Abstract
We establish the well-posedness of a strongly damped semilinear wave equation equipped with nonlinear hyperbolic dynamic boundary conditions. Results are carried out with the presence of a parameter distinguishing whether the underlying operator is analytic, $\alpha > 0$, or only of Gevrey class, $\alpha = 0$. We establish the existence of a global attractor for each $\alpha \in [0, 1]$, and we show that the family of global attractors is upper-semicontinuous as $\alpha \to 0$. Furthermore, for each $\alpha \in [0, 1]$, we show the existence of a weak exponential attractor. A weak exponential attractor is a finite dimensional compact set in the weak topology of the phase space. This result ensures the corresponding global attractor also possesses finite fractal dimension in the weak topology; moreover, the dimension is independent of the perturbation parameter $\alpha$. In both settings, attractors are found under minimal assumptions on the nonlinear terms.

Keywords: hyperbolic dynamic boundary condition, semilinear hyperbolic equation, damped wave equation, global attractor, weak exponential attractor

1. Introduction

The problem under consideration in this article draws motivation from viscoelastic material; i.e. physical phenomena that exhibit both elasticity and viscosity when undergoing deformation. In mathematical models that approximate the behavior of non-Hookean materials under high strains, the term $-\Delta u_t$ appearing in the differential equations that model such phenomena not only indicates that the stress is proportional to the strain, but, in addition, the term communicates that the stress is proportional to the strain rate. Thus, such terms appear when modeling viscoelastic materials such as Kelvin–Voigt type materials (see e.g. [29, section 4.9.2] and [31, section 13.10]). In the present work, we allow the term $\omega \Delta u_t$, $0 < \omega \leq 1$, to appear in the sense of a strong damping perturbation to the (weakly) damped semilinear wave equation. This means we are able to include in our model many applications besides viscoelasticity; indeed, our model (see equation (1.4) below) contains the perturbed (homogeneous) sine-Gordon equation,

$$u_t - \omega \Delta u_t + u_t - \Delta u + \sin u = 0,$$

used in modeling the evolution of the current $u$ in a Josephson junction (see [29, 30]). Moreover, the model problem here may be used to describe the perturbed Klein–Gordon wave equation appearing in quantum mechanics (see [42, section IV.3]),

$$u_t - \omega \Delta u_t + u_t - \Delta u + |u|^{\gamma - 1} u = 0,$$

for $1 \leq \gamma \leq 3$.

The damped wave equation,

$$u_t + Au_t + Bu = F(u),$$

(1.1)

has been the topic of several important works, of which we will only mention a few. For standard Dirichlet–Laplacian operators, $A = -\omega \Delta$ and $B = -\Delta$, and any potential $F : D(-\Delta) = H^2(\Omega) \cap H^1_0(\Omega) \to L^2(\Omega)$ locally Lipschitz continuous, [43] established the global existence of strong solutions. No differentiability assumption on $F$ is needed for the result; indeed, the result can be attributed to the local existence theorem for analytic semigroups (see e.g. [37]). Carvalho and Cholewa [7] show the existence of local weak solutions (in $H^1(\Omega) \times L^2(\Omega)$) to (1.1) with $\theta = \omega(-\Delta)^{\theta}$, $\theta \in [\frac{1}{2}, 1]$, $B = -\Delta$, and $F \in C(\mathbb{R})$ satisfying

$$|F(r) - F(s)| \leq \epsilon |r - s|(1 + |r|^{p-1} + |s|^{p-1}),$$

(1.2)

where $1 \leq p \leq \frac{n+2}{n-2}$ for $\Omega \subset \mathbb{R}^n$ bounded and smooth. Or course, of particular importance is the critical nonlinearity $p = 5$. To that end, the same authors prove in [6] the global well-posedness for the problem associated to (1.1). They also show the existence of compact global (universal) attractor in $H^1(\Omega) \times L^2(\Omega)$ with the aid of the dissipation assumption (1.8). For this result, the case $\theta = 1$ is important because the associated operator,

$$A^\theta := \begin{pmatrix} 0 & -I \\ B & A^\theta \end{pmatrix},$$

(1.3)

does not possesses a compact resolvent (see [7, proposition 1]). It is certainly worth mentioning the work [11] who show that the operator (1.3) is of Gevrey class for $\theta \in (0, \frac{1}{2})$. Pata and Squassina prove in [34] that the subcritical problem with $\theta = 1$ admits an exponential attractor of optimal regularity in the standard energy phase space. In [35], the authors Pata and Zelik show the problem with critical and supercritical nonlinearities also admit global attractors.
with optimal regularity. In the present work, we do not consider the critical case, rather, for the existence of a local (mild) solution we will rely on classical semigroup theory. Additionally, our results are presented for the $\theta = 1$ setting.

Much of the present literature on the strongly damped wave equation contains only the case of the Dirichlet boundary condition. Of course, sometimes only trivial modification are required to reproduce the results for Neumann, Robin, or periodic boundary conditions. However, it is becoming increasingly apparent that so-called dynamic boundary conditions should be considered and developed in future mathematical models. The damped wave equation with dissipation appearing (in the sense of frictional damping) on the boundary appears in [44]. Since this result appeared, it has become physically relevant and hence important to adopt dynamic boundary conditions. A source of special emphasis on this front appears quite naturally in the analysis of the process of spinoidal decomposition, relevant to the Cahn–Hilliard equations. We quote [23]:

In most works, the equations are endowed with Neumann boundary conditions for both unknowns $u$ and $w$ (which means that the interface is orthogonal to the boundary and that there is no mass flux at the boundary) or with periodic boundary conditions. Now, recently, physicists have introduced the so-called dynamic boundary conditions, in the sense that the kinetics, i.e. $\partial_t u$, appears explicitly in the boundary conditions, in order to account for the interaction of the components with the walls for a confined system.

The dynamic boundary condition present here in our work (see equation (1.5) below) is of hyperbolic type. A related hyperbolic boundary condition—though not exhibiting surface diffusion—appears in [26]. As mentioned, the present problem is the strongly damped perturbation of the (weakly) damped semilinear wave equation. It describes the dynamics of a wave in a bounded domain under the influence of dissipative effects, the novelty here being that the momentum at the boundary of the domain is not neglected. Hence, an important dynamical feature of our model is the effect of the dynamical flux present on the boundary; i.e. the $\partial_m \mathbf{u}_t$ term which describes the evolution of the surface (tangential) gradient of the velocity component on $\Gamma$. For example, the model problem under consideration may describe a gas experiencing irrotational forces from a rest state in a domain $\Omega$. The surface $\Gamma$, now governed by its own wave equation, acts as a locally reacting dissipation mechanism in response to excess pressure in $\Omega$. Hence, the governing equation (see (1.5) below) describes $\Gamma$ as a so-called locally reactive surface.

For the problem under consideration, let $\Omega$ be a bounded domain in $\mathbb{R}^3$ with boundary $\Gamma := \partial \Omega$ of class $C^2$. We consider the semilinear strongly damped wave equation,

$$u_{tt} - \omega \Delta u_t + u_t - \Delta u + f(u) = 0 \quad \text{in} \quad (0, \infty) \times \Omega,$$

(1.4)

where $0 < \omega \leq 1$ represents the diffusivity of the momentum. The equation is endowed with the dynamic boundary condition, with $0 \leq \alpha \leq 1$,

$$u_{tt} + \partial_n (u + \omega u_t) - \alpha \omega \Delta \mathbf{u}_t + u_t - \Delta \mathbf{u} + u + g(u) = 0 \quad \text{on} \quad (0, \infty) \times \Gamma,$$

(1.5)

and with the initial conditions

$$u(0, x) = u_0(x), \quad u_t(0, x) = u_1(x) \quad \text{at} \quad \{0\} \times \Omega,$$

(1.6)

and

$$u_{t\mid \Gamma}(0, x) = \gamma_0(x), \quad u_{t\mid \Gamma}(0, x) = \gamma_1(x) \quad \text{at} \quad \{0\} \times \Gamma.$$

(1.7)

For the nonlinear terms, we assume $f, g \in C(\mathbb{R})$ satisfies the sign conditions
we assume the growth assumptions hold, for all \( r, s \in \mathbb{R} \),

\[
|f(r) - f(s)| \leq \ell_1 |r - s|(1 + |r|^2 + |s|^2), \\
|g(r) - g(s)| \leq \ell_2 |r - s|(1 + |r|^{p-1} + |s|^{p-1}),
\]

for some positive constants \( \ell_1, \ell_2 \), and \( 2 \leq p < \infty \). We will refer to equations (1.4)–(1.7) under assumptions (1.8)–(1.11) as problem \( P_\alpha \), for \( \alpha \in [0, 1] \).

The main results in this paper are as follows:

- For each \( \alpha \in [0, 1] \), we establish the existence and uniqueness of global mild solutions under only minimal assumptions on the nonlinear terms.
- The global mild solutions generate a locally Lipschitz continuous semiflow on the standard energy phase space.
- For each \( \alpha \in [0, 1] \), the semiflow admits a bounded absorbing set, bounded in the phase space independently of the parameter \( \alpha \).
- The semiflow admits a family of global attractors for each \( \alpha \in [0, 1] \). The required asymptotic compactness for the semiflow is established using a suitable \( \alpha \)-contraction argument.
- Finally, for each \( \alpha \in [0, 1] \), the existence of a so-called weak exponential attractor is proven. This result guarantees the finite (fractal) dimension of the global attractors in the weak topology. The dimension is uniform in \( \alpha \).

\textbf{Notation and conventions.} We take the opportunity here to introduce some notation and conventions that are used throughout the paper. Norms in the associated space are clearly denoted \( \| \cdot \|_B \) where \( B \) is the corresponding Banach space. We use the notation \( \langle \cdot, \cdot \rangle_H \) to denote the inner product on the Hilbert space \( H \). In many calculations, functional notation indicating dependence on the variable \( t \) is dropped; for example, we will write \( u \) in place of \( u(t) \).

Throughout the paper, \( C > 0 \) will denote a generic constant, while \( Q : \mathbb{R}_+ \to \mathbb{R}_+ \) will denote a generic increasing function. All these quantities may depend on various structural parameters, however, unless explicitly stated, they are independent of the perturbation parameter \( \alpha \). Let \( \lambda_\Omega > 0 \) denote the best constant satisfying the Sobolev inequality in \( \Omega \):

\[
\lambda_\Omega \int_\Omega u^2 \, dx \leq \int_\Omega (|\nabla u|^2 + u^2) \, dx.
\]

We will also rely on the Laplace–Beltrami operator \(-\Delta_\Gamma\) on the surface \( \Gamma \). This operator is positive definite and self-adjoint on \( L^2(\Gamma) \) with domain \( D(-\Delta_\Gamma) \). The Sobolev spaces \( H^s(\Gamma) \), for \( s \in \mathbb{R} \), may be defined as \( H^s(\Gamma) = D((-\Delta_\Gamma)^{s/2}) \) when endowed with the norm whose square is given by, for all \( u \in H^s(\Gamma) \),

\[
\|u\|_{H^s(\Gamma)}^2 := \|u\|_{L^2(\Gamma)}^2 + \|(-\Delta_\Gamma)^{s/2}u\|_{L^2(\Gamma)}^2.
\]

On the boundary, let \( \lambda_\Gamma > 0 \) denote the best constant satisfying the Sobolev inequality on \( \Gamma \).
\[
\lambda \int_{\Gamma} u^2 \, d\sigma \leq \int_{\Gamma} (|\nabla u|^2 + u^2) \, d\sigma.
\] (1.14)

Throughout the paper, the reader should be mindful that the results contained here belong to two classes corresponding to the ‘analytic’ problem \( P_\alpha \), where \( \alpha \in (0, 1) \), and to the ‘almost analytic’ or Gevrey problem \( P_0 \) when \( \alpha = 0 \). As for the plan of the paper, in section 2, we review the functional setting and framework for the abstract model problem; in particular, the standard energy phase space is introduced and the appropriate semigroups associated with problem \( P_\alpha \) and problem \( P_0 \) are discussed. In section 3 we determine various properties of the solutions to problem \( P_\alpha \) and problem \( P_0 \). The well-posedness of problem \( P_\alpha \) is obtained by virtue of the analyticity of the underlying operator; i.e. it is the infinitesimal generator of an analytic semigroup, whereas the well-posedness of problem \( P_0 \) relies on the fact that the underlying operator is known to generate a \( C_0 \)-semigroup of contractions of Gevrey class \( \delta \), for \( \delta > 2 \). The above assumptions on the nonlinear terms define a locally Lipschitz functional on the standard energy phase space. Together, semigroup theory provides the existence of local mild solutions which are readily found to be globally defined. Uniqueness of the solutions follows from a continuous dependence estimate utilizing sharp Sobolev embeddings. The mild solutions generate a locally Lipschitz continuous semiflow, uniformly in \( t \) on compact intervals, on the standard energy phase space. In section 3.3 we prove the existence of a bounded absorbing set admitted by the semiflow. This result holds for all problems \( \alpha \in [0, 1] \) with a bound independent of \( \alpha \). In order to establish the existence of a global attractor for each \( \alpha \in [0, 1] \), it suffices to prove the associated semiflows are precompact. As in [7, proposition 1] when \( \theta = 1 \) (which also occurs in our case), the semigroup of solution operators is not compact; which in turn means we cannot rely on the regularizing effects of the solution operators to obtain the required (pre)compactness. Instead, to obtain the precompactness of the solution operators, we rely on the method of \( \alpha \)-contractions (see [12] and the references therein). Finally, in section 3.6 we prove the existence of weak exponential attractors which are compact in the weak topology and bounded in the standard phase space. Using this result, we are able to show the global attractors possess finite fractal dimension only in the weak topology. The final section 4 contains some remarks and notes for future research, as well as some observations and conjectures on the characterization of the domain for the fractional powers of the operator \( A_\alpha \) when \( \alpha \in (0, 1) \).

