ABSTRACT
The problem of coupled heat and mass transfer by free convection of a chemically reacting viscous incompressible and electrically conducting fluid confined in a vertical channel bounded by wavy wall and flat wall in the presence of diffusion-thermo (Dufour), thermal-diffusion (Soret) and internal heat source or sink is studied. The walls are maintained at constant but different temperatures and species concentrations. A uniform magnetic field \( \beta_0 \) is acting transversely to the walls which are assumed to be electrically non-conducting. The dimensionless governing equations are perturbed into mean part (zeroth-order) and perturbed part (first-order), using amplitude as a perturbation parameter. The first-order quantities are obtained by long wave approximation. The resulting set of coupled ordinary differential equations are solved numerically using the Adomian decomposition method. Some of the results indicating the influence of various parameters on the zeroth-order and first-order fluid flow, heat and mass transfer characteristics are presented graphically.

1. Introduction
Recently, there has been some renewed attentions in the study of free convective heat and mass transfer in fluid flow through a wavy or irregular channel. This is because the analysis of such flows find applications in various industrial and engineering problems such as nuclear reactor, heat ex-changers, transpiration cooling of re-entry vehicles and rocket boosters, film vapourization in combustion chambers and cross-hatching on ablative surfaces [1,2]. Additional significant applications include the use of rough (wavy) walls in medical apparatus to increase the mass transfer in blood (blood oxygenator). Rough surfaces are often used as flow passages in several applications for controlling the rate of heat transfer, cooling of electronic components and the designing of ventilating-heating building [3,4].

Some of the mentioned studies include, for example, the work of Vajraelu and Sastri [1] who examined the influence of waving of one of the walls on the flow and heat transfer characteristics of an incompressible viscous fluid confined between two long vertical walls. Fasogbon [2] discussed analytically, the studies of heat and mass transfer by free convection in a two-dimensional irregular channel. Recently, the effects of chemical reaction and heat source on two-dimensional free convection magneto-hydrodynamics (MHD) flow in an irregular channel with porous medium were investigated by Davika et al. [3]. Most recently, two-dimensional heat transfer of a free convection MHD flow with radiation and temperature-dependent heat source of a viscous incompressible fluid in a porous medium within a wavy channel were discussed by Dada and Disu [4]. Fasogbon and Omolehin [5] examined the radiation effect on natural convection in an irregular channel. Abubakar [6] studied the effect of the wall slip on a laminar two-dimensional free convective flow of fluid confined between an irregular wall and a flat wall. He discovered that increase in the slip parameter at the flat wall leads to a decrease in fluid velocity. Kumar [7] studied two-dimensional heat transfer of a free convective MHD flow with radiation and temperature-dependent heat source of a viscous incompressible fluid in a vertical irregular channel.

Meanwhile, it is well known that for a simultaneous occurrence of heat and mass transfer in a moving fluid, the relationships between the driven potential and the corresponding fluxes are of important. Also it is noticed that the energy flux (rate of energy transfer per unit area) and mass flux (rate of mass flow per unit area) can be generated by temperature gradients as well as composition gradients. The energy caused or generated by composition gradients is known as Dufour or diffusion-thermo effect and is considered useful in isotope separation. The mass flux created or generated by temperature gradients is known as Soret or thermal-diffusion effect which is consid-
ered useful in mixture of gases with very light molecular weight (hydrogen–helium) and medium molecular weight (nitrogen–air) Kafoussias and William [8]. In view of the technological important applications of Soret and Dufour effects in sciences and engineering, these terms are considered in energy and concentration equations respectively in the present work.

In view of these applications, Gbadeyan et al. [9] examined the effects of thermal-diffusion and diffusion-thermo on combined heat and mass transfer on mixed convective boundary layer flow over a stretching vertical surface in a porous medium filled with a viscoelastic fluid in the presence of magnetic field. Makinde and Olanrewaju [10] carried out the study of an unstable mixed convection with Soret and Dufour effects past a porous plate moving through a binary mixture of chemically reacting fluid. Olanrewaju and Gbadeyan [11] analysed a mathematical model in order to study the effect of Soret, Dufour, chemical reaction, thermal radiation and volumetric heat generation/absorption on mixed convection stagnation point flow on an isothermal vertical plate in a porous media. Alam et al. [12] studied Dufour and Soret effects on steady free convection and mass transfer flow past a semi-infinite vertical porous plate in a porous medium. Olanrewaju et al. [13] analysed the influence of chemical reaction, thermal radiation, thermal-diffusion, diffusion-thermo on hydromagnetic free convection with heat and mass transfer past a vertical plate with suction/injection. Also, Olanrewaju and Makinde [14] investigated free convective heat and mass transfer of an incompressible electrically conducting fluid past a moving vertical plate in the presence of suction and injection with thermal-diffusion (Soret) and diffusion-thermo (Dufour) effects.

MHD (magneto fluid dynamics or hydromagnetics) is the study of the dynamics of electrically conducting fluids. Example of such fluid include plasma, liquid metal and salt water or electrolytes. The fundamental concept behind MHD is that magnetic field can induce electric currents in a moving conductive fluid, which in turn creates forces on the fluid and also changes the magnetic field itself, this has led to extensive studies of MHD fluid flow. For example, Das and Ahmed [15] studied the problem of free convective MHD flow and heat transfer in a viscous incompressible fluid confined between a long wavy wall and a parallel flat wall. Disu and Dada [16] examined two-dimensional heat transfer of a free convective-radiative MHD flows with variable viscosity and heat source of a viscous incompressible fluid in a porous medium between two vertical wavy walls.

Also chemical reaction is a process that leads to transformation of one set of chemical substances to another. The chemical reactions are central to chemical engineering where they are used for synthesis of new compound from natural raw materials such as petroleum, mineral ores and thermite reaction to generate light and heat in pyrotechnics and welding. The presence of a foreign mass in air or water causes some kind of chemical reaction. Some foreign mass may be present either naturally or mixed with air or water. It is enormous practical consequence to engineers and scientists, because of the study of heat and mass transfer with chemical reaction is almost universal occurrence in many branches of science and engineering (Loganathan et al. [17]). In this article [17], the authors examined the influence of chemical reaction on unsteady free convective and mass transfer flow past a vertical plate with variable viscous and thermal conductivity. Also, the natural convective power-law fluid flow past a vertical plate embedded in a non-darcian porous medium in the presence of a homogeneous chemical reaction is studied in Chamka et al. [18].

Furthermore, heat transfer is a process by which internal energy from one substance transfers to another and mass transfer is the transport of a substance (mass) in liquid or gaseous media. Heat and mass transfer occur simultaneously in many processes, such as drying evaporation at the surface of the wet body, energy transfer in a wet cooling tower, flow in a desert cooler, polymer production and food processing. In view of these applications, therefore, it is of interest to combine heat and mass transfer with chemical reaction, MHD, Dufour and Soret effects because of their applications in many processes occurring both in nature and industries involving fluid flow.

However, to the best of our knowledge, no work has been done on the problem of free convection heat and mass transfer in a viscous fluid flowing over a wavy wall or confined between two walls one or both of which are wavy, involving chemical reaction in the presence of both Soret and Dufour. Thus, there is a definite need for the investigation of such a problem. This fact along with the potential application of this problem represent the significance of the present work. Hence, the goal of the present work is, therefore, to investigate the combined effects of Soret and Dufour on heat and mass transfer in chemically reacting MHD flow through a rough (wavy) channel. The non-dimensional coupled boundary value problem governing the fluid flow was perturbed and the resulting zeroth- and first-order boundary value problem were solved using the Adomian decomposition method with MAPLE 14 software.

