovered that for all concrete mixes, theoretical stress-strain curves had a strong agreement with experimental stress-strain curves.

The constants in the ascending section of the normalised stress-strain curve are determined by boundary conditions I and ii, whereas the constants in the descending portion of the curve are determined by boundary conditions ii, iii, and iv.

Constants for basalt fibred concrete are derived using the boundary conditions in non-dimensional stress-strain curves, and equations are built from there. Finally, analytical equations that describe the entire stress-strain behaviour are created. The suggested equation for basalt fibred concrete is

\[ Y = \frac{AX}{(1+BX^2)} \]

Further research will be conducted using these normalised stress-strain curves. The suggested empirical equations may be utilised to analyse the flexural behaviour of concrete structural components as a stress block.
be found by dividing the stress at any level by peak stress and the strain at any level by peak strain. The experimentally acquired stress-strain curves for all concrete mixes were normalised, and normalised stress-strain values were computed.

To get the entire stress-strain behaviour of concrete mixtures including basalt fibres, several equations were tested.

### 6 Conclusions

From the observations made from stress-strain curves, the following conclusions are drawn:

1. When compared to regular concrete without fibres, optimally basalt fibred concrete has exhibited better stress values for the same strain levels.
2. Because the degree of internal micro cracking in basalt fibred concrete has decreased, the strain at peak stress is somewhat higher, and the slope of the falling section is steeper.
3. The model suggested for predicting stress-strain behaviour founds to be reasonable as the experimental values are correlating with the theoretical values validating the model developed.
4. For similar strains in basalt fibre concrete and normal concrete, peak stress in basalt fibre concrete is more indicating the ultimate load carrying capacity.
5. For similar stresses in basalt fibre concrete and normal concrete, the strains are improved in concrete due to inclusion of basalt fibres.