### 2. Functional setting

We begin with the consequences of the assumptions made on the nonlinear terms. From assumption (1.8) and the definition of the \( H^\theta(\Omega) \) norm, it follows that, for some constants \( \mu_1 \in (0, 1) \) and \( c_1 = c_1(f, |\Omega|) \geq 0 \), and for all \( \xi \in H^\theta(\Omega) \),

\[
\langle f(\xi), \xi \rangle_{L^2(\Omega)} \geq -(1 - \mu_1)\|\xi\|_{L^2(\Omega)}^2 - c_1 \\
\geq -(1 - \mu_1)\|\xi\|_{L^2(\Omega)}^2 - c_1.
\] (2.1)

For some constant \( c_2 = c_2(f, |\Omega|) \geq 0 \), and for all \( \xi \in L^2(\Omega) \),

\[
\int_{\Omega} F(\xi) \, dx \geq -\frac{1 - \mu_1}{2} \|\xi\|_{L^2(\Omega)}^2 - c_2 \\
\geq -\frac{1 - \mu_1}{2} \|\xi\|_{L^2(\Omega)}^2 - c_2.
\] (2.2)
where $F(s) = \int_0^s f(\xi) \, d\xi$. Notice that (1.10) and (1.11) imply, when we fix $s = 0$, that for all $r \in \mathbb{R}$,
\begin{align}
|f(r)| &\leq \ell_1(|r| + |r|^p) + |f(0)|, \quad (2.3) \\
|g(r)| &\leq \ell_2(|r| + |r|^p) + |g(0)|. \quad (2.4)
\end{align}
Together (1.8), (1.12), (2.3), and the continuous embedding $H^s(\Omega) \hookrightarrow L^2(\Omega)$ give the upper-bounds, for all $\xi \in H^s(\Omega)$,
\begin{align}
\int_\Omega F(\xi) \, dx &\leq \ell_3\left(\|\xi\|_{H^s(\Omega)}^2 + \|\xi\|_{H^s(\Omega)}^p + |f(0)|\|\xi\|_{L^2(\Omega)}\right) \\
&\leq C\left(\|\xi\|_{H^{s+1}(\Omega)}^2 + \|\xi\|_{H^p(\Omega)}^p + \|\xi\|_{H^s(\Omega)}^p\right), \quad (2.5)
\end{align}
where $C = C(\ell_1, \lambda_0, \Omega, f)$. Reflecting the above estimates, due to (1.9) and (1.13), there are constants $\mu_2 \in (0, 1)$, $c_3, c_4 > 0$ such that, for all $\xi \in L^2(\Gamma)$,
\begin{align}
\langle g(\xi), \xi \rangle_{L^2(\Gamma)} &\geq -(1 - \mu_2)\|\xi\|_{H^{p+1}(\Gamma)}^2 - c_3 \\
&\geq -(1 - \mu_2)\|\xi\|_{H^p(\Gamma)}^p - c_3, \quad (2.6)
\end{align}
and
\begin{align}
\int_\Gamma G(\xi) \, d\sigma &\geq -\frac{1 - \mu_2}{2} \|\xi\|_{L^2(\Gamma)}^2 - c_4. \quad (2.7)
\end{align}
where $G(s) = \int_0^s g(\xi) \, d\xi$ and $d\sigma$ represents the natural surface measure on $\Gamma$, and with (1.9), (1.14), (2.4), and the embedding $H^s(\Gamma) \hookrightarrow L^p(\Gamma)$, we also find, for all $\xi \in H^s(\Gamma)$,
\begin{align}
\int_\Omega G(\xi) \, dx &\leq \ell_4\left(\|\xi\|_{H^{s+1}(\Gamma)}^2 + \|\xi\|_{H^p(\Gamma)}^p + |g(0)|\|\xi\|_{L^2(\Gamma)}\right) \\
&\leq C\left(\|\xi\|_{H^{s+1}(\Gamma)}^2 + \|\xi\|_{H^p(\Gamma)}^p + \|\xi\|_{H^s(\Gamma)}^p\right), \quad (2.8)
\end{align}
where here $C = C(\ell_2, \lambda_0, \Gamma, g)$.

The ‘standard energy’ phase space and abstract formulation for problem $P_\alpha$, $\alpha \in [0, 1]$, are now given. Let
\[ \mathcal{H}_0 := H^1(\Omega) \times L^2(\Omega) \times H^1(\Gamma) \times L^2(\Gamma). \]
The space $\mathcal{H}_0$ is Hilbert with the norm whose square is given by, for $\zeta = (u, v, \gamma, \delta) \in \mathcal{H}_0$,\[ \|\zeta\|_{\mathcal{H}_0}^2 := \|u\|_{H^1(\Omega)}^2 + \|v\|_{L^2(\Omega)}^2 + \|\gamma\|_{H^1(\Gamma)}^2 + \|\delta\|_{L^2(\Gamma)}^2 \]
\begin{equation}
= (\|\nabla u\|_{L^2(\Omega)}^2 + \|u\|_{L^2(\Omega)}^2) + (\|\nabla v\|_{L^2(\Omega)}^2 + \|v\|_{L^2(\Omega)}^2) + (\|\nabla \gamma\|_{L^2(\Gamma)}^2 + \|\gamma\|_{L^2(\Gamma)}^2) + (\|\nabla \delta\|_{L^2(\Gamma)}^2 + \|\delta\|_{L^2(\Gamma)}^2).
\end{equation}
Before we continue, let us now recall that the Dirichlet trace map, $\text{tr}_D : C^\infty(\bar{\Omega}) \to C^\infty(\Gamma)$, defined by $\text{tr}_D(u) = u|_{\Gamma}$, extends to a linear continuous operator $\text{tr}_D : H^s(\Omega) \to H^{s-1/2}(\Gamma)$, for all $r > \frac{1}{2}$, which is surjective for $\frac{1}{2} < r < \frac{3}{2}$. This map also possesses a bounded right inverse $\text{tr}_D^{-1} : H^{s-1/2}(\Gamma) \to H^s(\Omega)$ such that $\text{tr}_D(\text{tr}_D^{-1}\psi) = \psi$, for any $\psi \in H^{s-1/2}(\Gamma)$.

We find it worthwhile to repeat [25, remark 1.1]:

**Remark 2.1.** In the space $\mathcal{H}_0$, the trace of $u(0) \in L^2(\Omega)$ is not well-defined in $L^2(\Gamma)$. This also means that we cannot identify the second and fourth components of some
ζ = (u₀, v₀, γ₀, δ₀) ∈ H₀ through the trace. However, we will see that along trajectories of problem $P_α$, $α ∈ [0, 1]$, when $t > 0$ the identification $tr_α(u_t) = u_t |_{Γ(t)}$ is allowed. The instantaneous regularization of the solutions to problem $P_α$, $α ∈ [0, 1]$, guarantees the trace is well-defined.

For any $α ∈ [0, 1]$, $ω ∈ (0, 1)$, let
\[
D(α) := \{ ζ = (u, v, γ, δ) ∈ H₀ : v ∈ H¹(Ω), v|_Γ ∈ H¹(Γ), \quad Δ(u + ωv) ∈ L²(Ω), \quad ∂_n(u + ωv)|_Γ - ΔΓ(u|_Γ + αωv|_Γ) ∈ L²(Γ), \quad γ = u|_Γ, \quad δ = v|_Γ \text{ on } Γ \},
\]
and define the linear unbounded operator $A_α : D(A_α) ⊂ H₀ → H₀$ by
\[
A_α := \begin{pmatrix}
0 & I & 0 & 0 \\
Δ - I & ωΔ - I & 0 & 0 \\
0 & 0 & 0 & I \\
-∂_n & -ω∂_n & ΔΓ - I & αωΔΓ - I
\end{pmatrix}
\]
(2.10)

Lemma 2.3 below states that $A_α$ generates a semigroup, which in addition has a regularizing effect on the data depending on whether $α > 0$ or $α = 0$. Before stating the lemma we recall the following definition.

**Definition 2.2.** Let $S(t)$ be a strongly continuous semigroup of bounded linear operators on a Banach space $X$, and let $δ > 1$. We say $S(t)$ is of Gevrey class $δ$ provided that $S(t)$ is infinitely differentiable for all $t > 0$ and, for every compact set $K ⊂ (0, ∞)$ and every $θ > 0$, there exists some constant $C(K, θ)$ such that
\[
\left\| \frac{d^n}{dt^n} S(t) \right\| \leq C(K, θ)θ^n(α!)^δ \quad ∀t ∈ K, \quad ∀n = 0, 1, 2, 3, \ldots
\]

See [41] for both necessary and sufficient conditions for a semigroup to be of Gevrey class. For our purposes, it helps to notice that definition 2.2 is a stronger condition than differentiability, but weaker than analyticity. In particular, the quantitative estimates on the derivatives of the semigroup allow us to analyze (nonlinear) perturbations, as in theorem 3.1 below.

**Lemma 2.3.** For each $α ∈ [0, 1]$, the operator $A_α : D(A_α) ⊂ H₀ → H₀$ given in (2.9)–(2.10) is closed, densely defined, and is the infinitesimal generator of a $C₀$-semigroup of contractions in $H₀$. We denote this semigroup by $e^{A₀t}$ when $α = 0$, or by $e^{A_αt}$ for $α ∈ (0, 1]$.

1. When $α = 0$, the semigroup $e^{A₀t}$ is of Gevrey class $δ$ for all $δ > 2$. More specifically, for $C$ and $R$ sufficiently large, we have the following estimates:
\[
\|A₀e^{A₀t}\|_{C₀(H₀)} \leq \frac{C}{t^2}, \quad ∀t > 0,
\]
\[
\|R(β, A₀)\|_{C₀(H₀)} \leq \frac{C}{|β|^2}, \quad ∀β ∈ (-∞, -R) ∪ (R, ∞).
\]

2. When $α ∈ (0, 1]$, the semigroup $e^{A_αt}$ is analytic in $H₀$.

**Proof.** By the proof of [25, proposition 2.2], we see that, for each $α ∈ [0, 1]$, the operator $A_α$ is closed and densely defined, and it generates a $C₀$-semigroup of contractions on $H₀$. Then by the proof of [25, theorem 1.5], we also find that the semigroup $e^{A₀t}$ is of Gevrey class $δ$ for $δ > 2$, and the semigroup $e^{A_αt}$ is analytic in $H₀$. The only difference is that, whereas in [25] the Poincaré inequality is valid so that the norm $\|u\|_{H₀(Ω)}$ is equivalent to $\|∇u\|_{L²(Ω)}$, in our case we
consider the operator \( I - \omega \Delta \) in place of \(-\omega \Delta\), which gives us control of the full \( H^1(\Omega)\) norm of \( u \). All necessary adjustments are therefore trivial. This completes the proof. \( \square \)

**Remark 2.4.** The two estimates given in part (1) of lemma 2.3 are sufficient, but not (as far as we know) necessary, to show that \( e^{At} \) is of Gevrey class. It is really these estimates, and not merely the fact that \( e^{At} \) is of Gevrey class, which interests us most. Both can be thought of heuristically as a ‘gain of one-half derivative’ type smoothing. Compare this with the case \( \alpha > 0 \), where the combined effect of the damping terms \( \omega \Delta u_t \) in the interior and \( \alpha \omega \Delta \gamma u_t \) on the boundary is to give a whole derivative smoothing. To be precise, if \( \zeta(t) = (u(t), v(t), \gamma(t), \delta(t)) = e^{At} \zeta_0 \) then we have an estimate of the type

\[
\|v(t)\|_{H^\alpha(\Omega)} + \|\delta(t)\|_{H^\alpha(\Gamma)} \leq C\|\zeta_0\|_{H^\alpha}.
\]

If \( \alpha > 0 \), this represents a gain of one derivative, since \( \delta(t) \) is a priori only in \( L^2(\Gamma) \). If \( \alpha = 0 \), we cannot recover a full derivative. However, by trace theory and the fact that \( \delta(t) = v(t)|_\Gamma \), we still obtain

\[
\|\delta(t)\|_{H^\alpha(\Gamma)} = \|v(t)|_\Gamma\|_{H^\alpha(\Gamma)} \leq C\|\zeta_0\|_{H^\alpha}.
\]

This ‘gain of half derivative’ eventually leads to the estimates in part (1) of lemma 2.3. See [25] for details.

The fractional powers of \( A_0 \) are defined here in anticipation of theorem 3.1 below. (Fractional powers of \( A_0 \), \( \alpha \in (0, 1] \) are discussed in section 4.) For any \( \theta \) as in the case \( \alpha > 0 \), let \( \Sigma \) be an open sector in \( \mathbb{C} \) such that \( \mathbb{R}^+ \subset \Sigma \subset \rho(A_0) \). Next, define

\[
A_0^\theta := \frac{1}{2\pi i} \int_{\gamma} \lambda^{-\theta}R(\lambda, A_0)d\lambda,
\]

where \( \gamma \) is any piecewise smooth path in \( \Sigma \) connecting \( ce^{-i\phi} \) to \( ce^{i\phi} \), for some \( \phi > 0 \). Then, for \( \theta > 0 \), the operator \( A_0^\theta \) is defined as the inverse of \( A_0^\theta \) with \( D(A_0^\theta) = \text{Range}(A_0^\theta) \).