2. Formulation of the research problem

The channel considered is made up of a finitely long irregular (wavy) wall at one end and a flat wall at the other. The $X'$-axis is taken to be vertically upward and parallel to the flat wall in the direction of buoyancy, while $Y'$-axis is perpendicular to the $X'$-axis in such a way that the position of irregular wall is represented by $Y' = e^* \cos kX'$, $|e^*| < 1$, and that of the flat wall is represented by $Y' = d$ (Figure 1).
In formulating this problem, the following assumptions are made:

(I) The irregular and flat walls are at constant temperatures \( T_w \) and \( T_s \), respectively and constant concentrations \( C_w \) and \( C_1 \), respectively.

(II) All fluid properties are constant except the density in the buoyancy force term.

(III) The viscous and magnetic dissipation are neglected in the energy equation and that work done by pressure are sufficiently small in comparison with both the flow by conduction, wall temperatures and wall concentrations.

(IV) The flow is laminar, steady, hydromagnetic and two-dimensional.

(V) The volumetric heat source/sink term in energy equation is constant and the small amplitude wall roughness is characterized by a certain wave-length \( \lambda = (2\pi /k) \), where \( k \) is the wave number.

(VI) The thermal-diffusion and diffusion-thermo are of substantial magnitudes such that they cannot be neglected.

(VII) The electric field is assumed to be zero, the induced magnetic field is negligible compared to the applied magnetic field, since the magnetic Reynolds number is very small for most fluid used in industrial application.

(VIII) The reaction is of first-order, the rate of reaction is directional proportional to concentration differences.

Based on these assumptions with the usual Boussinesq approximation, the governing equations of steady two-dimensional heat and mass transfer are made up of the following dimensional continuity, momentum, energy and species equations.

Continuity equation
\[
\frac{\partial U'}{\partial X'} + \frac{\partial V'}{\partial Y'} = 0. \tag{1}
\]

Momentum equations
\[
\rho \left( \frac{U'}{\partial X'} + V' \frac{\partial U'}{\partial Y'} \right) = - \frac{\partial P'}{\partial X'} + \mu \left( \frac{\partial^2 U'}{\partial X'^2} + \frac{\partial^2 U'}{\partial Y'^2} \right) \tag{2}
\]

Energy equation
\[
\rho C_p \left( \frac{U'}{\partial X'} + V' \frac{\partial T'}{\partial Y'} \right) = K \left( \frac{\partial^2 T'}{\partial X'^2} + \frac{\partial^2 T'}{\partial Y'^2} \right) + Q + \rho D_m K_f \left( \frac{\partial^2 C'}{\partial X'^2} + \frac{\partial^2 C'}{\partial Y'^2} \right), \tag{3}
\]

and Concentration equation
\[
\left( \frac{U'}{\partial X'} + V' \frac{\partial C'}{\partial Y'} \right) = D_m \left( \frac{\partial^2 C'}{\partial X'^2} + \frac{\partial^2 C'}{\partial Y'^2} \right) + \frac{D_m K_f}{T_m} \left( \frac{\partial^2 T'}{\partial X'^2} + \frac{\partial^2 T'}{\partial Y'^2} \right) - k_1 (C' - C_s). \tag{4}
\]

The corresponding boundary conditions of the problem are taken as
\[
U' = 0, \quad V' = 0, \quad T' = T_{w}, \quad C' = C_w \text{ on } Y' = \epsilon^* \cos kX', \tag{5}
\]
\[
U' = 0, \quad V' = 0, \quad T' = T_s, \quad C' = C_1 \text{ on } Y' = d. \tag{6}
\]

Furthermore, it is remarked at this juncture, that for free convection flows, the associated velocities are considerably small while the presence of viscous energy dissipation term usually calls for high-speed flows. Hence, the above assumption that the influence of the viscous dissipation term in the energy equation may be considered negligible is practically reasonable, on the other hand, the inclusion of Joule heating’s (magnetic dissipation) effect is of importance for fluid whose medium possesses very high electrical conductivity. However, fluid whose medium is of low electrical conductivity are considered in this problem. Hence, the effect of the magnetic dissipation may be safely regarded negligible. Similar argument hold for the above assumptions.

The following non-dimensional variables
\[
(x, y) = \frac{1}{d} (X', Y'), \quad (u, v) = \frac{d}{U} (U', V'),
\]
\[
\lambda = kd, \quad \epsilon = \epsilon^* \cos kX', \quad p' = \frac{\rho d^2}{\nu^2}, \quad \rho s = \frac{\rho d^2}{\nu v^2}, \quad \theta = \frac{T - T_s}{T_w - T_s}, \quad T_s \neq T_w,
\]
\[
\epsilon = \frac{C - C_s}{C_w - C_s}, \quad C_s' \neq C_w
\]

were introduced into equations (1)–(7) to obtain the following non-dimensional equations.

\[
(x, y) = \frac{1}{d} (X', Y'), \quad (u, v) = \frac{d}{U} (U', V'),
\]
\[
\lambda = kd, \quad \epsilon = \epsilon^* \cos kX', \quad p' = \frac{\rho d^2}{\nu^2}, \quad \rho s = \frac{\rho d^2}{\nu v^2}, \quad \theta = \frac{T - T_s}{T_w - T_s}, \quad T_s \neq T_w,
\]
\[
\epsilon = \frac{C - C_s}{C_w - C_s}, \quad C_s' \neq C_w
\]
Continuity equation
\[ \frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} = 0. \] (9)

Momentum equations
\[ \frac{\partial u}{\partial x} + v \frac{\partial u}{\partial y} = - \frac{\partial p}{\partial x} + \frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} - g \frac{x d^3}{\nu^2} - Hu, \] (10)
\[ \frac{\partial v}{\partial x} + u \frac{\partial v}{\partial y} = - \frac{\partial p}{\partial y} + \frac{\partial^2 v}{\partial x^2} + \frac{\partial^2 v}{\partial y^2}. \] (11)

Energy equation
\[ P_f \left( u \frac{\partial \theta}{\partial x} + v \frac{\partial \theta}{\partial y} \right) = \frac{\partial^2 \theta}{\partial x^2} + \frac{\partial^2 \theta}{\partial y^2} + \frac{\partial^2 \epsilon}{\partial x^2} + \frac{\partial^2 \epsilon}{\partial y^2} + P_f D_u \left( \frac{\partial^2 \epsilon}{\partial x^2} + \frac{\partial^2 \epsilon}{\partial y^2} \right) + \alpha, \] (12)

and Concentration equation
\[ S_c \left( u \frac{\partial c}{\partial x} + v \frac{\partial c}{\partial y} \right) \approx \frac{\partial^2 c}{\partial x^2} + \frac{\partial^2 c}{\partial y^2} + \frac{\partial^2 \epsilon c}{\partial x^2} + \frac{\partial^2 \epsilon c}{\partial y^2} - S_c \gamma c. \] (13)

The corresponding boundary conditions are
\[ u = v = 0, \quad \theta = c = 1 \text{ on } y = \epsilon \cos \lambda x, \] (14)
\[ u = v = 0, \quad \theta = m_1, \quad c = m_2 \text{ on } y = 1, \] (15)

In the static fluid (subscripts), we have
\[ 0 = \frac{\partial p_s}{\partial x} - \rho \frac{g_x d^3}{\nu^2}, \] (16)

so that equation (10) becomes
\[ \frac{\partial u}{\partial x} + v \frac{\partial u}{\partial y} = - \frac{\partial (p - p_s)}{\partial x} + \frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} + G_1 \theta_1 + G_2 c_1 - Hu, \] (17)

where \( \rho_s = \rho \left( 1 + \beta_T (T_w - T_s) \theta + \beta_c (C_w - C_i) c \right) \) is the well-known Boussinesq approximation.