**Remark 2.5.** For all \( \alpha \in [0, 1] \), the operator \( A_0 \) is dissipative on \( \mathcal{H}_0 \). Indeed, for any \( \zeta = (u, v, \gamma, \delta) \in \mathcal{H}_0 \),

\[
\langle A_0 \zeta, \zeta \rangle_{\mathcal{H}_0} = -\omega\|\nabla v\|_{L^2(\Omega)}^2 - \|v\|_{L^2(\Omega)}^2 - \alpha\omega\|\nabla \delta\|_{L^2(\Gamma)}^2 - \|\delta\|_{L^2(\Gamma)}^2.
\]

Moreover, if we define an operator \( A_0^\alpha \) with domain

\[
D(A_0^\alpha) := \{ \theta = (\chi, \psi, \phi, \psi_\gamma) \in \mathcal{H}_0 : \psi \in \mathcal{H}^1(\Omega), \psi|_\Gamma \in \mathcal{H}^1(\Gamma), \Delta(\chi - \omega \psi) \in L^2(\Omega), \Delta(\chi|_\Gamma - \alpha \omega \psi_\gamma) \in L^2(\Gamma), \phi = \chi|_\Gamma, \xi = \psi|_\Gamma \text{ on } \Gamma \},
\]

for all \( \alpha \in (0, 1] \) and \( \omega \in (0, 1] \) by

\[
A_0^\alpha := \begin{pmatrix}
0 & -I & 0 & 0 \\
-I & \omega \Delta - I & 0 & 0 \\
0 & 0 & 0 & -I \\
d_{n} & \omega \partial_{n} & -\Delta |_\Gamma + I & \alpha \omega |_\Gamma - I
\end{pmatrix},
\]

then there holds,
\[ \langle A_\alpha \zeta, \theta \rangle_{\mathcal{H}_0} - \langle \zeta, A_\alpha^* \theta \rangle_{\mathcal{H}_0} = \langle \partial_u (u + \omega \psi), \psi - \xi \rangle_{L^2(\Gamma)} - \langle v - \delta, \partial_u (\chi - \omega \psi) \rangle_{L^2(\Gamma)}. \]

Hence, in the limit \( \omega = 0 \), we see the operator \( \{ A_\alpha \}_{\omega=0} \) is the adjoint of the operator \( \{ A_\alpha \}_{\omega=0} \) associated with the weakly damped wave equation endowed with nonlinear hyperbolic boundary conditions. It is important to note that when any operator \( A \) possesses an explicit adjoint \( A^* \), then mild solutions—coming directly from the solution methods of semigroup theory—are in fact equivalent to the variational formulation of weak solutions. For more on this, see [3, section 3].

Finally, define the map \( \mathcal{F} : \mathcal{H}_0 \to \mathcal{H}_0 \) by

\[ \mathcal{F}(\zeta) := \begin{cases} 0 \\ -f(u) \\ 0 \\ -g(\gamma) \end{cases} \]

for all \( \zeta = (u, v, \gamma, \delta) \in \mathcal{H}_0 \). Then problem \( P_\alpha, \alpha \in [0, 1] \), may be put into the abstract form in \( \mathcal{H}_0 \),

\[
\begin{align*}
\frac{d\zeta}{dt} &= A_\alpha \zeta + \mathcal{F}(\zeta) \quad \text{for } t > 0, \\
\zeta(0) &= \zeta_0,
\end{align*}
\]

(2.11)

where \( \zeta(t) = (u(t), u(t), u_\Gamma(t), u_\gamma(t)) \) and \( \zeta_0 = (u_0, u_\Gamma_0, \gamma_0, \delta_0) \in \mathcal{H}_0 \), now where \( v = u_t \) and \( \delta = \gamma \) in the sense of distributions.

The following result will be used to obtain local mild solutions for problem \( P_\alpha, \alpha \in [0, 1] \), in the next section.

**Lemma 2.6.** Under the assumptions (1.10)–(1.11), the map \( \mathcal{F} : \mathcal{H}_0 \to \mathcal{H}_0 \) is locally Lipschitz continuous.

**Proof.** The proof is straightforward. Let us first assume (1.10)–(1.11) hold. By the definition of \( \mathcal{F} \) and the space \( \mathcal{H}_0 \), it suffices to show that \( f : H^1(\Omega) \to L^2(\Omega) \) is locally Lipschitz continuous and that \( g : H^1(\Gamma) \to L^1(\Gamma) \) is locally Lipschitz continuous, both of which follow from rather standard arguments. Indeed, let \( R > 0 \) and \( u, v \in H^1(\Omega) \) be such that \( \|u\|_{L^p(\Omega)} \leq R \) and \( \|v\|_{L^p(\Omega)} \leq R \). Using assumption (1.10), there holds

\[
\|f(u) - f(v)\|_{L^2(\Omega)} \leq C \|u - v\|_{L^2(\Omega)} (1 + |u|^2 + |v|^2) \leq C \|u - v\|_{L^p(\Omega)} (1 + \|u\|_{L^p(\Omega)}^2 + \|v\|_{L^p(\Omega)}^2) \leq Q(R) \|u - v\|_{L^p(\Omega)}.
\]

For the component with \( g \), let \( u, v \in H^1(\Gamma) \) be such that \( \|u\|_{L^q(\Gamma)} \leq R \) and \( \|v\|_{L^q(\Gamma)} \leq R \). Recall \( H^1(\Gamma) \hookrightarrow L^q(\Gamma) \) for \( p \in [1, \infty) \) because \( \Gamma \) is a two-dimensional manifold. Now using (1.11), we find

\[
\|g(u) - g(v)\|_{L^2(\Gamma)} \leq C \|u - v\|_{L^2(\Gamma)} (1 + |u|^p + |v|^p) \leq C \|u - v\|_{L^q(\Gamma)} \left( 1 + \|u\|_{L^{q(p-1)}(\Gamma)}^{p-1} + \|v\|_{L^{q(p-1)}(\Gamma)}^{p-1} \right) \leq Q(R) \|u - v\|_{L^q(\Gamma)}.
\]

(For any \( q > 2 \))

This finishes the proof. \( \square \)
3. The semiflow and attractors

3.1. Semilinear equations with Gevrey semigroups

Before we move on to the discussion of problem $P_\alpha$, $\alpha \in [0, 1]$, we address an abstract problem. The following proposition will become useful when we seek the existence of local mild solutions to abstract ODE,

$$\begin{cases}
\frac{dU}{dt} = AU + F(U) & \text{for } t > 0, \\
U(0) = U_0.
\end{cases} \quad (3.1)
$$

A mild solution is a function $U$ in the variation of parameters form

$$U(t) = e^{At}U_0 + \int_0^t e^{A(t-s)}F(U(s))ds. \quad (3.2)$$

**Theorem 3.1.** Assume the (unbounded) operator $A$ with domain $D(A)$ is the infinitesimal generator of a $C_0$-semigroup of contractions $e^{At}$ on a reflexive Banach space $X$, and let $F : D(F) \subset X \to X$ be a nonlinear operator. Let $U_0 \in X$ be given.

1. Suppose $e^{At}$ satisfies the estimate, for all $t > 0$,

$$\|Ae^{At}\|_{C(X)} \leq Gt^{-\gamma}. \quad (3.3)$$

Note well that this implies that $e^{At}$ is of Gevrey class $\delta$ for all $\delta > \gamma$ (see [41, chapter: Gevrey semigroups]). Assume moreover that $F : D(A') \to X$ is locally Lipschitz continuous for some $0 \leq \theta < \frac{1}{\gamma}$. Then there exists a maximal time $T \in (0, \infty]$ such that (3.2) has a unique solution in

$$C([0, T); X) \cap C((0, T); D(A^{\theta})),$$

Moreover, if $T < \infty$, then $\lim_{t \to T^-} \|U(t)\|_X = +\infty$.

2. In particular, if $e^{At}$ is analytic, then the previous statement (1) holds for $\gamma = 1$.

**Remark 3.2.** Part (2) is well-known and applies to problem $P_\alpha$ for $\alpha > 0$. Concerning problem $P_0$, we will apply part (1) of this theorem with $\gamma = 2$.

Theorem 3.1 is a corollary of the following two propositions.

**Proposition 3.3.** Assume the (unbounded) operator $A$ with domain $D(A)$ is the infinitesimal generator of a $C_0$-semigroup of contractions $e^{At}$ on a reflexive Banach space $X$, and let $F : D(F) \subset X \to X$ be a nonlinear operator. Let $U_0 \in X$ be given.

Suppose that for some $\gamma \geq 1$, $e^{At}$ satisfies the estimate (3.3) for all $t > 0$. Assume moreover that $F : D(A') \to X$ is locally Lipschitz continuous for some $0 \leq \theta < \frac{1}{\gamma}$. Then there exists a maximal time $T \in (0, \infty]$ such that (3.2) has a unique solution in

$$C([0, T); X) \cap C((0, T); D(A^{\theta})),$$

Moreover, if $T < \infty$, then $\lim_{t \to T^-} \|U(t)\|_X = +\infty$.

**Proof.** We will begin by showing that the equation
\[ W(t) = t^{-\theta} A^\theta e^{At} U_0 + t^{-\theta} \int_0^t A^\theta e^{A(t-s)} F(s^{-\theta} A^{-\theta} W(s)) ds \]  

(3.4)

has a unique solution in \( C([0, T]; X) \) for some \( T > 0 \). For \( R > 0, T > 0 \) denote by \( X_{R,T} \) the complete metric space given by

\[ X_{R,T} := C([0, T]; B_X(R)) \quad \text{with} \quad \|V\|_{X_{R,T}} = \sup_{t \in [0, T]} \|V(t)\|_X, \]

where \( B_X(R) := \{ x \in X : \|x\|_X \leq R \} \). We want to show that the map given by

\[ \psi(W)(t) := t^{-\theta} A^\theta e^{At} U_0 + t^{-\theta} \int_0^t A^\theta e^{A(t-s)} F(s^{-\theta} A^{-\theta} W(s)) ds \]

is a contraction on \( X_{R,T} \) for appropriately chosen \( R > 0 \) and \( T > 0 \).

First we recall that by interpolation (e.g. [16, theorem II.5.34]) there exists \( L > 0 \) such that, for all \( x \in D(A) \), the moment inequality holds

\[ \|A^\theta x\|_X \leq L \|x\|_X^{\frac{1}{\theta}} \|Ax\|_X^{\frac{\theta}{\theta}}. \]

Then using the assumption on \( e^{At} \), this gives, for all \( x \in D(A) \),

\[ \|A^\theta e^{At} x\|_X \leq L G_t^{\theta - \theta} \|x\|_X, \]

and since \( D(A) \) is dense in \( X \), it follows that, for all \( t > 0 \),

\[ \|A^\theta e^{At}\|_{L(X)} \leq L G_t^{\theta - \theta}. \]  

(3.5)

Next, since \( F : D(A^\theta) \to X \) is locally Lipschitz, there exists \( K = K(R) \) such that, for all \( x, y \in B_X(R) \),

\[ \|F(A^{-\theta} x) - F(A^{-\theta} y)\|_X \leq K \|x - y\|_X. \]

We will also use below the following kernel estimates:

\[ \int_0^t (t-s)^{-\theta} ds = \int_0^t s^{-\theta} ds = \frac{t^{1-\theta}}{1-\gamma \theta}, \]  

(3.6)

and

\[ \int_0^t (t-s)^{-\theta} s^{-\theta} ds = 2 \int_0^{t/2} (t-s)^{-\theta} s^{-\theta} ds \leq 2 \left( \frac{t}{2} \right)^{1-\gamma \theta} \int_0^{t/2} s^{-\theta} ds = \frac{4^{\theta} t^{1-2\gamma \theta}}{1-\gamma \theta}. \]  

(3.7)

Now observe that for \( W \in X_{R,T}, t > 0 \),
\[ \|\phi(W(t))\|_X \leq t^{\gamma_3} \|A^\delta e^{A t}\|_{\mathbb{L}(X)} \|U_0\|_X + t^{\gamma_3} \int_0^t \|A^\delta e^{A(t-s)}\|_{\mathbb{L}(X)} \|F(s^{-\gamma_3}A^{-\gamma_3}W(s)) - F(0)\|_X \, ds \\
+ t^{\gamma_3} \int_0^t \|A^\delta e^{A(t-s)}\|_{\mathbb{L}(X)} \|F(0)\|_X \, ds \\
\leq LG^\delta \|U_0\|_X + LG^\delta K t^{\gamma_3} \int_0^t (t-s)^{-\gamma_3} s^{-\gamma_3} \|W(s)\|_X \, ds \\
+ LG^\delta t^{\gamma_3} \int_0^t (t-s)^{-\gamma_3} \|F(0)\|_X \, ds \\
\leq LG^\delta \|U_0\|_X + LG^\delta K t^{\gamma_3} \frac{4\delta T^{1-\gamma_3}}{1-\gamma_3} + LG^\delta \|F(0)\|_X \frac{1}{1-\gamma_3}. \]

Therefore,

\[ \sup_{t \in [0, T]} \|\phi(W(t))\|_X \leq LG^\delta \left( \|U_0\|_X + \frac{4\delta T^{1-\gamma_3} + T \|F(0)\|_X}{1-\gamma_3} \right). \]

Similarly, for \( W, V \in X_{R,T}, t > 0 \), we have

\[ \|\phi(W(t)) - \phi(V(t))\|_X \leq t^{\gamma_3} \int_0^t \|A^\delta e^{A(t-s)}\|_{\mathbb{L}(X)} \|F(s^{-\gamma_3}A^{-\gamma_3}W(s)) - F(s^{-\gamma_3}A^{-\gamma_3}V(s))\|_X \, ds \\
\leq LG^\delta K t^{\gamma_3} \int_0^t (t-s)^{-\gamma_3} s^{-\gamma_3} \|W(s) - V(s)\|_X \, ds \\
\leq LG^\delta K t^{\gamma_3} \frac{4\delta T^{1-\gamma_3}}{1-\gamma_3} \|W - V\|_{X_{R,T}}, \]

so that

\[ \|\phi(W) - \phi(V)\|_{X_{R,T}} \leq LG^\delta K \frac{4\delta T^{1-\gamma_3}}{1-\gamma_3} \|W - V\|_{X_{R,T}}. \]

Fix \( R = 2LG^\delta \|U_0\|_X \). Now choose \( T > 0 \) small enough such that

\[ LG^\delta \left( \|U_0\|_X + \frac{4\delta T^{1-\gamma_3} + T \|F(0)\|_X}{1-\gamma_3} \right) \leq R, \]

and

\[ LG^\delta K \frac{4\delta T^{1-\gamma_3}}{1-\gamma_3} < 1. \]

Then it follows that \( \phi \) is a well-defined contraction on \( X_{R,T} \). It therefore has a unique fixed point, which is the same as saying (3.4) has a unique solution in \( C([0, T]; X) \).

To finish, let \( U(t) = t^{-\gamma_3}A^{-\gamma_3}W(t) \) for \( t > 0, U(0) = U_0 \). Then \( U \in C((0, T); D(A^\delta)) \), and for \( t > 0 \) we see by multiplying (3.4) by \( t^{-\gamma_3}A^{-\gamma_3} \) that \( U(t) \) satisfies (3.2). It remains to show that \( \lim_{t \to 0^+} \|U(t) - U_0\|_X = 0 \). Observe:
\[
\|U(t) - U_0\|_X \leq \|e^{A_t}U_0 - U_0\|_X + \int_0^t \|F(s^{-\theta}A^{-\theta}W(s)) - F(0)\|_X \, ds + t\|F(0)\|_X
\]

which converges to zero as \(t \to 0\) by the strong continuity of \(e^{A_t}\). Hence \(U \in C([0, T]; X)\).

Finally, observe that if \(\lim_{t \to T} \|U(T)\|_X = R < +\infty\), then by the argument just given, we can choose a \(T_1 > 0\), depending on \(R\) such that, for all \(t < T_1\), there exists \(V \in C([0, T_1]; X) \cap C((0, T_1]; D(A^\theta))\) satisfying (3.2) with \(U_0\) replaced by \(U(T - \varepsilon)\). Since \(T_1\) depends on \(R\) and not on \(\varepsilon\), we can choose \(\varepsilon = \frac{R}{2}\). Then setting \(\tilde{U}(t) = U(t)\) for \(t \in [0, T]\) and \(\tilde{U}(t) = V(t - T + \frac{R}{2})\) for \(t \in [T, T + \frac{R}{2}]\), we see that \(\tilde{U} \in C([0, T + \frac{R}{2}], X) \cap C((0, T + \frac{R}{2}], D(A^\theta))\) solves (3.2), so \(T\) is not maximal.

\[\square\]

**Remark 3.4.** In the above proof, \(R\) was chosen proportional to \(\|U_0\|_X\) and \(T\) was chosen as a function of \(R\). We derive from the proof that, for small enough \(t > 0\), we have

\[\|e^{A_t}U(t)\|_X \leq C t^{-\gamma} \|U_0\|_X\]

where \(C\) is a constant (for instance \(C = 2LG^\gamma\) as in the proof).

The next proposition requires a lemma.

**Lemma 3.5.** Assume the (unbounded) operator \(A\) with domain \(D(A)\) is the infinitesimal generator of a \(C_0\)-semigroup of contractions \(e^{A_t}\) on a reflexive Banach space \(X\), such that for some \(\gamma > 1\), \(e^{A_t}\) satisfies the estimate (3.3) for all \(t > 0\). Suppose \(f \in L^1(0, T; X)\) is locally Hölder continuous on \((0, T)\). Then for any \(U_0 \in X\), there exists a unique \(U \in C([0, T]; X)\) which is a mild solution of

\[
\begin{align*}
\frac{dU}{dt} &= AU + f \\
U(0) &= U_0,
\end{align*}
\]

and we have \(U \in C((0, T); D(A^{1/\gamma}))\).

**Proof.** By definition of mild solution, we define, for all \(t \in [0, T]\),

\[U(t) = e^{A(t-t_0)}U_0 + \int_{t_0}^t e^{A(t-s)}f(s)\, ds.\]

Since \(e^{A_t}\) satisfies (3.3), it follows that \(t \mapsto A^{1/\gamma}e^{A(t-t_0)}U_0\) is continuous for \(t_0 < t < T\). We need to show that \(\int_{t_0}^t e^{A(t-s)}f(s)\, ds \in D(A^{1/\gamma})\) for all \(t_0 < t < T\) and that it is continuous in \(t\). Note that \(\int_{t_0}^t e^{A(t-s)}f(s)\, ds\) is in \(D(A)\) with \(A \int_{t_0}^t e^{A(t-s)}f(s)\, ds = (e^{A_t} - e^{A_{t_0}})f(t)\), which is also continuous in \(t\) for \(t_0 < t < T\). So it suffices to show that

\[V(t) := \int_{t_0}^t e^{A(t-s)}(f(s) - f(t))\, ds\]

is in \(D(A^{1/\gamma})\) and is continuous in \(t\).

We essentially follow the proof in [37, theorem 4.3.2]. Indeed, the approximations \(V_{\varepsilon}\) defined by
\[ V_t(t) := \int_{t_0}^{t+\varepsilon} e^{A(t-s)}(f(s) - f(t))\,ds, \quad t \geq \varepsilon \]

and \( V(t) = 0 \) for \( t < \varepsilon \) converge to \( V(t) \) as \( \varepsilon \to 0 \) and satisfy \( V(t) \in D(A) \) by (3.3). We want to show that \( A^{\varepsilon} V_t(t) \) converges. For a fixed \( \delta > 0 \) small enough, we can write

\[
\|f(s) - f(t)\| \leq C|s - t|^\beta, \quad \forall|s - t| < \delta,
\]

for some \( \beta \in (0, 1) \), hence

\[
\|A^{\varepsilon}\varepsilon e^{A(t-s)}(f(s) - f(t))\| \leq C|s - t|^{\beta+1} + LG^{\varepsilon}\varepsilon^{-1}\|f(s) - f(t)\| \quad \forall s \in [t_0, t]. \tag{3.9}
\]

Since the right-hand side is integrable, we conclude that

\[
\lim_{\varepsilon \to 0} A^{\varepsilon} V_t(t) = \int_{t_0}^{t+\varepsilon} A^{\varepsilon} e^{A(t-s)}(f(s) - f(t))\,ds
\]

by the dominated convergence theorem. Since \( A \) is closed we get \( V(t) \in D(A^{\varepsilon}) \) with \( A^{\varepsilon} V(t) \) equal to the right-hand side.

Finally, to see that \( A^{\varepsilon} V(t) \) is continuous, we can split it as

\[
A^{\varepsilon} V(t) = \int_{t_0}^{t_0+\delta} A^{\varepsilon} e^{A(t-s)}(f(s) - f(t))\,ds + \int_{t_0+\delta}^{t+\varepsilon} A^{\varepsilon} e^{A(t-s)}(f(s) - f(t))\,ds \tag{3.10}
\]

for arbitrary \( \delta > 0 \). The second term on the right-hand side is continuous in \( t \) by the observations made above. The first term, on the other hand, can be made arbitrarily small by choosing \( \delta > 0 \) small. This completes the proof. \( \square \)

**Remark 3.6.** We note for future reference that, using (3.10) and (3.9), we can estimate

\[
\|A^{\varepsilon} U(t)\| \leq LG^{\varepsilon}(t-t_0)^{\beta}\|U_0\| + LG^{\varepsilon}\varepsilon^{-1}\int_{t_0}^{t+\varepsilon} \|f(s) - f(t)\|\,ds + 2\|A^{\varepsilon} f(t)\|. \tag{3.11}
\]

**Proposition 3.7.** Assume the (unbounded) operator \( A \) with domain \( D(A) \) is the infinitesimal generator of a \( C_0 \)-semigroup of contractions \( e^{At} \) on a reflexive Banach space \( X \), and let \( F : D(F) \subset X \to X \) be a nonlinear operator. Suppose that for some \( \gamma \geq 1 \), \( e^{At} \) satisfies the estimate (3.3) for all \( t > 0 \). Assume moreover that \( F : D(A^\gamma) \to X \) is locally Lipschitz continuous for some \( 0 \leq \theta < \frac{1}{\gamma} \).

Then for any initial data \( U_0 \in D(A^\theta) \) and \( t_0 \geq 0 \) there exists a maximal time \( T \in (t_0, \infty] \) such that

\[
\begin{cases}
\frac{dU}{dt} = AU + F(U) & \text{for } t > 0, \\
U(t_0) = U_0,
\end{cases}
\tag{3.12}
\]

has a unique mild solution in

\[
C([t_0, T]; X) \cap C((t_0, T); D(A^{\varepsilon})).
\]

Moreover, if \( T < \infty \), then \( \lim_{t \to T} \|U(t)\|_X = +\infty \).
Proof. Using the same fixed point argument as in the proof of proposition 3.3, and keeping in mind that \( U_0 \in D(A^\theta) \), we deduce that there exists a unique \( W \in C([t_0, T]; X) \), for small enough \( T > 0 \), such that

\[
W(t) = e^{A(t-t_0)}U_0 + \int_{t_0}^{t} A^\theta e^{A(t-s)}F(A^{-\theta}W(s))ds.
\]

(3.13)

We will prove, further, that \( W(\cdot) \) is locally Hölder continuous in time on \((t_0, T)\). The proof follows the same lines as in [37, theorem 6.3.1]. For \( t_0 \leq t \leq t + h \leq T \) write

\[
W(t + h) - W(t) = e^{A(t + h - t_0)}A^\theta U_0 - e^{A(t - t_0)}A^\theta U_0 + \int_{t_0}^{t} (e^{Ah} - I)A^\theta e^{A(t-s)}F(A^{-\theta}W(s))ds
\]

\[
+ \int_{t}^{t+h} A^\theta e^{A(t+h-s)}F(A^{-\theta}W(s))ds = I_1 + I_2 + I_3.
\]

In order to estimate these terms, first note that for all \( t \in [t_0, T] \), where \( C \) depends on \( sup_{t \in [t_0, T]} \|W(t)\|_X \) and the Lipschitz constant of \( F : D(A^\theta) \to X \). Second, using (3.5) we deduce that for any \( \beta < 1 < \frac{1}{\gamma} \), for any \( Y \in D(A^\beta) \),

\[
\|e^{At}Y - Y\|_X = \left\| \int_0^t A^\beta e^{A(s)}Y ds \right\|_X = \left\| \int_0^t A^\beta e^{A(s)}Y ds \right\|_X
\]

\[
\leq C \int_0^t s^{-(1-\beta)}\|A^\beta Y\|_X ds = C_s^{1-\gamma(1-\beta)}\|A^\beta Y\|_X.
\]

Combining these estimates we deduce

\[
\|I_1\|_X \leq C_{\beta}h^{1-\gamma(1-\beta)}\|A^{\theta+\beta}e^{A(t-t_0)}U_0\|_X \leq C_{\beta}h^{1-\gamma(1-\beta)}(t-t_0)^{-\gamma(\theta+\beta)},
\]

\[
\|I_2\|_X \leq C_{\beta}h^{1-\gamma(1-\beta)}\int_{t_0}^{t} (t-s)^{-\gamma\theta}ds = C_{\beta,\theta}h^{1-\gamma(1-\beta)}(t-t_0)^{-\gamma\theta},
\]

\[
\|I_3\|_X \leq C_{\beta}h^{1-\gamma\theta} \leq C_{\beta,\theta}h^{1-\gamma(1-\beta)},
\]

where \( \beta \) is chosen in the range \( 1 - \frac{1}{\gamma} < \beta < 1 - \theta \). Then these estimates prove that \( W(\cdot) \) is locally Hölder continuous on \((t_0, T)\) with Hölder exponent \( 1 - \gamma(1-\beta) \). Since \( F : D(A^\theta) \to X \) is locally Lipschitz, it follows then that \( t \mapsto F(A^{-\theta}Y(t)) \) is also locally Hölder continuous in time on \((t_0, T)\).

Now we can appeal to lemma 3.5, which tells us that

\[
\begin{cases}
\frac{dU}{dt} = AU + F(A^{-\theta}W) \quad \text{for } t > 0, \\
U(t_0) = U_0 \in D(A^\theta),
\end{cases}
\]

has a unique mild solution \( U \in C([t_0, T]; D(A^\theta)) \cap C((t_0, T); D(A^{1/\gamma})) \) given by

\[
U(t) = e^{A(t-t_0)}U_0 + \int_{t_0}^{t} e^{A(t-s)}F(A^{-\theta}W(s))ds.
\]

(3.14)

The right-hand side is contained in \( D(A) \), hence also in \( D(A^\theta) \), for \( t > t_0 \). We deduce that
\[ A^θ U(t) = e^{A(t-t_0)}A^θ U_0 + \int_{t_0}^t e^{A(t-s)}F(A^{-θ}W(s))ds , \]

and so by uniqueness \( A^θ U(t) = W(t) \). It follows that \( U \) is a mild solution of (3.12). Uniqueness follows from the fact that the solution \( W \) of (3.13) is unique and from formula (3.14).

**Proof of theorem 3.1** For \( U_0 \in X, (3.1) \) has a unique solution \( U \in C([0, T]; X) \cap C((0, T); D(A^θ)) \) by proposition 3.3. By proposition 3.7 with initial data \( t_0 > 0 \) and \( U(t_0) \in D(A^θ) \), we deduce that \( U \in C([t_0, T]; D(A^{1/γ})) \) for arbitrary \( t_0 > 0 \). The conclusion follows.

**Remark 3.8.** Examining the proof of proposition 3.7 and theorem 3.1 and using remarks 3.4 and (3.6), we conclude that for \( t > 0 \) small enough, there is some constant \( C \) such that \( \| A^{1/γ} U(t) \|_X \leq C r^{-1} \| U_0 \|_X \).

### 3.2. Well-posedness of problem \( P_α \)

The definition of mild solution is from [2].

**Definition 3.9.** Let \( T > 0, α \in [0, 1] \). A function \( ζ \in C([0, T]; H_0) \) is called a mild solution of (2.11) (and problem \( P_α, α \in [0, 1] \)) if and only if \( \mathcal{F}(ζ(·)) \in L^1(0, T; H_0) \) and \( ζ \) satisfies the variation of constants formula for all \( t \in [0, T] \),

\[ ζ(t) = e^{A,t}ζ_0 + \int_0^t e^{A(t-s)}\mathcal{F}(ζ(s))ds. \quad (3.15) \]

The mild solution is called a global mild solution if it is a mild solution on \( [0, T] \) for all \( T > 0 \).