All the physical variables are as defined in the nomenclature.

### 3. Method of solution

The irregularity of the wall is assumed small, hence it is appropriate to seek a perturbation solution for small \( \epsilon \). The limit \( \epsilon = 0 \) is, of course, the limit of a smooth flat wall, for which the solution is well known. Thus we take the flow field variables, velocity, pressure, temperature and concentration as
\[ u(x, y) = u_0(y) + \epsilon u_1(x, y), \quad v(x, y) = \epsilon v_1(x, y), \]
\[ p(x, y) = p_0(x) + \epsilon p_1(x, y), \]
\[ \theta(x, y) = \theta_0(y) + \epsilon \theta_1(x, y), \]
\[ c(x, y) = c_0(y) + \epsilon c_1(x, y). \] (19)

Putting equation (19) into equations (9)–(13), we obtained zeroth- and first-order set of equations where the perturbed quantities \( u_1, v_1, \theta_1 \) and \( c_1 \) are small compared with mean or the zeroth-order quantities \( u_0, \theta_0 \) and \( c_0 \).

For zeroth-order (by equating the coefficients of \( \epsilon^0 \)), we have
\[ \frac{d^2 u_0}{dy^2} + G_1 \theta_0 + G_2 c_0 - H u_0 = c_p, \] (20)
\[ \frac{d^2 \theta_0}{dy^2} + P_f D_u \frac{d^2 \epsilon_0}{dy^2} = -\alpha, \] (21)
\[ \frac{d^2 c_0}{dy^2} + S_c \gamma c_0 \frac{d^2 \epsilon_0}{dy^2} - S_c \gamma c_0 = 0, \] (22)

with the following boundary conditions
\[ u_0 = 0, \quad \theta_0 = c_0 = 1 \text{ on } y = 0, \]
\[ u_0 = 0, \quad \theta_0 = m_1, \quad c_0 = m_2 \text{ on } y = 1, \] (23)

where \( c_p = (\partial (p_0 - p_1)/\partial x) \), and is taken to be equal to zero, following [1,2].

And for first-order (by equating coefficients of \( \epsilon^1 \)), we have
\[ \frac{\partial u_1}{\partial x} + \frac{\partial v_1}{\partial y} = 0, \] (24)
\[ \frac{\partial u_0}{\partial x} + \frac{\partial u_1}{\partial y} = - \frac{\partial p_1}{\partial x} + \frac{\partial^2 u_1}{\partial x^2} + \frac{\partial^2 u_1}{\partial y^2} + G_1 \theta_1 + G_2 c_1 - Hu_1, \] (25)
\[ \frac{\partial v_1}{\partial x} = - \frac{\partial p_1}{\partial y} + \frac{\partial^2 v_1}{\partial x^2} + \frac{\partial^2 v_1}{\partial y^2}, \] (26)
\[ P_f \left( \frac{\partial \theta_1}{\partial x} + \frac{\partial v_1}{\partial y} \right) = \frac{\partial^2 \theta_1}{\partial x^2} + \frac{\partial^2 \theta_1}{\partial y^2} + P_f D_u \left( \frac{\partial^2 c_1}{\partial x^2} + \frac{\partial^2 c_1}{\partial y^2} \right), \] (27)
\[ S_c \left( u_0 \frac{\partial c_1}{\partial x} + v_1 \frac{dc_0}{dy} \right) = \frac{\partial^2 c_1}{\partial x^2} + \frac{\partial^2 c_1}{\partial y^2} + S_c \left( \frac{\partial^2 \psi_1}{\partial x^2} + \frac{\partial^2 \psi_1}{\partial y^2} \right) = S_c \gamma c_1, \]  

with the boundary conditions

\[
\begin{align*}
\psi_1 = -u_0, & \quad v_1 = 0, & \quad \theta_1 = -\theta, & \quad c_1 = -c_0 \text{ on } y = 0, \\
u_1 &= 0, & \quad v_1 = 0, & \quad \theta_1 = 0, & \quad c_1 = 0 \text{ on } y = 1,
\end{align*}
\]  

where prime denotes differentiation with respect to \( Y \). To solve equations (24)–(29), we introduce stream function \( \psi_1(x,y) \) defined as

\[ u_1 = -\frac{\partial \psi_1(x,y)}{\partial y}, \quad v_1 = \frac{\partial \psi_1(x,y)}{\partial x}. \]  

So that (24) is satisfied and eliminating the dimensionless pressure \( p_1 \), we obtain

\[ \frac{\partial^4 \psi_1}{\partial y^4} + \frac{\partial^4 \psi_1}{\partial x^4} + 2 \frac{\partial^2 \psi_1}{\partial x^2 \partial y^2} - u_0 \frac{\partial^3 \psi_1}{\partial x \partial y^3} - u_0 \frac{\partial^2 \psi_1}{\partial y^3} + \frac{d^2 u_0}{dy^2} \frac{\partial^2 \psi_1}{\partial x \partial y} - \frac{\partial^2 \psi_1}{\partial x \partial y} = G_1 \frac{\partial \psi_1}{\partial y} + G_2 \frac{\partial c_1}{\partial y}, \]  

(31)

\[ P_r \left( u_0 \frac{\partial \psi_1}{\partial x} + \frac{d c_0}{dy} \frac{\partial \psi_1}{\partial x} \right) = \frac{\partial^2 \psi_1}{\partial x^2} + \frac{\partial^2 \psi_1}{\partial y^2} + \frac{d^2 u_0}{dy^2} \frac{\partial^2 \psi_1}{\partial x \partial y} - \frac{\partial^2 \psi_1}{\partial x \partial y} \right) = G_1 \frac{\partial \psi_1}{\partial y} + G_2 \frac{\partial c_1}{\partial y} \]  

(32)

\[ S_c \left( u_0 \frac{\partial c_1}{\partial x} + v_1 \frac{dc_0}{dy} \right) = \frac{\partial^2 c_1}{\partial x^2} + \frac{\partial^2 c_1}{\partial y^2} + S_c \left( \frac{\partial^2 \psi_1}{\partial x^2} + \frac{\partial^2 \psi_1}{\partial y^2} \right) - S_c \gamma c_1, \]  

(33)

while the corresponding boundary conditions become

\[ \frac{\partial \psi_1}{\partial y} = u_0, \quad \frac{\partial \psi_1}{\partial x} = 0, \quad \theta_1 = -\theta, \quad c_1 = -c_0 \text{ on } y = 0, \]  

\[ \frac{\partial \psi_1}{\partial x} = 0, \quad \frac{\partial \psi_1}{\partial y} = 0, \quad \theta_1 = 0, \quad c_1 = 0 \text{ on } y = 1. \]  

Due to the nature of the wall, we assume wave-like solutions of the form

\[ \psi_1(x,y) = e^{i \beta x} \psi_1(\lambda y), \quad \theta_1(x,y) = e^{i \beta x} \phi(\lambda y), \quad c_1(x,y) = e^{i \beta x} \psi(\lambda y), \]  

(35)

perturbation series expansion for small wavelength in which terms of exponential order arise from which we deduce that

\[ u_1(x,y) = -e^{i \beta x} \psi(\lambda y), \quad v_1(x,y) = e^{i \beta x} \psi(\lambda y), \]  

where \( i \) is the complex unit (see [2]).