**Theorem 3.10.** Assume \( α \in [0, 1] \). Let \( T > 0 \) and \( ζ_0 = (u_0, u_1, γ_0, γ_1) \in H_0 \). There exists a unique mild solution to problem \( P_α \), given by (3.15) satisfying the additional regularity,

\[ ζ \in C([0, T]; H_0) \cap C((0, T]; D(A_α)) \cap C^1((0, T]; H_0) \text{ if } α > 0, \]

\[ ζ \in C([0, T]; H_0) \cap C((0, T]; D(A_α^{1/2})) \text{ if } α = 0. \quad (3.16) \]

For any mild solution to problem \( P_α, α \in [0, 1] \), on \( [0, T] \), the map \( t \mapsto Ε(t) := ζ(t)_{H_0}^2 + 2 \int_Ω F(u(t))dx + 2 \int_Γ G(u(t))dσ \) is \( C([0, T]) \)

and the energy equation,

\[ \frac{d}{dt} Ε + 2ω\|\nabla u_t\|^2_{L^2(Ω)} + 2\|u_1\|^2_{L^2(Ω)} + 2αω\|\nabla_T u_t\|^2_{L^2(Γ)} + 2\|u_t\|^2_{L^2(Γ)} = 0 \quad (3.18) \]

holds for almost all \( t \in [0, T] \). Furthermore, there holds, for any \( T > 0 \) and for all \( t \in [0, T] \),

\[ ζ(t)_{H_0} \leq Q(\|ζ_0\|_{H_0}). \quad (3.19) \]

Therefore, \( T = +∞ \) and any mild solution is globally bounded in \( H_0 \).

**Proof.** First we show the local existence of a unique local mild solution to problem \( P_α, α \in [0, 1] \). By lemma 2.3, the operator \( A_α \) with domain \( D(A_α) \subset H_0 \) satisfies (3.3) with either \( γ = 1 \) (if \( α > 0 \)) or \( γ = 2 \) (if \( α = 0 \)). By lemma 2.6, the functional \( \mathcal{F}: D(A_α^{1/γ}) \subset H_0 \to H_0 \) is locally Lipschitz continuous for any \( 0 \leq θ < 1 \). It follows from theorem 3.1 that for each
\( \zeta_0 = (u_0, u_1, \gamma_0, \gamma_1) \in \mathcal{H}_0 \), there exists \( T > 0 \) and a unique mild solution given by (3.15) to problem \( \mathbf{P}_\alpha \) such that (3.16) holds.

To show that the assertion (3.17) holds, we appeal to the continuity properties of mild solutions (see (3.16)) and the sequential weak continuity of the functional \( \mathcal{F} \) on \( \mathcal{H}_0 \) (this fact follows with simple modifications to the proof of [3, lemma 3.3] for example). The energy identity (3.18) can be derived as in the proof of [3, theorem 3.6]. (Of course, formally, the energy identity may be obtained by multiplying (1.4) by \( u_t \) in \( L^2(\Omega) \).

To show (3.19), integrate (3.18) over \( (0, t) \) and apply (2.2), (2.7), (2.5) and (2.8) to obtain

\[
\int_0^t \left( \| \zeta(t) \|^2 + 2 \int_0^t \| u_t(\tau) \|^2_{H^{\frac{1}{2}}} d\tau + 2 \int_0^t \| u_t(\tau) \|^2_{H^{\frac{1}{2}}} d\tau \right) \leq Q(\| \zeta_0 \|_{\mathcal{H}_0}),
\]

from which (3.19) clearly follows. This finishes the proof. □

The following proposition can be used to show that (mild) solutions to problem \( \mathbf{P}_\alpha \), \( \alpha \in [0, 1] \), depend continuously on initial data.

**Proposition 3.11.** Let \( T > 0 \), \( R > 0 \) and \( \zeta_{01}, \zeta_{02} \in \mathcal{H}_0 \) be such that \( \| \zeta_{01} \|_{\mathcal{H}_0} \leq R \) and \( \| \zeta_{02} \|_{\mathcal{H}_0} \leq R \). Any two mild solutions, \( \zeta^1(t) \) and \( \zeta^2(t) \), to problem \( \mathbf{P}_\alpha \), \( \alpha \in [0, 1] \), on \( [0, T] \) corresponding to the initial data \( \zeta_{01} \) and \( \zeta_{02} \), respectively, satisfy for all \( t \in [0, T] \),

\[
\| \zeta^1(t) - \zeta^2(t) \|_{\mathcal{H}_0} \leq e^{2RT} \| \zeta_{01} - \zeta_{02} \|_{\mathcal{H}_0}.
\]

**Proof.** To prove the continuous dependence in initial conditions, let \( \zeta_{01} = (u_{01}, u_{11}, \gamma_{01}, \gamma_{11}) \), \( \zeta_{02} = (u_{02}, u_{12}, \gamma_{02}, \gamma_{12}) \in \mathcal{H}_0 \) be such that \( \| \zeta_{01} \|_{\mathcal{H}_0} \leq R \) and \( \| \zeta_{02} \|_{\mathcal{H}_0} \leq R \) for some \( R > 0 \). Let \( \zeta^1(t) = (u^1(t), u^1_1(t), u^1_{11}(t)) \) and, respectively, \( \zeta^2(t) = (u^2(t), u^2_1(t), u^2_{11}(t)) \) denote the corresponding solutions of problem \( \mathbf{P}_\alpha \), \( \alpha \in [0, 1] \), on \( [0, T] \) with the initial data \( \zeta_{01} \) and \( \zeta_{02} \). For all \( t \in [0, T] \), set

\[
\bar{\zeta}(t) := \zeta^1(t) - \zeta^2(t)
\]

\[
= (u^1(t), u^1_1(t), u^1_{11}(t)) - (u^2(t), u^2_1(t), u^2_{11}(t)) =: (\bar{u}(t), \bar{u}_1(t), \bar{u}_{11}(t)),
\]

and

\[
\bar{\zeta}_0 := \zeta_{01} - \zeta_{02}
\]

\[
= (u_{01}, u_{11}, \gamma_{01}, \gamma_{11}) - (u_{02}, u_{12}, \gamma_{02}, \gamma_{12})
\]

\[
= (u_{01} - u_{02}, u_{11} - u_{12}, \gamma_{01} - \gamma_{02}, \gamma_{11} - \gamma_{12}) =: (\bar{a}_0, \bar{a}_1, \bar{\gamma}_0, \bar{\gamma}_1).
\]

Then \( \bar{u} \) satisfies the initial boundary value problem

\[
\begin{align*}
\bar{u}_t - \omega \Delta \bar{u} + \bar{u}_1 - \Delta \bar{u} + \bar{u} + f(u^1) - f(u^2) &= 0 & \text{in} \quad (0, T) \times \Omega \\
\bar{u}_t + \partial_\alpha(\bar{u} + \omega \bar{u}_t) - \alpha \omega \Delta \bar{u}_t + \bar{u}_1 - \Delta \bar{u} + \bar{u} + g(u^1) - g(u^2) &= 0 & \text{on} \quad (0, T) \times \Gamma \\
\bar{u}(0, \cdot) &= \bar{u}_0, & \bar{u}_1(0, \cdot) &= \bar{u}_1 \\
\bar{u}_\Gamma(0, \cdot) &= \bar{\gamma}_0, & \bar{u}_{1\Gamma}(0, \cdot) &= \bar{\gamma}_1
\end{align*}
\]

at \( \{0\} \times \Omega \) at \( \{0\} \times \Gamma \).
Multiply (3.22), by $\bar{a}_t$ in $L^2(\Omega)$ to yield, for almost all $t \in [0, T],\$

$$\frac{d}{dt} \|\zeta\|^2_{H_0} + 2\omega \|\bar{a}_t\|^2_{L^2(\Omega)} + 2\alpha \omega \|\bar{a}_t\|^2_{\tilde{H}^1(\Omega)} \leq -2\langle f(u'_t) - f(u^2), \bar{a}_t \rangle_{L^2(\Omega)} - 2\langle g(u'_t) - g(u^2), \bar{a}_t \rangle_{\tilde{H}^1(\Omega)}.$$  

(3.23)

For terms on the right-hand side, first consider when $\alpha \in (0, 1]$.

$$2\|\langle f(u'_t) - f(u^2), \bar{a}_t \rangle_{L^2(\Omega)} \| \leq 2\|\langle f(u'_t) - f(u^2), \bar{a}_t \rangle_{L^2(\Omega)} \| \leq 2\|\|\bar{a}_t\|^2_{L^2(\Omega)} \| \leq C\|\bar{a}_t\|^2_{L^2(\Omega)} 

+ \frac{1}{4\epsilon} \|\bar{a}_t\|^2_{\tilde{H}^1(\Omega)} \langle\zeta\rangle_{L^2(\Omega)} \leq C(1 + \|\bar{a}_t\|^2_{L^2(\Omega)} + \|\bar{a}_t\|^2_{\tilde{H}^1(\Omega)}) \langle\zeta\rangle_{L^2(\Omega)} \leq Q(R) \langle\zeta\rangle_{L^2(\Omega)} \leq Q(R) \left(\frac{\langle\zeta\rangle_{L^2(\Omega)}^2}{4\epsilon} + \frac{1}{4\epsilon} \|\bar{a}_t\|^2_{\tilde{H}^1(\Omega)} \right).$$  

(3.24)

where the last inequality follows from the global bound on the weak solutions (3.19), and

$\varepsilon > 0$ will be chosen later. In a similar fashion, we find for $g$,

$$2\|\langle g(u'_t) - g(u^2), \bar{a}_t \rangle_{L^2(\Omega)} \| \leq Q(R) \left(\frac{\langle\zeta\rangle_{L^2(\Omega)}^2}{4\epsilon} + \frac{1}{4\epsilon} \|\bar{a}_t\|^2_{\tilde{H}^1(\Omega)} \right).$$  

(3.25)

We now choose $\varepsilon > 0$ so that $2\omega - Q(R) \frac{1}{4\epsilon} > 0$; hence eliminating the terms with $\|\bar{a}_t\|^2_{L^2(\Omega)}$ and $\|\bar{a}_t\|^2_{\tilde{H}^1(\Omega)}$ from (3.23). In the case $\alpha = 0$, we can (and do) rely on the Sobolev embedding $H^1(\Gamma) \hookrightarrow L^p(\Gamma)$, for any $p \in [1, \infty)$, and the trace embedding $H^\frac{1}{2}(\Omega) \hookrightarrow H^\frac{1}{2}(\Gamma)$ in order to estimate $g$ with

$$2\|\langle g(u'_t) - g(u^2), \bar{a}_t \rangle_{L^2(\Omega)} \| \leq Q(R) \left(\frac{\langle\zeta\rangle_{L^2(\Omega)}^2}{4\epsilon} + \frac{1}{4\epsilon} \|\bar{a}_t\|^2_{\tilde{H}^1(\Omega)} \right).$$  

(3.26)

and choose $\varepsilon > 0$ so that $2\omega - Q(R) \frac{1}{4\epsilon} > 0$. Combining the remaining terms in (3.23)–(3.25) leaves us with

$$\frac{d}{dt} \|\zeta\|^2_{H_0} \leq Q(R) \langle\zeta\rangle_{L^2(\Omega)} \leq Q(R) \langle\zeta\rangle_{L^2(\Omega)}.$$  

(3.27)

Integrating (3.27) over $[0, T]$, we arrive at (3.21).

We formalize the dynamical system associated with problem $\mathbf{P}_\alpha$.\[\square\]
Corollary 3.12. Let \( \zeta_0 = (u_0, u_1, \gamma_0, \gamma_1) \in \mathcal{H}_0 \) and let \( u \) be the unique (mild) solutions of problem \( P_\alpha \), \( \alpha \in [0, 1] \). For each \( \alpha \in [0, 1] \), define the family of maps \( S_\alpha = (S_\alpha(t))_{t \geq 0} \) by
\[
S_\alpha(t)\zeta_0(x) := (u(t, x, u_0, u_1, \gamma_0, \gamma_1), u_1(t, x, u_0, u_1, \gamma_0, \gamma_1), u_{11}(t, x, u_0, u_1, \gamma_0, \gamma_1))
\]
is the semiflow on \( \mathcal{H}_0 \) generated by problem \( P_\alpha \). The operators \( S(t) \) satisfy
(1) \( S_\alpha(t+s) = S_\alpha(t)S_\alpha(s) \) for all \( t, s \geq 0 \),
(2) \( S_\alpha(0) = I_{\mathcal{H}_0} \) (the identity on \( \mathcal{H}_0 \)),
(3) \( S_\alpha(t)\zeta_0 \to S_\alpha(t_0)\zeta_0 \) for every \( \zeta_0 \in \mathcal{H}_0 \) when \( t \to t_0 \).

Additionally, each mapping \( S_\alpha(t) : \mathcal{H}_0 \to \mathcal{H}_0 \) is Lipschitz continuous, uniformly in \( t \) on compact intervals; i.e. for each \( T > 0 \) and for all \( \zeta_{01}, \zeta_{02} \in \mathcal{H}_0 \) in which \( \|\zeta_{01}\|_{\mathcal{H}_0} \leq R \) and \( \|\zeta_{02}\|_{\mathcal{H}_0} \leq R \), for all \( t \in [0, T] \),
\[
\|S_\alpha(t)\zeta_{01} - S_\alpha(t)\zeta_{02}\|_{\mathcal{H}_0} \leq e^{qRT}\|\zeta_{01} - \zeta_{02}\|_{\mathcal{H}_0}.
\]

Proof. The semigroup properties (1) and (2) are well-known and apply to a general class of abstract Cauchy problems possessing many applications (see [1, 4, 24, 40]; in particular, proofs of property (1) is given in [32, section 1.2.4]). The continuity in \( t \) described by property (3) follows from the definition of the solution (this also establishes strong continuity of the operators when \( t_0 = 0 \)). The continuity property (3.28) follows from (3.21).

Due to the complicated nature of the domain of the operator \( A_\alpha \), we will not report any results on strong solutions to problem \( P_\alpha \) (see e.g. [45, theorem 2.5.6]).

3.3. Dissipativity

The main result depends on the following proposition. It can be found in [5, lemma 2.7].

Proposition 3.13. Let \( X \) be an arbitrary Banach space, and \( Z \subset C([0, \infty); X) \). Suppose that there is a functional \( E : X \to \mathbb{R} \) such that, for every \( z \in Z \),
\[
\sup_{t \geq 0} E(z(t)) \geq -r \quad \text{and} \quad E(z(0)) \leq R
\]
for some \( r, R \geq 0 \). In addition, assume that the map \( t \mapsto E(z(t)) \in C([0, \infty)) \) for every \( z \in Z \) and that for almost all \( t \geq 0 \), the differential inequality holds
\[
\frac{d}{dt}E(z(t)) + m\|z(t)\|_X^2 \leq C,
\]
for some \( m > 0 \), \( C \geq 0 \), both independent of \( z \in Z \). Then, for every \( r > 0 \), there exists \( t_0 \geq 0 \), depending on \( R \) and \( r \), such that for every \( z \in Z \) and for all \( t \geq t_0 \),
\[
E(z(t)) \leq \sup_{\xi \in X} \{ E(\xi) : m\|\xi\|_X^2 \leq C + r \}.
\]
Furthermore, \( t_0 = (r + R)/r \).