Substituting (35) into (31)–(34), we have

\[ \psi'' - H \psi'' = i \lambda \left( u_0 \psi'' - \lambda^2 u_0 \psi - u_0' \psi \right) + \lambda^2 \left( 2 \psi'' - \lambda^2 \psi \right) + G_1 \phi' + G_2 \phi', \]

(36)

\[ \phi'' = i \rho_r \left( u_0 \psi'' - \lambda^2 \phi + \lambda^2 \phi + P_r D_u (\lambda^2 \psi - \psi''), \]

(37)

\[ \psi'' = i \sigma_c (u_0 \psi'' + c_0' \psi) + (\lambda^2 + S_c \gamma \psi' + S_c \sigma_c (\lambda^2 \phi - \phi''), \]

(38)

with the boundary conditions

\[ \psi' = u_0, \quad \psi = 0, \quad \theta_1 = -\theta, \quad c_1 = -c_0 \text{ on } y = 0, \]  

\[ \psi' = 0, \quad \psi = 0, \quad \theta_1 = 0, \quad c_1 = 0 \text{ on } y = 1. \]  

(39)

By considering series expansion for small \( \lambda \) (or \( k < 1 \)) of the form

\[ \psi(\lambda y) = \sum_{j=0}^{\infty} \lambda^j \psi_j, \quad \phi(\lambda y) = \sum_{j=0}^{\infty} \lambda^j \phi_j, \]

(40)

putting (40) into equations (36)–(39) on restriction to the real parts of the solutions for the perturbed quantities and retaining up to order \( \lambda^2 \), we obtained the following sets of differential equations:

\[ O(\lambda^0): \quad \psi_0'' - H \psi_0'' = G_1 \phi_0' + G_2 \psi_0, \quad \phi_0'' = -P_r D_u \phi_0', \quad \psi_0' = \sigma_c (u_0 \psi_0' + c_0' \psi_0) + S_c \gamma \psi_0' - S_c \sigma_c \phi_0', \]

(41)

\[ O(\lambda): \quad \psi_1'' - H \psi_1'' = i (u_0 \psi_1'' - u_0' \psi_1) + G_1 \phi_1' + G_2 \psi_1', \quad \phi_1'' = i \rho_r (u_0 \phi_1'' + \theta_0' \phi_1) - P_r D_u \phi_1', \quad \psi_1'' = i \sigma_c (u_0 \psi_1'' + c_0' \psi_1) + S_c \gamma \psi_1' - S_c \sigma_c \phi_1', \]

(42)

\[ O(\lambda^2): \quad \psi_2'' - H \psi_2'' = i (u_0 \psi_2'' - u_0' \psi_2), \quad 2 \psi_0' + G_1 \phi_2' + G_2 \psi_2', \quad \phi_2'' = i \rho_r (u_0 \phi_2'' + \theta_0' \phi_2) + \theta_0' \psi_2), \quad \psi_2'' = i \sigma_c (u_0 \psi_2'' + c_0' \psi_2) + S_c \gamma \psi_2' - S_c \sigma_c \phi_2', \]

(43)

with the corresponding boundary conditions

\[ \psi_0'' = u_0, \quad \psi_0' = 0, \quad \phi_0'' = 0, \quad \psi_0' = -c_0 \text{ on } y = 0, \]  

\[ \psi_0' = 0, \quad \psi_0 = 0, \quad \phi_0 = 0, \quad \psi_0 = 0 \text{ on } y = 1, \]

(44)

\[ \psi_j' = 0, \quad \psi_j = 0, \quad \phi_j = 0, \quad \psi_0 = 0 \text{ on } y = 0, \quad \psi_j' = 0, \quad \psi_j = 0, \quad \phi_j = 0, \quad \psi_0 = 0 \text{ on } y = 1, \quad \forall j \geq 1. \]  

(45)

The zeroth-order problems, made up of equations (20)–(22) with boundary condition (23) and the first-order
problems, made up of equations (41)–(43) with the boundary conditions (44) and (45) are solved, using the Adomian decomposition method programme written by [19] with MAPLE 14 software and obtained the expression for \((u_0, \theta_0 \text{ and } c_0)\) and \((u_1, v_1, \theta_1 \text{ and } c_1)\) as the zeroth-order and first-order solutions, respectively, where \(\lambda x\) is taken to be \((\pi/2)\) following [2]. The solutions are not presented here for the sake of brevity.

4. Discussion of the zeroth-order and first-order results

The primary objective of this paper is to investigate the effects of Soret \(S_r\), Dufour \(D_u\) and chemical reaction \(\gamma\) on heat and mass transfer by free convection flow through a wavy/irregular channel under the influence of an externally applied magnetic field and heat source/sink. This objective is accomplished by evaluating numerically, the expressions for the zeroth-order and the first-order velocity, temperature and concentration profiles. The solutions are presented through graphs.

In the numerical discussion that follows, for physical reality, we take Prandtl number to be 0.71 which corresponds to the air at 200°C. Schmidt number is chosen to represent the presence of diffusing chemical species to stimulate physically realistic situations. In the absence of chemical reaction, we have \(\alpha = 0\). Physically, \(m_1, m_2 = 1\) means equal wall temperatures and concentrations. In the absence of chemical reaction, we have \(\gamma = 0\) while \(\gamma < 0\) corresponds to exothermic chemical reaction and \(\gamma > 0\) corresponds to endothermic chemical reaction. The geometric parameters representing the waviness/roughness of the wall (the amplitude \(\epsilon\), the wavelength \(\lambda\) and \(\lambda x\)). The amplitude \(\epsilon > 0 = 0.25\), characteristic of dilated channel and \(\lambda x = \pi/2\) have been fixed while \(\lambda = 0.001, 0.002\) is varied. The values of the other parameters are chosen arbitrarily.

4.1. Discussion of the zeroth-order results

4.1.1. Velocity profiles

In order to get a clear insight of the physical problem, the velocity, temperature and concentration profiles have been discussed by assigning numerical values to various parameters encountered in the problem. The results are presented graphically and conclusions are drawn for the flow field and other physical quantities of interest that have significant effects. To test the validity of our results, a comparison of the present results with those of the previous works [1,2] are performed by setting the introduced new parameters (i.e \(D_u, S_r, H, G_2\) and \(\gamma\)) to zero and excellent agreements were obtained (see Figures 2 and 3).

The zeroth-order velocity \(u_0\) profiles when \(m_1 = -1\) are plotted against \(y\) in Figure 2. It is observed that in the presence of heat source \((\alpha > 0)\) with an increase in the free convection parameter \(G_1\), the velocity \(u_0\) increases across the entire channel width (curves III and VI). When there is heat sink \((\alpha < 0)\) and the free convection parameter \(G_1\) increases, the velocity \(u_0\) decreases across the entire channel width (curves I and IV). In the absence of heat generation or absorption \((\alpha = 0)\), the fluid velocity increases in the first half of the channel width \((y = 0.5)\) and then decreases with an increase in the free convection parameter \(G_1\) (curves II and V). However, when the heat source parameter \(\alpha\) increases with constant free convection parameter \(G_1\), the velocity \(u_0\) increases considerably (curves I, II, III) and (curves IV, V, VI).

Figure 3 depicts the zeroth-order velocity \(u_0\) profile when \(m_1 = 2\). It is noticed that the fluid velocity \(u_0\) increases generally as the free convection parameter \(G_1\) increases for all the value of heat generation parameter \(\alpha\) (curves I and IV, II and V, III and VI). On fixing the

![Figure 2. Zeroth-order velocity \(u_0\) profile, \(m_1 = -1, m_2 = 0, D_u = 0, S_r = 0, H = 0, G_2 = 0, \gamma = 0, P_r = 0.71\) and \(S_c = 0.60\).](image)
free convection parameter $G_1$ and increasing the heat source parameter $\alpha$, it is found that the velocity ($u_0$) also increases across the channel width (curves I, II and III) and (curves IV, V and VI).

Figure 4 shows the effect of MHD ($H$) on the fluid flow when $m_1 = m_2 = -1$. It is clearly seen that when there is an increase in $H$ with constant free convection parameters $G_1$ and $G_2$, the velocity $u_0$ decreases across the entire channel width (curves I, II, III) and (curves IV, V, VI). When the free convection parameters $G_1$ and $G_2$ increase with a fixed magnetic parameter $H = 0.1$, the velocity increases to a certain point $y = 0.5$ on the channel width and then decreases (curves I and IV). For $H = 1$ and $H = 3$, the velocity increases up to $y = 0.4$ (curves II and V) and $y = 0.28$ (curves III and VI), respectively, and then decreases.

Figure 5 represents the effects of magnetic field ($H$) when $m_1 = m_2 = 2$. It is observed that an increase in $H$ with constant free convection parameters $G_1$ and $G_2$ leads to a decrease in velocity $u_0$ (curves I, II, III) and...
(curves IV, V, VI). We also noticed that for an increase in free convection parameters $G_1$ and $G_2$ with a fixed magnetic parameter $H$, the velocity $u_0$ increases (curves I and IV, II and V, III and VI).

The effects of chemical reaction ($\gamma$) is presented in Figure 6 for $m_1 = m_2 = -1$. It is clearly seen that an increase in $\gamma$ with a fixed free convection parameters $G_1$ and $G_2$ leads to a decrease in velocity ($u_0$) profile (curves I, II, III) and (curves IV, V, VI). An increase in $G_1$ and $G_2$ with a fixed chemical reaction parameter, leads to an increase in the velocity ($u_0$) profile to a particular point on the width of the channel and then decreases (curves I and IV, II and V, III and VI).

For $m_1 = m_2 = 2$. Figure 7 described the effects of chemical reaction on the velocity($u_0$) profiles. It is observed that when the free convection parameters $G_1$ and $G_2$ are fixed, the velocity $u_0$ decreases with an increase in chemical reaction parameter $\gamma$ (curves I, II, III) and (curves IV, V, VI). Also, when free convection parameter increases the velocity increases with constant chemical reaction parameter (curves I and IV, II and V, III and VI).

Figure 8, when $m_1 = m_2 = -1$, shows that an increase in Dufour parameter $D_u$ with constant free convection parameters leads to a decrease in velocity profile (curves I, II, III) and (curves IV, V, VI). It is also noticed that an increase in free convection parameters with constant Dufour parameter increases the velocity ($u_0$) profile to a particular point on the channel width and then decreases (curves I and IV, II and V, III and VI).

In Figure 9, when $m_1 = m_2 = 2$, it is observed that an increase in Dufour parameter with constant free convection parameters decreases the velocity ($u_0$) profiles (curves I, II, III) and (curves IV, V, VI). Reverse is the case when Dufour parameter is kept constant with an increase in free convection parameters.

It is clearly seen in Figure 10 that the velocity ($u_0$) profiles increase across the entire channel width with an increase in Soret parameter when the free convection parameter is kept constant for $m_1 = m_2 = -1$ (curves I, II, III) and (curves IV, V, VI). Reverse is the case when free convection parameters increases with a constant Soret parameter.

For $m_1 = m_2 = 2$, Figure 11 shows that when the free convection parameters are fixed, the velocity ($u_0$) profiles increase with an increase in Soret parameter (curves I, II, III) and (curves IV, V, VI). The same behaviour is observed for velocity when there is an increase in free convection parameters.
convection parameters with constant Soret parameter (curves I and IV, II and V, III and VI).

4.1.2. Temperature profiles
As it was done in the discussion on the zeroth-order velocity profiles, we begin our zeroth-order temperature profiles by carrying out a comparison of the present and previous results.

Figure 12 depicts the results of the variation of zeroth-order temperature with $y$ when the new parameters (i.e $S_r$, $D_u$, $H$ and $\gamma$) are zero. It is seen clearly that when $m_1 = -1$, the temperature ($\theta_0$) profiles increase with an increase in heat parameter $\alpha$. It is also noticed that in the absence of heat sink/source ($\alpha = 0$), the temperature ($\theta_0$) profile is a linearly decreasing function of $y$ while in the presence of heat sink or source it is parabolic in nature. When $m_1 = 2$, the temperature ($\theta_0$) profile behaved in the opposite way for all values of heat parameter $\alpha$.

Figure 13 shows the effects of Soret on the temperature $\theta_0$ profiles. It is clearly seen that an increase in Soret number with constant wall temperature ratios
Figure 11. Zeroth-order velocity $u_0$ profile, $m_1 = m_2 = 2, \alpha = -5, H = 3.0, P_r = 0.71, S_c = 0.60$ and $\gamma = 4$.

Figure 12. Zeroth-order temperature $\theta_0$ profile, $S_r = 0, D_u = 0, m_2 = 0, P_r = 0.71, S_c = 0.60$ and $\gamma = 0$.

Figure 13. Zeroth-order temperature $\theta_0$ profile, $\alpha = -5, D_u = 0.60, P_r = 0.71, S_c = 0.60$ and $\gamma = 4$.

($m_1 = m_2 = -1$), the temperature $\theta_0$ profiles decrease across the entire channel width (curves I, II, III) and when $m_1 = m_2 = 2$, the temperature ($\theta_0$) profiles remain the same in behaviour as we have when $m_1 = m_2 = -1$ (curves IV, V, VI).

Figure 14 deals with the effects of chemical reaction on temperature ($\theta_0$). It is observed that when $m_1$ and $m_2$ are fixed, temperature ($\theta_0$) profiles increase with an increase in the chemical reaction parameter, $\gamma$. In both cases the curves are parabolic in nature (curves I, II, III) and (curves IV, V, VI).

Figure 15 depicts the effects of Dufour, on the temperature $\theta_0$. We noticed that the temperature $\theta_0$ profile increases with an increase in Dufour number $D_u$. In both cases the curves are parabolic in nature (curves I, II, III) and (curves IV, V, VI).
Figure 14. Zeroth-order temperature $\theta_0$ profile, $\alpha = -5, D_u = 0.60, P_r = 0.71, S_c = 0.60$ and $S_r = 2$.

Figure 15. Zeroth-order temperature $\theta_0$ profile, $\alpha = -5, \gamma = 4, P_r = 0.71, S_c = 0.60$ and $S_r = 2$.

Figure 16. Zeroth-order concentration $c_0$ profile, $\gamma = 4, P_r = 0.71, S_c = 0.60$ and $S_r = 2$.