Lemma 3.14. There exists \( R_0 > 0 \) so that the set
\[
B_0 := \{ \zeta \in \mathcal{H}_0 : \|\zeta\|_{\mathcal{H}_0} \leq R_0 \}
\]

Proof. The semigroup properties (1) and (2) are well-known and apply to a general class of abstract Cauchy problems possessing many applications (see [1, 4, 24, 40]; in particular, a proof of property (1) is given in [32, section 1.2.4]). The continuity in \( t \) described by property (3) follows from the definition of the solution (this also establishes strong continuity of the operators when \( t_0 = 0 \)). The continuity property (3.28) follows from (3.21).

Due to the complicated nature of the domain of the operator \( A_\alpha \), we will not report any results on strong solutions to problem \( P_\alpha \) (see e.g. [45, theorem 2.5.6]).

3.3. Dissipativity

The main result depends on the following proposition. It can be found in [5, lemma 2.7].

Proposition 3.13. Let \( X \) be an arbitrary Banach space, and \( Z \subset C([0, \infty); X) \). Suppose that there is a functional \( E : X \to \mathbb{R} \) such that, for every \( z \in Z \),
\[
\sup_{t \geq 0} E(z(t)) \geq -r \quad \text{and} \quad E(z(0)) \leq R
\]
for some \( r, R \geq 0 \). In addition, assume that the map \( t \mapsto E(z(t)) \in C([0, \infty)) \) for every \( z \in Z \) and that for almost all \( t \geq 0 \), the differential inequality holds
\[
\frac{d}{dt}E(z(t)) + m\|z(t)\|_X^2 \leq C,
\]
for some \( m > 0 \), \( C \geq 0 \), both independent of \( z \in Z \). Then, for every \( r > 0 \), there exists \( t_0 \geq 0 \), depending on \( R \) and \( r \), such that for every \( z \in Z \) and for all \( t \geq t_0 \),
\[
E(z(t)) \leq \sup_{\xi \in X} \{ E(\xi) : m\|\xi\|_X^2 \leq C + r \}.
\]
Furthermore, \( t_0 = (r + R)/r \).

Lemma 3.14. There exists \( R_0 > 0 \) so that the set
\[
B_0 := \{ \zeta \in \mathcal{H}_0 : \|\zeta\|_{\mathcal{H}_0} \leq R_0 \}
\]
satisfies the following: for all \( \alpha \in [0, 1] \), \( \omega \in (0, 1) \), and for any bounded subset \( B \subset \mathcal{H}_0 \), there is \( t_0 = t_0(\|B\|_{\mathcal{H}_0}, c_1) \geq 0 \), \( i = 1, 2, 3, 4 \), such that \( S_i(t)B \subset \mathcal{B}_0 \) for all \( t \geq t_0 \).

**Proof.** Multiply equation (1.4) by \( \varepsilon u \) in \( \Omega \Ltwo \), where \( \varepsilon > 0 \) will be chosen later, and add the resulting differential identity to the ‘energy’ identity (3.18) to obtain the following identity which holds, for almost all \( t \geq 0 \),

\[
\frac{d}{dt} \left\{ |\zeta|^2_{\mathcal{H}_0} + \varepsilon \langle u, u \rangle_{L^2(\Omega)} + \varepsilon \langle u, u \rangle_{L^2(\Gamma)} + 2 \int_{\Omega} F(u) \, dx + 2 \int_{\Gamma} G(u) \, ds \right\}
\]

\[
+ 2 \omega \| \nabla u_0 \|_{L^2(\Omega)}^2 + 2 \| u_0 \|^2_{L^2(\Omega)} + \varepsilon \omega (\nabla u_0, \nabla u)_{L^2(\Omega)} + \varepsilon \| u_0 \|_{H^1(\Omega)}^2 + \varepsilon \| u_0 \|_{H^1(\Omega)}^2
\]

\[
+ 2 \omega \| \nabla u_1 \|_{L^2(\Gamma)}^2 + 2 \| u_1 \|^2_{L^2(\Gamma)} + \varepsilon \omega (\nabla u_1, \nabla u)_{L^2(\Gamma)} + \varepsilon \| u_1 \|_{H^1(\Gamma)}^2 + \varepsilon \| u_1 \|_{H^1(\Gamma)}^2
\]

\[
+ \varepsilon (f(u), u)_{L^2(\Omega)} + \varepsilon (g(u), u)_{L^2(\Gamma)} = \varepsilon \| u_0 \|_{H^1(\Omega)}^2 + \varepsilon \| u_1 \|_{H^1(\Gamma)}^2.
\]

Define the following functional for all \( \zeta = (u, v, \gamma, \delta) \in \mathcal{H}_0 \) and for each \( \varepsilon > 0 \),

\[
\Psi(\zeta) := |\zeta|^2_{\mathcal{H}_0} + \varepsilon \langle u, v \rangle_{L^2(\Omega)} + \varepsilon \langle \gamma, \delta \rangle_{L^2(\Gamma)} + 2 \int_{\Omega} F(u) \, dx + 2 \int_{\Gamma} G(\gamma) \, ds.
\]

(Also, on trajectories \( (t) = (u(t), u_0(t), \gamma(t), \delta(t), t \geq 0, \) we denote \( \Psi(t) \) by \( \Psi(t) \).)

Observe, with the Cauchy–Schwarz inequality, the Sobolev inequality (1.12), the trace embedding \( H^1(\Omega) \to L^2(\Gamma) \), and (2.2), (2.5), (2.7) and (2.8), a straightforward calculation shows there are constants \( C_1, C_2 > 0 \), such that, for all \( t \geq 0 \),

\[
C_1 \| (t) \|_{\mathcal{H}_0}^2 - 2c_2 - 2c_4 \leq \Psi(t),
\]

and

\[
\Psi(t) \leq C_2 (\| (t) \|_{\mathcal{H}_0}^2 + (u(t))_{H^1(\Omega)}^6 + (u(t))_{H^1(\Gamma)}^6 + (u(t))_{H^1(\Gamma)}^{6+1} + (u(t))_{H^1(\Gamma)}^6).
\]

Moreover, the map \( t \to \Psi(t) \) is \( C^1([0, \infty)) \).

Since \( \omega \in (0, 1) \), in (3.30) we estimate

\[
\varepsilon \omega (\nabla u_0, \nabla u)_{L^2(\Omega)} \geq -\frac{\omega}{4} \| \nabla u_0 \|_{L^2(\Omega)}^2 - \varepsilon^2 \| \nabla u \|_{L^2(\Omega)}^2,
\]

\[
\varepsilon \omega (\nabla u_0, \nabla u)_{L^2(\Omega)} \geq -\frac{\omega}{2} \| u_0 \|_{L^2(\Omega)}^2 - 2 \varepsilon^2 \| u \|_{L^2(\Omega)}^2,
\]

\[
\varepsilon \omega (\nabla u_0, \nabla u)_{L^2(\Gamma)} \geq -\frac{\omega}{4} \| \nabla u_0 \|_{L^2(\Gamma)}^2 - \varepsilon^2 \| \nabla u \|_{L^2(\Gamma)}^2,
\]

\[
\varepsilon \omega (\nabla u_0, \nabla u)_{L^2(\Gamma)} \geq -\frac{\omega}{2} \| u_0 \|_{L^2(\Gamma)}^2 - 2 \varepsilon^2 \| u \|_{L^2(\Gamma)}^2.
\]

We see that combining (3.30)–(3.37), with (2.1) and (2.6), there holds for almost all \( t \geq 0 \),
\[
\frac{d}{dt} \left\{ \| \zeta \|_{H_0}^2 + \varepsilon (u_t, u)_{L^2(\Omega)} + \varepsilon (u_t, u)_{L^2(\Gamma)} + 2 \int_\Omega F(u) \, dx + 2 \int_\Gamma G(u) \, d\sigma \right\} \\
+ \frac{7}{8} \omega \| \nabla u_t \|_{L^2(\Omega)}^2 + \left( 2 - \frac{\omega}{2} - \varepsilon \right) \| u_t \|_{L^2(\Omega)}^2 + \varepsilon (1 - \varepsilon) \| \nabla u \|_{L^2(\Omega)}^2 + \varepsilon \left( \mu_1 - \frac{2 \varepsilon}{\omega} \right) \| u \|_{L^2(\Omega)}^2 \\
+ \frac{7}{8} \alpha \omega \| \nabla u \|_{L^2(\Omega)}^2 + \left( 2 - \frac{\omega}{2} - \varepsilon \right) \| u_t \|_{L^2(\Gamma)}^2 + \varepsilon (1 - \varepsilon) \| \nabla u \|_{L^2(\Gamma)}^2 + \varepsilon \left( \mu_2 - \frac{2 \varepsilon}{\omega} \right) \| u \|_{L^2(\Gamma)}^2 \\
\leq \varepsilon (c_1 + c_3).
\]

(3.38)

Again, \( \omega \in (0, 1) \), so \( 2 - \frac{\omega}{2} - \varepsilon \geq \frac{3}{2} - \varepsilon \). Set

\[
\varepsilon_1 := \min \left\{ \frac{\mu_1 \omega}{2}, \frac{\mu_2 \omega}{2} \right\}.
\]

Then for all \( \varepsilon \in (0, \varepsilon_1) \), the positivity of

\[
m_1 := \min \left\{ \mu_1 - \frac{2 \varepsilon}{\omega}, \mu_2 - \frac{2 \varepsilon}{\omega} \right\} > 0
\]

is assured. Fix any \( \varepsilon^* \in (0, \varepsilon_1) \). After applying both Sobolev inequalities (1.12) and (1.14), we are able to choose a constant \( \nu_1 > 0 \) so that (3.38) becomes

\[
\frac{d}{dt} \| u \|_{H_0}^2 - \nu_1 \| u \|_{H_0}^2 \leq C.
\]

(3.39)

Observe, \( \nu_1 \sim m_1 \leq 1 \) for all \( \alpha \in (0, 1] \) and \( \omega \in (0, 1] \).

Let \( \bar{R} > 0 \). For all \( \zeta_0 \in \mathcal{H}_0 \) with \( \| \zeta_0 \|_{H_0} \leq \bar{R} \), the upper-bound in (3.33) reads

\[
\Psi(\zeta_0) \leq C(R^2 + \bar{R} + R^p + 2\bar{R}).
\]

(4.40)

Hence, for all \( \bar{R} > 0 \), there exists \( R > 0 \) such that, for all \( \zeta_0 \in \mathcal{H}_0 \) with \( \| \zeta_0 \|_{H_0} \leq \bar{R} \), then \( \Psi(\zeta_0) \leq R \).

From the lower-bound in (3.32), we immediately see that \( \sup_{\tau \geq 0} \Psi(\zeta(t)) \geq -2c_2 - 2c_4 \). By proposition 3.13, there exists \( t_0 = t_0(B) > 0 \), such that for all \( t \geq t_0 \),

\[
\Psi(\zeta(t)) \leq \sup_{\zeta \in \mathcal{H}_0} \{ \Psi(\zeta) : \nu_1 \| \zeta \|_{H_0}^2 \leq 2C \}.
\]

Thus, there is \( R_0 > 0 \) such that, for all \( t \geq t_0 \) and for all \( \zeta_0 \in \mathcal{H}_0 \) with \( \| \zeta_0 \|_{H_0} \leq \bar{R} \),

\[
\| \mathcal{S}_\alpha(t_0) \zeta_0 \|_{H_0} \leq R_0.
\]

(3.41)

By definition, the set \( \mathcal{B}_0 \) in (3.29) is closed and bounded in \( \mathcal{H}_0 \). The inequality in (3.41) implies that \( \mathcal{B}_0 \) is absorbing: given any nonempty bounded subset \( B \) of \( \mathcal{H}_0 \), there is a \( t_0 \geq 0 \) depending on \( B \) in which, for all \( t \geq t_0 \), \( \mathcal{S}_\alpha(t)B \subseteq \mathcal{B}_0 \). Consequently, since \( \mathcal{B}_0 \) is bounded, \( \mathcal{B}_0 \) is also positively invariant under the semiflow \( S_\alpha \). This completes the proof of the dissipation of \( \mathcal{S}_\alpha \) for all \( \alpha \in [0, 1] \).

3.4. Global attractors

In this section we prove
Theorem 3.15. The semiflow $S_\alpha$ generated by the mild solutions of problem $P_\alpha$, $\alpha \in [0, 1]$, admits a global attractor $A_\alpha$ in $\mathcal{H}_0$. The global attractor is invariant under the semiflow $S_\alpha$ (both positively and negatively) and attracts all nonempty bounded subsets of $\mathcal{H}_0$ precisely.

1. For each $t \geq 0$, $S_\alpha(t)A_\alpha = A_\alpha$, and
2. For every nonempty bounded subset $B$ of $\mathcal{H}_0$,

$$\lim_{t \to \infty} \text{dist}_{\mathcal{H}_0}(S_\alpha(t)B, A_\alpha) := \limsup_{t \to \infty} \inf_{\xi \in B} \|S_\alpha(t)\xi - \xi\|_{\mathcal{H}_0} = 0.$$ 

The global attractor is unique and given by

$$A_\alpha := \omega(B_0) = \bigcap_{t \geq 0} \bigcup_{s \geq t} S_\alpha(s)B_0^{\mathcal{H}_0}.$$ 

Furthermore, $A_\alpha$ is the maximal compact invariant subset in $\mathcal{H}_0$.