4.1.3. Concentration profiles

Figure 16 shows that on fixing wall concentration ratio $m_2 = -1$, the concentration $c_0$ profiles decrease with an increase in heat source parameter $\alpha$ (curves I, II, III). The concentration profiles behaved the same way as when $m_2 = -1$ for $m_2 = 2$ with an increase in heat source parameter $\alpha$ (curves IV, V, VI). The curves I, II, III are parabolic functions of $y$ while curves IV, V, VI are parabolic increasing functions of $y$.

Figure 17 reveals the effects of Soret number on the concentration ($c_0$) profiles. We noticed that when concentration ratio $m_2$ is constant, there is an increase in
concentration \((c_0)\) profiles with an increase in Soret number (curves I, II, III) and (curves IV, V, VI). The curves are parabolic in nature.

Figure 18 shows the effects of chemical reaction \((\gamma)\) on the concentration \((c_0)\) profiles. It is observed that for a fixed concentration ratio \(m_2\) and an increase in chemical reaction parameter \((\gamma)\) leads to a decrease in concentration \((c_0)\) profiles, which are parabolic in nature (curves I, II, III) and (curves IV, V, VI).

4.2. Discussion of the first-order results

4.2.1. Velocity profiles

Figures 19–23 revealed the behaviour of the fluid velocity \(u(1)\) profiles along the channel length. Figure 19 presents the behaviour of the perturbed velocity quantity \(u(1)\) when \(m_1 = -1\) and the embedded parameters are set to zero. It is observed that in the presence of heat sinks, the velocity \(u(1)\) increases to a particular point of \(y (y = 0.5)\) and then decreases with constant free convection parameter \(G_1\) and frequency parameters \(\lambda\) (curves I and II, VII and VIII). On the other hand, when heat source is considered, there exist an increase in the velocity \(u(1)\) up to \(y = 0.3\), followed by a decrease up to \(y = 0.7\) and finally an increase for \(y > 0.7\) (curves II and III, VIII and IX). It is also noticed that with an increase in \(G_1\) or \(\lambda\), the velocity increases close to the walls of the channel and decreases in between the walls (curves I and VII, II and VIII, III and IX) or (curves I and IV, II and V, III and VI).

The effect of MHD parameter \(H\) on the fluid flow when \(m_1 = m_2 = -1\) is shown in Figure 20. It is clearly seen that when there is an increase in \(H\) for constant free convection parameters \(G_1, G_2\) and frequency parameters \(\lambda\), the velocity increases to a point \((y = 0.25)\), decreases to another point \((y = 0.7)\) and then increases (curves I, II, III and VII, VIII, IX). When there is an increase in the frequency \(\lambda\) or free convection \(G_1, G_2\) parameters with constant value of \(H\), the velocity increases to certain value of \(y(y = 0.25)\) and decreases to \(y = 0.70\) and then increases again (curves I and IV, III and VI) or (curves I and VII, III and IX).

Figure 21 shows the effect of Dufour parameter \(D_u\) on the fluid flow when \(m_1 = m_2 = -1\). It is observed that with an increase in the Dufour parameter \(D_u\) when frequency \(\lambda\) and free convection \(G_1, G_2\) parameters are constant, there is an increase in velocity up to \((y = 0.25)\), a decrease up to \((y = 0.7)\) and then an increase. (curves I, II and III) and (curves VII, VIII and IX). It is also noticed that with constant Dufour parameter \(D_u\) and an increase in frequency \(\lambda\) or free convection \(G_1, G_2\) parameters, the
Figure 19. First-order velocity $u(1)$ profile, $m_1 = -1, \, Pr = 0.71, \, Sr = 0, \, \gamma = 0, \, Sc = 0, \, Du = 0, \, G_2 = 0, \, m_2 = 0$ and $H = 0$.

Figure 20. First-order velocity $u(1)$ profile, $m_1 = m_2 = -1, \, Pr = 0.71, \, Sr = 2, \, \gamma = 4, \, Sc = 0.60, \, Du = 0.60$ and $\alpha = -5$.

Figure 21. First-order velocity $u(1)$ profile, $m_1 = m_2 = -1, \, Pr = 0.71, \, Sr = 2, \, \gamma = 4, \, Sc = 0.60, \, H = 3.0$ and $\alpha = -5$.

Velocity increases to a particular point $y = 0.25$ on the width of the channel and then decreases to another point $y = 0.7$ after which it increases (curves I and IV, II and V, III and VI) or (curves I and VII, II and VIII, III and IX).

The effect of chemical reaction parameter $\gamma$ on the fluid flow when $m_1 = m_2 = -1$ is depicted in Figure 22. It is clearly seen that with an increase in chemical reaction parameter when the frequency $\lambda$ and free convection $G_1, G_2$ parameters are kept constant, the velocity increases to a particular point $y = 0.25$ and leads to a decrease up to $y = 0.70$ before increasing again along the width of the channel. (curves I, II, III) and (curves VII, VIII IX). It is also observed that with constant chemical reaction parameter $\gamma$ and an increase in the frequency $\lambda$ or free convection $G_1, G_2$ parameters, there is an increase in velocity up to $y = 0.25$, a decrease
Figure 22. First-order velocity $u(1)$ profile, $m_1 = m_2 = -1$, $P_r = 0.71$, $S_r = 2$, $D_u = 0.60$, $S_c = 0.60$, $H = 3.0$ and $\alpha = -5$.

Figure 23. First-order velocity $u(1)$ profile, $m_1 = m_2 = -1$, $P_r = 0.71$, $\gamma = 4$, $D_u = 0.60$, $S_c = 0.60$, $H = 3.0$ and $\alpha = -5$.

Figure 24. First-order velocity $v(1)$ profile, $m = -1$, $P_r = 0.71$, $S_r = 0$, $\gamma = 0$, $S_c = 0$, $D_u = 0$, $G_2 = 0$, $m_2 = 0$ and $H = 0$.

between $y = 0.25$ and 0.70 while it then increases along the width of the channel (curves I and IV, II and V, III and VI) or (curves I and VII, II and VIII, III and IX).

Figure 23 describe the effect of Soret parameter $S_r$ on velocity $u(1)$ when $m_1 = m_2 = -1$. It is noticed that with an increase in the Soret parameter when the frequency $\lambda$ and the free convection $G_1, G_2$ parameters are constants, the velocity remains the same up to $y = 0.25$, increases up to $y = 0.70$ and then decreases. (curves I, II, III) and (curves VII, VIII, IX). When the frequency or free convection parameters increases with constant Soret parameter $S_r$, it is observed that the velocity increases to a certain point $y = 0.25$, decreases between $y = 0.25$ and $y = 0.70$, then increases (curves I and IV, II and V, III and VI) or (curves I and VII, II and VIII, III and IX).

The behaviour of the fluid velocity $v(1)$ perpendicular to the channel is discussed in Figures 24–29. From Figure 24 it is noticed that when there is an increase in the heat source parameter $\alpha$, the velocity $v(1)$ profile decreases with constant free convection $G_1$ and frequency $\lambda$ parameters (curves I, II, III) and (curves VII, VIII, IX). It is also observed that with varying free convection $G_1$ or frequency $\lambda$ parameter, there is an increase in velocity $v(1)$ profile when the heat source parameter
Figure 25. First-order velocity \( v(1) \) profile, \( m_1 = m_2 = -1, Pr = 0.71, Sr = 2, \gamma = 4, Sc = 0.60, Du = 0.60 \) and \( H = 3.0 \).

Figure 26. First-order velocity \( v(1) \) profile, \( m_1 = m_2 = -1, Pr = 0.71, Sr = 2, \gamma = 4, Sc = 0.60, Du = 0.60 \) and \( \alpha = -5 \).

Figure 27. First-order velocity \( v(1) \) profile, \( m_1 = m_2 = -1, Pr = 0.71, Sr = 2, \gamma = 4, Sc = 0.60, H = 3.0 \) and \( \alpha = -5 \).

\( \alpha < 0 \) (curves I, IV) and (curves I, VII) and a decrease when \( \alpha \geq 0 \) (curves II and V, III and VI) and (curves II and VIII, III and IX).

Figure 25 shows the effect of the embedded parameters on the fluid velocity \( v(1) \). It is clearly seen that with an increase in heat source parameter \( \alpha \), there is a decrease in velocity \( v(1) \) when the free convection \( G_1, G_2 \) and frequency \( \lambda \) are kept constant (curves I, II, III) and (curves VII, VIII, IX). We also realized that the velocity \( v(1) \) decreases with constant heat source parameter \( \alpha \), when there is an increase in free convection \( G_1, G_2 \) or frequency \( \lambda \) parameters (curves I and IV, II and V, III and VI) and (curves I and VII, II and VIII, III and IX).

The effect of MHD parameter \( H \) on the fluid velocity \( v(1) \) is as shown in Figure 26. It is observed that there is a decrease in velocity \( v(1) \) when the MHD parameter increases from \( H = 0.1 \) to \( H = 1.0 \) with constant free convection \( G_1, G_2 \) and frequency \( \lambda \) parameters (curves I and II) and (curves VII and VIII). There is also a decrease in velocity \( v(1) \) profile when there is an increase in MHD parameter from \( H = 1.0 \) to \( H = 3.0 \) (curves II and III) and (curves VIII and IX). It is, moreover, clearly seen from the
Figure 28. First-order velocity $v(1)$ profile, $m_1 = m_2 = -1, Pr = 0.71, S_r = 2, D_u = 0.60, S_c = 0.60, H = 3.0$ and $\alpha = -5$.

Figure 29. First-order velocity $v(1)$ profile, $m_1 = m_2 = -1, Pr = 0.71, \gamma = 4, D_u = 0.60, S_c = 0.60, H = 3.0$ and $\alpha = -5$.

The figure shows that when there is an increase in the free convection parameters $G_1, G_2$ or frequency $\lambda$ parameters, there is a decrease in velocity $v(1)$ profiles with constant MHD parameter $H$ (curves I and IV, II and V, III and VI) and (curves I and VII, II and VIII, III and IX).

Figure 27 reveals the effect of Dufour parameter $D_u$ on the fluid velocity $v(1)$ profiles. From curves (I, II, III) and curves (VII, VIII, IX) of the figure, it is noticed that with increase in Dufour parameter, there is an increase in velocity $v(1)$ profiles when the free convection parameters $G_1, G_2$ and frequency $\lambda$ parameters are constant. But with an increase in frequency parameter $\lambda$ or free convection parameters $G_1, G_2$, it is clearly seen that the velocity $v(1)$ profiles decrease for a fixed value of Dufour parameter (curves I and IV, II and V, III and VI) or (curves I and VII, II and VIII, III and IX).

Figure 28 illustrates the effect of chemical reaction parameter $\gamma$ on the fluid velocity $v(1)$ profiles. It is observed from the figure that the effects of the chemical reaction parameter on the fluid velocity $v(1)$ profile are the same as those of Dufour parameter $D_u$ in Figure 27.

Figure 29 presents the effects of Soret parameter $S_r$ on the fluid velocity $v(1)$ profile. We realized from the figure that with an increase in the Soret parameter, the velocity $v(1)$ profile decreases across the channel width when the free convection parameters $G_1, G_2$ and frequency $\lambda$ parameters are constant (curves I, II, III) and (curves VII, VIII, IX). An increase in each of $G_1$ and $G_2$ and $\lambda$ leads to a decrease to a particular point of $y$ and then an increase when there is an increase in Soret parameter from $S_r = 0.1$ to $S_r = 0.4$ (curves I and IV, II and V) and (curves I and VII, II and VIII). A decrease in velocity $v(1)$ across the channel width is experienced when there is an increase in Soret parameter from $h = 0.4$ to $S_r = 2.0$ (curves III and VI) and (curves III and IX).

4.2.2. Temperature profiles

Figures 30–33 depict the behaviour of the fluid temperature $\theta(1)$ profiles. Figure 30 describes the effect of MHD parameter $H$ on the fluid temperature $\theta(1)$ profile. It is noticed that with an increase in $H$, there is a decrease in the fluid temperature $\theta(1)$ profile when free convection parameters $G_1, G_2$ and frequency parameters $\lambda$ are kept constant, (curves I and IV, II and V, III and VI) or (curves I and VII, II and VIII, III and IX).

We also observed that when there is an increase in free convection parameters $G_1, G_2$ with parameters $\lambda, \alpha, H$ remaining constant or an increase in frequency parameter $\lambda$ with parameters $\alpha, H, G_1, G_2$ being constant, there is a decrease in fluid temperature $\theta(1)$ profiles (curves I and VII, II and VIII, III and IX) or (curves I and IV, II and V, III and VI).

Figure 31 and 32 show the effects of Dufour parameter $D_u$ and chemical reaction ($\gamma$) respectively on the fluid temperature $\theta(1)$ profiles. It is observed that their
effects on fluid temperature remain the same as the effect of MHD parameter $H$ in Figure 30.

Figure 33 reveals the effect of Soret parameter $S_r$ on the fluid temperature $\theta(1)$ profiles. It is clearly seen from the figure that with an increase in $S_r$, there is an increase in temperature $\theta(1)$ profile of the fluid, when the free convection parameters $G_1, G_2$ and frequency $\lambda$ are kept constant (curves I, II, III) and (curves VII, VIII, IX). However, a decrease in the fluid temperature $\theta(1)$ is observed, when there is an increase in the free convection parameters $G_1, G_2$ or frequency parameter $\lambda$, with constant Soret parameter $S_r$ (curves I and IV, II and V, III and VI) and (curves I and VII, II and VIII, III and IX).

4.2.3. Concentration profiles
The behaviour of the fluid concentration $c(1)$ profiles is depicted in Figures 34–37. It is observed from Figure 34 that an increase in heat source parameter $\alpha$, leads to a decrease in fluid concentration $c(1)$ profiles when free convection parameters $G_1, G_2$ and frequency parameter $\lambda$ are constant (curves I, II, III) and (curves VII, VIII, IX). On keeping heat source parameter $\alpha$ constant and increasing the free convection parameters $G_1, G_2$ or frequency parameter $\lambda$, a decrease in fluid concentration $c(1)$ profiles is noticed (curves I and VII, II and VIII, III and IX) or (curves I and IV, II and V, III and VI).
Figure 33. First-order temperature $\theta(1)$ profile, $m_1 = m_2 = -1, P_r = 0.71, D_u = 0.60, \gamma = 4, H = 3.0, S_c = 0.60$ and $\alpha = -5$.

Figure 34. First-order concentration $c(1)$ profile, $m_1 = m_2 = -1, S_c = 0.60, S_r = 2, \gamma = 4, D_u = 0.60, P_r = 0.71$ and $H = 3.0$.

Figure 35. First-order concentration $c(1)$ profile, $m_1 = m_2 = -1, S_c = 0.60, P_r = 0.71, S_r = 2, \gamma = 4, D_u = 0.60$ and $\alpha = -5$.