In the previous section it was shown that the semiflow generated by the mild solutions of problem $P_\alpha$, $\alpha \in [0, 1]$, admits a bounded absorbing set $B_0$ in $\mathcal{H}_0$. According to the standard references on the asymptotic behavior of dissipative dynamical systems (see e.g. [1, 42]), it suffices to show that the semiflows are precompact, or decompose into decaying to zero and precompact parts. We already know the following: For each $\alpha \in [0, 1]$ and for any $t_0 > 0$, the set

$$\bigcup_{t \geq t_0} S_\alpha(t)B_0$$

is bounded in $D(A_\alpha^{1/\gamma})$, (3.42)

where $\gamma = 1$ if $\alpha > 0$ and $\gamma = 2$ if $\alpha = 0$. Equation (3.42) can be deduced from lemma 3.14 and remark 3.8. However, due to the complicated nature of the domain of the operator $A_\alpha$, we do not know that the solutions to problem $P_\alpha$ regularize into precompact trajectories (see (3.16)). The reason for this being the first component of the trajectory does not necessarily regularize into $H^{1+\rho}(\Omega)$, for some $\rho > 0$, of course, is compact in $H^\rho(\Omega)$. Keep in mind the operator $A_\alpha$ does not possess compact resolvent, and, additionally, we do not have a suitable $H^\rho$-elliptic regularity estimate to aid in producing additional smoothness.

To partially remedy this situation, we prove the following:

Lemma 3.16. Let $W_\alpha = (w_{1,n}, w_{2,n}, w_{3,n}, w_{4,n})$ be a bounded sequence in $D(A_\alpha^{1/\gamma})$, where $\gamma = 1$ if $\alpha > 0$ and $\gamma = 2$ if $\alpha = 0$. Then the sequences $\{w_{2,n}\}$ and $\{w_{4,n}\}$ are precompact in $L^2(\Omega)$ and $L^2(\Gamma)$, respectively. Moreover, we can identify $w_{4,n}$ with the trace of $w_{2,n}$, i.e. $w_{4,n} = w_{2,n}|\Gamma$.

Proof. Let $\Phi_\alpha = (\phi_{1,n}, \phi_{2,n}, \phi_{3,n}|\Gamma, \phi_{4,n})$ be a bounded sequence in $\mathcal{H}_0$ such that $A_\alpha^{1/\gamma}W_\alpha = \Phi_\alpha$. For the case $\alpha > 0$, $\gamma = 1$, this immediately implies $w_{2,n} = \phi_{1,n}$ and $w_{4,n} = \phi_{3,n}|\Gamma = w_{2,n}|\Gamma$, which are bounded sequences in $H^1(\Omega)$ and $H^1(\Gamma)$, respectively, hence precompact in $L^2(\Omega)$ and $L^2(\Gamma)$, respectively.

Now we assume $\alpha = 0$, and take $\gamma = 2$. We write

$$W_\alpha = A_\alpha^{-1/2}\Phi_\alpha = \frac{1}{\pi^2} \int_0^\infty \lambda^{-1/2}R(\lambda, A_0)\Phi_\alpha d\lambda.$$ (3.43)

For $\lambda > 0$, consider $U_\alpha(\lambda) = R(\lambda, A_0)\Phi_\alpha$. Then by solving the resolvent equation we see that $U_\alpha(\lambda) = (u_{\alpha}, v_\alpha, u_{\alpha}|\Gamma, v_{\alpha}|\Gamma)$, where
\[ u_n = \frac{v_n + \phi_{l_n}}{\lambda} \]

and \( v_n \) solves, for all \( f \in H^1(\Omega) \cap H^1(\Gamma) \),

\[
\left( \lambda + 1 + \frac{1}{\lambda} \right) (\langle v_n, f \rangle_{L^2(\Omega)} + \langle v_n, f \rangle_{L^2(\Gamma)}) + \left( \omega + 1 + \frac{1}{\lambda} \right) (\nabla v_n, \nabla f)_{L^2(\Omega)} + \frac{1}{\lambda} (\nabla v_n, \nabla f)_{L^2(\Gamma)}
\]

\[
= -\frac{1}{\lambda} (\nabla \phi_{l_n}, \nabla f)_{L^2(\Omega)} - \frac{1}{\lambda} (\phi_{l_n}, f)_{L^2(\Omega)} - \frac{1}{\lambda} (\nabla \phi_{l_n}, \nabla f)_{L^2(\Gamma)} + \frac{1}{\lambda} (\phi_{l_n}, f)_{L^2(\Gamma)} + \langle \phi_{n,n}, f \rangle_{L^2(\Gamma)}.
\]

From (3.44) by taking \( f = v_n \) we can deduce that

\[
\|v_n\|_{H^1(\Omega)}, \|v_n\|_{H^1(\Gamma)} \ll \|\Phi_n\|_{H_0^1},
\]

\[
\|v_n\|_{H^1(\Omega)} \leq \frac{C}{\lambda^{1/2}} \|\Phi_n\|_{H_0^1},
\]

\[
\|v_n\|_{L^2(\Omega)} \leq \frac{1}{\lambda} \|\Phi_n\|_{H_0^1}.
\]

Using (3.46) and (3.47), by interpolation we have, for all \( \theta \in (0, 1) \),

\[
\|v_n\|_{H^{1-\theta}(\Omega)} \leq C \|v_n\|_{H^{1}(\Omega)} \|v_n\|_{L^2(\Gamma)} \leq C \lambda^{-\theta/1/2} \|\Phi_n\|_{H_0^1},
\]

and from the trace theorem we have, for all \( \theta \in (\frac{1}{2}, 1) \),

\[
\|v_n\|_{H^{1-\theta}(\Gamma)} \leq C \lambda^{-\theta/1/2} \|\Phi_n\|_{H_0^1}.
\]

Now writing \( v_n = v_0(\lambda) \) to denote the dependence on \( \lambda \), we can write using (3.43) that

\[
w_{2_n} = \frac{1}{\pi i} \int_0^\infty \lambda^{-1/2} v_0(\lambda) d\lambda \quad \text{and} \quad w_{4_n} = \frac{1}{\pi i} \int_0^\infty \lambda^{-1/2} R(\lambda, A_0)v_n(\lambda) d\lambda,
\]

so long as these integrals converge in \( L^2(\Omega) \) and \( L^2(\Gamma) \), respectively. Indeed, by using (3.48), (3.49), and (3.45) we get, for all \( \theta \in (0, 1) \),

\[
\|w_{2_n}\|_{H^{1-\theta}(\Omega)} \leq \int_0^1 \lambda^{-\theta/2} \|\Phi_n\|_{H_0^1} d\lambda + C \int_1^\infty \lambda^{-\theta/2-1} \|\Phi_n\|_{H_0^1} d\lambda \leq C \|\Phi_n\|_{H_0^1},
\]

and, for all \( \theta \in (\frac{1}{2}, 1) \),

\[
\|w_{4_n}\|_{H^{1-\theta}(\Gamma)} \leq \int_0^1 \lambda^{-\theta/2} \|\Phi_n\|_{H_0^1} d\lambda + C \int_1^\infty \lambda^{-\theta/2-1} \|\Phi_n\|_{H_0^1} d\lambda \leq C \|\Phi_n\|_{H_0^1}.
\]

By taking any \( \theta \in (\frac{1}{2}, 1) \), this proves that the integrals in (3.50) converge, and moreover it allows us to identify \( w_{4_n} = w_{2_n} \mid \Gamma \). Furthermore, since \( H^\theta \) is compactly embedded in \( L^2 \) for all \( \theta > 0 \), the compactness claim is proved.
Proof of theorem 3.15 To show the existence of a family of global attractors in $\mathcal{H}_0$, we appeal to [13, theorem A.1] (or also see, for example, [29, section 3.2] or [32, section 2.7]). Accordingly, we only need to show that there exists a time $T > 0$, a constant $0 < \nu < 1$ and a pre-compact pseudo-metric $\eta$ on $\mathcal{B}_0$, where $\mathcal{B}_0$ is the bounded absorbing set from lemma 3.14, such that

$$
\|S_0(T)\zeta_1 - S_0(T)\zeta_2\|_{\mathcal{H}_0} \leq \nu \|\zeta_1 - \zeta_2\|_{\mathcal{H}_0} + \eta(\zeta_1, \zeta_2) \quad \forall \zeta_1, \zeta_2 \in \mathcal{B}_0.
$$

(3.51)

Let $\zeta_1 = (u_1, v_1, \gamma_1, \delta_1)$ and $\zeta_2 = (u_2, v_2, \gamma_2, \delta_2)$ in $\mathcal{B}_0$ be given, and let $\zeta = (u, v, \gamma, \delta)$. Then $S_0(t)\zeta = (u(t), v(t), u(t)_{|\Gamma}, u(t)_{|\Gamma})$ is the solution of

$$
\begin{cases}
\begin{aligned}
u_{t} - \omega \Delta u_t + u_t - \Delta u &= \bar{f} \quad \text{in } \Omega \times (0, T) \\
\nu_t + \partial_\nu(u + \omega u_t) + u_t - \Delta(\omega u_t + u) + u &= \bar{g} \quad \text{on } \Gamma \times (0, T) \\
(u(0), u_0(0), u_{|\Gamma}(0), u_{|\Gamma}(0)) &= \zeta.
\end{aligned}
\end{cases}
$$

(3.52)

where $\bar{f} = f(u_2(t)) - f(u_1(t))$ and $\bar{g} = g(u_2(t)) - g(u_1(t))$. For now we will assume in addition that $\zeta_1$ and $\zeta_2$ are smooth, i.e. contained in $\mathcal{D}(A_\sigma)$. Then since $S_0(t)\zeta_1$ and $S_0(t)\zeta_2$ are bounded trajectories in $\mathcal{H}_0$ and since $f : H^1(\Omega) \to L^2(\Omega)$ and $g : H^1(\Gamma) \to L^2(\Gamma)$ are locally Lipschitz, we may replace them by globally Lipschitz truncations; hence, by monotone operator theory, (3.52) generates a nonlinear strongly continuous semigroup (for details, see, for instance, [26]). Thus for initial data in $\mathcal{D}(A_\sigma)$ we have $\zeta(t) = S_0(t)\zeta_1 - S_0(t)\zeta_2$ also in $\mathcal{D}(A_\sigma)$ for all $t > 0$, and in particular the solution is classical.

Define the functional on trajectories $\zeta(t) = (u(t), u_1(t), u_2(t), u_{|\Gamma}(t))$ for $t \geq 0$ by

$$
I(t) := \frac{\omega}{2} \|\nabla u(t)\|^2_{L^2(\Omega)} + \frac{\alpha \omega}{2} \|\nabla \nabla u(t)\|^2_{L^2(\Omega)} + \|u(t)\|^2_{L^2(\Omega)} + \|u(t)\|^2_{L^2(\Gamma)} + \langle u(t), u(t) \rangle_{L^2(\Omega)} + \langle u(t), u(t) \rangle_{L^2(\Gamma)}.
$$

By using $u$ as a multiplier in (3.52) and integrating by parts, we get, for almost all $t \geq 0$,

$$
\frac{d}{dt} I + \|u_t\|^2_{L^2(\Omega)} + \|u_{\nu t}\|^2_{L^2(\Gamma)} = \langle \bar{f}, u \rangle_{L^2(\Omega)} + \langle \bar{g}, u \rangle_{L^2(\Gamma)} + \|u_t\|^2_{L^2(\Omega)} + \|u_t\|^2_{L^2(\Gamma)}.
$$

We define also the following energy functional

$$
E(t) := \frac{1}{2} \|S_0(t)\zeta_1 - S_0(t)\zeta_2\|^2_{\mathcal{H}_0} - \frac{1}{2} \|u(t)\|^2_{L^2(\Omega)} + \frac{1}{2} \|u(t)\|^2_{L^2(\Gamma)} + \frac{1}{2} \|u(t)\|^2_{L^2(\Omega)} + \frac{1}{2} \|u(t)\|^2_{L^2(\Gamma)}.
$$

We then set $L = E + dI$, for some $\epsilon > 0$ to be determined. Recalling the formal energy identity (3.18), we can write

$$
\frac{d}{dt} L + \omega \|\nabla u_t\|^2_{L^2(\Omega)} + \alpha \omega \|\nabla \nabla u_t\|^2_{L^2(\Omega)} + \|u_t\|^2_{L^2(\Omega)} + \|u_t\|^2_{L^2(\Gamma)} + \epsilon \|u_t\|^2_{L^2(\Omega)} + \epsilon \|u_t\|^2_{L^2(\Gamma)}
= \epsilon \|u_t\|^2_{L^2(\Omega)} + \epsilon \|u_t\|^2_{L^2(\Gamma)} + \langle u_t, \bar{f} \rangle_{L^2(\Omega)} + \langle u_t, \bar{g} \rangle_{L^2(\Gamma)} + \epsilon \langle u_t, \bar{f} \rangle_{L^2(\Omega)} + \epsilon \langle u_t, \bar{g} \rangle_{L^2(\Gamma)}.
$$

For $\epsilon > 0$ small enough we can write, for each $t \geq 0$,
\[ L \leq \frac{3}{4} \|u\|_{H^2}(\Omega) + \frac{3}{4} \|u\|_{H^2}(\Gamma) + \|u_t\|_{L^2}(\Omega) + \|u_t\|_{L^2}(\Gamma), \]

from which follows

\[ \frac{d}{dt} L + cL + \omega \| \nabla u_t \|_{L^2}(\Omega) + \alpha \omega \| \nabla u_t \|_{H^1}(\Omega) \]
\[ + (1 - 2\epsilon) \|u\|_{H^2}(\Omega) + (1 - 2\epsilon) \|u\|_{H^2}(\Gamma) + \frac{\epsilon}{8} \|u\|_{H^2}(\Omega) + \frac{\epsilon}{8} \|u\|_{H^2}(\Gamma) \]
\[ \leq \langle u, \tilde{f} \rangle_{L^2(\Omega)} + \langle u, f \rangle_{L^2(\Gamma)} + \epsilon \langle u, \tilde{f} \rangle_{L^2(\Omega)} + \epsilon \langle u, g \rangle_{L^2(\Gamma)}. \]