Figure 36. First-order concentration $c(1)$ profile, $m_1 = m_2 = -1, S_c = 0.60, P_r = 0.71, S_r = 2, D_u = 0.60, H = 3.0$ and $\alpha = -5$. 
Figure 35 illustrates the effect of MHD parameter $H$ on the fluid concentration $c$ profiles. It is clearly seen that with an increase in MHD parameter $H$, there is an increase in fluid concentration $c$ profiles when the free convection $G_1, G_2$ and frequency $\lambda$ are kept constant (curves I, II, III) and (curves VII, VIII, IX). The reverse is the case when there is an increase in free convection parameters $G_1, G_2$ or frequency parameter $\lambda$ with constant MHD parameter $H$ (curves I and IV, II and V, III and VI) and (curves I and VII, II and VIII, III and IX).

Figure 36 deals with the effect of chemical reaction parameter $\gamma$ on the fluid concentration $c$ profiles. It is observed that the behaviour remains the same as that of the effect of MHD in Figure 35.

The effect of Soret parameter $S_r$ on the fluid concentration $c$ profiles is shown in Figure 37. It is noticed that the fluid concentration $c$ profile decreases across the channel width, with an increase in Soret parameter when free convection parameters $G_1, G_2$ and frequency $\lambda$ are constant (curves I, II, III) and (curves VII, VIII, IX). It is also observed that there is a decrease in fluid concentration $c$ profile up to a particular point on the width of the channel and then an increase, with an increase in frequency parameter $\lambda$ or free convection parameters $G_1, G_2$ when $S_r = 0.1$ and $S_r = 0.4$ (curves I and IV, II and V) or (curves I and VII, II and VIII). While a decrease in fluid concentration $c$ profile is observed when $S_r = 2.0$ for an increase in frequency parameter $\lambda$ or free convection parameters $G_1, G_2$ (curves III and VI) or (curves III and IX).

5. Conclusions

A numerical study has been conducted on free convective heat and mass transfer of an incompressible electrically conducting fluid in a finitely long vertical wavy channel, considering Soret, Dufour and chemical reaction effects in the presence of constant heat source or sink. Employing the perturbation technique, the solutions of the dimensionless governing equations are assumed to be of a mean part and disturbance (contribution from the waviness of the wall) part and are evaluated numerically using the Adomian decomposition method with MAPLE 14 software.

Numerical results of the fluid flow are presented for different physical parameters and are shown by means of graphs. From the previous results and discussion, the numerical observations are as follows:

(i) When $H = 0, D_u = 0, S_r = 0$ and $\gamma = 0$, the numerical values are the same with that of Vajravelu and Sastri [1] and Facqobon [2] for $u_0, \theta_0, c_0, u_1, \theta_1$ and $c_1$ for different values of $\alpha, G_1, G_2, m_1, m_2$ and $\lambda$ which confirm the validity of our numerical simulation.

(ii) An increase in the magnetic field parameter $H$, chemical reaction parameter $\gamma$ and Dufour number $D_u$ considerably reduced the mean velocity, but get enhanced due to increase in Soret number $S_r$.

(iii) A rise in the Soret number $S_r$ depreciates the mean temperature profiles of the flow while an increase in Dufour number $D_u$ and chemical reaction parameter $\gamma$ enhanced it.

(iv) Heat source/sink parameter $\alpha$ and chemical reaction parameter $\gamma$ have tendency to decrease the mean concentration profile and Soret number $S_r$ accelerates it.

(v) It is found, in general, that $G_1, G_2, m_1, m_2$ and $\alpha$ strongly enhanced the mean velocity, temperature and concentration.

(vi) On fixing $G_1, G_2, m_1, m_2$ and $\alpha$, the effects of $\lambda, H, D_u, \gamma$ and $S_r$ on the fluid velocity $u_1$ are qualitatively similar.

(vii) Changes in the value of $\alpha, H$ and $S_r$ reduced the fluid velocity $u_1$ perpendicular to the channel length when $G_1, G_2$ and $\lambda$ are fixed but this trend is reversed in the case of $D_u$ and $\gamma$.

(viii) Increase in the value of $H, D_u$ and $\gamma$ diminished the fluid temperature $\theta_1$ considerably when $G_1, G_2$ and $\lambda$ are fixed but Soret number $S_r$ has tendency to increase it.

(ix) The effect of an increase in the Soret number $S_r$ and heat source/sink parameter $\alpha$ suppressed the
concentration $c_1$ when $G_1, G_2$ and $\lambda$ are fixed. This trend is reversed in the effect of $H$ and $\gamma$.

(x) It is evident that the perturbed quantities $u_1, v_1, \theta_1$ and $c_1$ are affected significantly by the free convection parameters $G_1, G_2$, the heat source/sink parameter $\alpha$ and the wavelength parameter $\lambda$.

(xi) The flow pattern of the perturbed part leads to non-uniqueness in the exhibited wave-like trend along the $y$-direction. That is, we record the qualitative differences in the behaviour of the various flows which show clearly the effects of the channel under consideration.

NOMENCLATURE

- $C'$: species concentration at any point in the fluid
- $c$: dimensionless concentration
- $C_s$: concentration susceptibility
- $C_{sw}$: species concentration at the wavy wall
- $c_0$: zeroth-order concentration
- $c_1$: first-order concentration
- $C_p$: specific heat at constant pressure
- $C_i$: concentration of the fluid in static condition
- $d$: distance between the walls
- $D_m$: mass diffusivity coefficient
- $D_U$: diffusion-thermo parameter
- $G_1$: thermal Grashof number
- $G_2$: mass Grashof number
- $m_1$: wall temperature ratio
- $m_2$: wall temperature ratio
- $g_x$: acceleration due to gravity in $x$-direction
- $K_T$: fluid thermal-diffusion ratio
- $k_1$: constant rate of chemical reaction
- $K$: thermal conductivity
- $T'$: dimensional temperature of the fluid
- $T_s$: fluid temperature in static condition
- $T_{sw}$: wavy wall temperature
- $T_1$: temperature of the flat wall
- $T_m$: mean fluid temperature
- $P'$: dimensional fluid pressure
- $p$: dimensionless fluid pressure
- $P_r$: Prandtl number
- $Q$: the constant heat source/sink
- $S_c$: Schmidt number
- $S_i$: thermal-diffusion parameter
- $H$: magnetic field parameter
- $k$: wave number
- $\rho$: fluid density
- $\sigma$: electrical conductivity
- $\beta_0$: externally imposed magnetic field
- $\beta$: magnetic field strength
- $\beta_C$: coefficient of concentration expansion
- $\beta_T$: coefficient of thermal expansion
- $\alpha$: Heat source or sink parameter
- $U', V'$: velocity components along the $(X', Y')$ axes
- $u, v$: dimensionless velocity
- $u_0$: dimensionless zeroth-order velocity
- $u_1, v_1$: dimensionless first-order velocity
- $X', Y'$: dimensional coordinate system
- $x, y$: dimensionless coordinate system
- $\epsilon^*$: irregular wall amplitude
- $\epsilon$: dimensionless amplitude
- $\lambda$: dimensionless wave length of the irregular wall
- $\mu$: dynamic viscosity
- $\nu$: fluid kinematic viscosity
- $\theta$: dimensionless temperature of the fluid
- $\theta_0$: dimensionless zeroth-order temperature profiles
- $\psi'$: stream function
- $\gamma$: chemical reaction parameter