Recalling that \( f \) and \( g \) are locally Lipschitz and that \( u_1, u_2 \) are bounded in \( H^1(\Omega) \) and \( H^1(\Gamma) \), we have,

\[ \| \tilde{f} \|_{L^2(\Omega)} = \| f(u_1) - f(u_2) \|_{L^2(\Omega)} \leq C \| u_1 - u_2 \|_{H^0(\Omega)} = C \| u \|_{H^0(\Gamma)}, \]

and likewise \( \| g \|_{L^2(\Gamma)} \leq C \| u \|_{H^0(\Gamma)} \). This is sufficient to obtain, for almost all \( t \geq 0 \),

\[ \frac{d}{dt} L + cL + \omega \| \nabla u_t \|_{L^2}(\Omega) + \alpha \omega \| \nabla u_t \|_{H^1}(\Omega) \]
\[ + (1 - 2\epsilon) \|u\|_{H^2}(\Omega) + (1 - 2\epsilon) \|u\|_{H^2}(\Gamma) + \frac{\epsilon}{8} \|u\|_{H^2}(\Omega) + \frac{\epsilon}{8} \|u\|_{H^2}(\Gamma) \]
\[ \leq \langle u, \tilde{f} \rangle_{L^2(\Omega)} + \langle u, g \rangle_{L^2(\Gamma)} + C \epsilon \| u \|_{H^2(\Omega)} + C \epsilon \| u \|_{H^2(\Gamma)}. \]

For the remaining terms, we have the more precise estimates

\[ \langle u, \tilde{f} \rangle_{L^2(\Omega)} \leq \| u \|_{L^2(\Omega)} \| f(u_1) - f(u_2) \|_{L^2(\Omega)} \]
\[ \leq \| u \|_{L^2(\Omega)} \| u \|_{L^2(\Omega)} \| 1 + |u|^2 + |u|^2 \|_{L^2(\Omega)} \]
\[ \leq C \| u \|_{H^0(\Omega)} \| u \|_{L^2(\Omega)} (1 + \| u \|_{L^2(\Omega)} + \| u \|_{L^2(\Omega)}) \]
\[ \leq C \| u \|_{H^0(\Omega)} \| u \|_{L^2(\Omega)}, \]

and similarly, we find

\[ \langle u, g \rangle_{L^2(\Gamma)} \leq \| u \|_{L^2(\Gamma)} \| u \|_{L^2(\Gamma)} \| 1 + |u|^p - 1 + |u|^p - 1 \|_{L^2(\Gamma)} \]
\[ \leq C \| u \|_{H^0(\Gamma)} \| u \|_{L^2(\Gamma)} (1 + \| u \|_{L^2(\Gamma)} + \| u \|_{L^2(\Gamma)}) \]
\[ \leq C \| u \|_{H^0(\Gamma)} \| u \|_{L^2(\Gamma)}, \]

where \( H^{1/2}(\Gamma) \hookrightarrow L^2(\Gamma) \) by the Sobolev embedding theorem and \( H^1(\Omega) \hookrightarrow H^{1/2}(\Gamma) \) by the trace theorem. Thus, for \( \epsilon > 0 \) small enough we can conclude

\[ \frac{d}{dt} L + cL \leq C \| u \|_{L^2(\Omega)} + C \| u \|_{L^2(\Gamma)} \]

where upon integration we deduce, for all \( t \geq 0 \),

\[ L(t) \leq e^{-\epsilon t} L(0) + C \int_0^t (\| u(s) \|_{L^2(\Omega)} + \| u(s) \|_{L^2(\Gamma)}) ds. \]
On the other hand, we have from the very definition of \(L\)
\[
\frac{1}{4} \| S_\alpha(t) \zeta_1 - S_\alpha(t) \zeta_2 \|^2_{H_\alpha} \leq L(t) \leq (1 + \omega) \| S_\alpha(t) \zeta_1 - S_\alpha(t) \zeta_2 \|^2_{H_\alpha}
\]
so it follows that, for all \(t \geq 0\),
\[
\| S_\alpha(t) \zeta_1 - S_\alpha(t) \zeta_2 \|^2_{H_\alpha} \leq C e^{-\delta t} \| \zeta_1 \|^2_{H_\alpha} + C \alpha \sup_{s \in [0,t]} (\| u(s) - u_2(s) \|^2_{L^2} + \| u(s) - u_2(s) \|^2_{L^2(t)}).\]

Now by continuity of the semigroup, this inequality also holds for any \(\zeta_1, \zeta_2 \in B_{\alpha}\), since the domain of the generator is dense in \(H_\alpha\). Moreover, the metric
\[
\eta(\zeta_1, \zeta_2) := \sup_{\tau \in [0,t]} (\| u_1(\tau) - u_2(\tau) \|^2_{L^2} + \| u_1(\tau) - u_2(\tau) \|^2_{L^2(t)})^{1/2}
\]
is precompact in \(B_\alpha\) since \(H^1\) is compact in \(L^2\). Therefore (3.51) is satisfied. The proof of theorem 3.15 is now complete. \(\square\)

The dimension of these global attractors is explored further once we obtain the results in a later section. The next section contains a simple continuity result for the family of global attractors.

3.5. Continuity properties of the global attractors

In this section we aim to prove, in a sense to be made more precise shortly, that
\[
A_\alpha \to A_0 \text{ in } H_0 \text{ as } \alpha \to 0.
\]

Following, for example [39, section 10.8], the perturbation induced by the parameter \(\alpha > 0\) to problem \(P_0\), is termed regular because both classes of problem \(P\) lie in the same ‘standard energy’ phase space; in particular, the family of global attractors, \(\{ A_\alpha \}_{\alpha \in [0,1]} \), lies in \(H_0\). We will utilize [39, theorem 10.16].

**Proposition 3.17.** Assume that for \(\varepsilon \in [0,\varepsilon_0]\) the semigroups \(S_\varepsilon\) each admit a global attractor \(A_\varepsilon\) and that there exists a bounded set \(X\) such that
\[
\bigcup_{\varepsilon \in (0,\varepsilon_0)} A_\varepsilon \subset X.
\]

If in addition the semigroup \(S_\varepsilon\) converges to \(S_0\) in the sense that, for each \(t > 0\), \(S_\varepsilon(t)x \to S_0(t)x\) uniformly on bounded subsets \(Y\) of the phase space \(H\), i.e.
\[
\sup_{x \in Y} \| S_\varepsilon(t)x - S_0(t)x \|_{H} \to 0 \text{ as } \varepsilon \to 0,
\]
then
\[
\text{dist}(A_\varepsilon, A_0) \to 0 \text{ as } \varepsilon \to 0.
\]

We will show, with a fair amount of ease, that the family of global attractors for problem \(P_\alpha\), for all \(\alpha \in [0,1]\), are upper-semicontinuous in the topology of \(H_0\). We now arrive at our first result.

**Lemma 3.18.** Let \(B\) be a bounded set in \(H_0\) and \(T > 0\). There exists a constant \(M = M(\|B\|_{H_\alpha}, T) > 0\) such that for all \(\zeta_0 \in B\) and for all \(t \in [0,T]\), there holds, for all \(\alpha \in (0,1]\),

1196
\[ \|S_\alpha(t)z_0 - S_\beta(t)z_0\|_{H_\alpha} \leq \sqrt{\alpha}M. \]  

**Proof.** Let \( B \) be a bounded set on \( H_\alpha, T > 0, \) and \( \alpha \in (0, 1]. \) Let \( \zeta_0 = (u_0, u_1, \gamma_0, \gamma_1) \in B. \) For \( t > 0, \) let
\[
\zeta(t) = (u(t), u_1(t), u_{11}(t), u_{111}(t)) \quad \text{and} \quad \zeta(t) = (u^2(t), u^2_1(t), u^2_{11}(t), u^2_{111}(t)),
\]
denote the corresponding global solutions of problem \( P_\alpha \) and problem \( P_0, \) respectively, on \([0, T],\) both with the (same) initial data \( \zeta_0.\) For all \( t \in (0, T], \) set
\[
\zeta(t) := \zeta^1(t) - \zeta^2(t) = (u^1(t), u^1_1(t), u^1_{11}(t)) - (u^2(t), u^2_1(t), u^2_{11}(t)) =: (\tilde{u}(t), \tilde{u}_1(t), \tilde{u}_{11}(t), \tilde{u}_{111}(t)).
\]
Then \( \zeta \) and \( \tilde{u} \) satisfy the equations
\[
\begin{aligned}
\tilde{u} - \omega \Delta \tilde{u} + \tilde{u}_1 - \Delta \tilde{u} + \tilde{u} + f(u) - f(u^2) &= 0 \quad \text{in} \quad (0, \infty) \times \Omega \\
\tilde{u} + \partial_n(\tilde{u} + \tilde{u}_1) - \Delta \tilde{u} + \tilde{u} + g(u) - g(u^2) &= \alpha \omega \Delta \tilde{u}_1^{11} \quad \text{on} \quad (0, \infty) \times \Gamma \\
\tilde{u}(0) &= 0 \quad \text{at} \quad \{0\} \times \Omega.
\end{aligned}
\]
To obtain (3.53), we now only need to follow the proof of proposition 3.11: after multiplying the equation (3.54) by \( 2\tilde{u}_v, \) in \( L^2(\Omega), \) we estimate the new product to arrive at
\[
-2\alpha \omega (\Delta \tilde{u}_1, \tilde{u}_v)_{L^2(\Gamma)} \leq \alpha \omega \|\nabla \nabla \tilde{u}_v\|_{L^2(\Gamma)} + \alpha \omega \|\nabla \nabla \tilde{u}_v\|_{L^2(\Gamma)} \leq \alpha Q_{\|B\|_{H_\alpha}} + \alpha \omega \|\tilde{u}_v\|_{H^4(\Gamma)}.
\]
The result readily follows. This finishes the proof.

**Remark 3.19.** The above result (3.53) establishes that, on compact time intervals, the difference between trajectories of problem \( P_\alpha, \alpha \in (0, 1], \) and problem \( P_0, \) originating from the same initial data in \( B \subset H_\alpha, \) can be controlled, explicitly, in terms of the perturbation parameter \( \alpha. \)

The well-known upper-semicontinuity result in proposition 3.17 now follows for our family of global attractors.

**Theorem 3.20.** The family of global attractors \( \{A_\alpha\}_{\alpha \in (0, 1]} \) is upper-semicontinuous in the topology of \( H_\alpha; \) precisely, there is a constant \( C > 0 \) independent of \( \alpha \) in which there holds
\[
dist_{H_\alpha}(A_\alpha, A_\beta) \leq \sqrt{\alpha} C.
\]

### 3.6. Weak exponential attractors

This section is motivated by [36, section 4]. In this section we show the existence of a so-called weak exponential attractor. We seek a weak exponential attractor (in place of the standard one) for two central reasons. First, we recall the complicated nature of the domain of the operator associated with the abstract Cauchy problem means the solution operators may not admit a compact absorbing set in the standard energy phase space. The second reason involves the presence of the dynamic flux term \( \partial_n u, \) in our boundary condition. Recently, works such as [8, 18–21, 27, 33] are able to establish the existence of an exponential attractor for wave
equations with dynamic boundary conditions with the use of suitable $H^2$-elliptic regularity estimates. Because of the dynamic flux term $\partial_u n$, such estimates are not available here.

Here we define the space

$$\mathcal{H}_{-1} := L^2(\Omega) \times H^{-1}(\Omega) \times L^2(\Gamma) \times H^{-1}(\Gamma)$$

endowed with the canonical norm, and there holds

$$\mathcal{H}_0 \hookrightarrow \mathcal{H}_{-1},$$

with continuous injections.

**Theorem 3.21.** For each $\alpha \in [0, 1]$, the semiflow $S_\alpha$ generated by the weak solutions of problem $P$, admits a weak exponential attractor $M_{-1, \alpha}$ that satisfies:

1. $M_{-1, \alpha}$ is bounded in $\mathcal{H}_0$ and compact in $\mathcal{H}_{-1}$.
2. $M_{-1, \alpha}$ is positively invariant; i.e. for all $t \geq 0$, $S_\alpha(t)M_{-1, \alpha} \subseteq M_{-1, \alpha}$.
3. $M_{-1, \alpha}$ attracts bounded subsets of $\mathcal{H}_0$ exponentially with the metric of $\mathcal{H}_{-1}$; i.e. there exists $\nu > 0$ and $Q$ such that, for every bounded subset $B \subseteq \mathcal{H}_0$ and for all $t \geq 0$,

$$\text{dist}_{\mathcal{H}_0}(S_\alpha(t)B, M_{-1, \alpha}) \leq Q(\|B\|_{\mathcal{H}_0})e^{-\nu t}.$$  

4. $M_{-1, \alpha}$ possesses finite fractal dimension in $\mathcal{H}_{-1}$; i.e.

$$\dim_f(M_{-1, \alpha}, \mathcal{H}_{-1}) := \limsup_{r \to 0} \frac{\ln \mu_{\mathcal{H}_0}(M_{-1, \alpha}, r)}{-\ln r} < \infty,$$

where $\mu_{\mathcal{H}_0}(M_{-1, \alpha}, r)$ denotes the minimum number of balls of radius $r$ from $\mathcal{H}_{-1}$ required to cover $M_{-1, \alpha}$.

**Corollary 3.22.** In the topology of $\mathcal{H}_{-1}$, the global attractor possesses finite fractal dimension. Indeed, there holds

$$\dim_f(A, \mathcal{H}_{-1}) \leq \dim_f(M_{-1, \alpha}, \mathcal{H}_{-1}) \leq C,$$

for some constant $C > 0$, independent of $\alpha$.

**Remark 3.23.** Naturally, after demonstrating the existence of global attractors for problem $P$, the next question is whether the global attractors are finite dimensional, in the standard phase space $\mathcal{H}_0$. Unfortunately, we cannot yet conclude that the fractal dimension of $M_{-1, \alpha}$ (nor $A_\alpha$) in $\mathcal{H}_0$ is finite.

The proof of theorem 3.21 follows from the application of an abstract result modified only to suit our needs here (for further reference, see for example, [14, 15, 22], and also the reference associated with remark 3.29 below).

**Proposition 3.24.** Let $\mathcal{H}_0$ and $\mathcal{H}_{-1}$ be Hilbert spaces such that the embedding $\mathcal{H}_0 \hookrightarrow \mathcal{H}_{-1}$ is compact. Let $S = (S(t))_{t \geq 0}$ be a semiflow on $\mathcal{H}_0$. Assume the following hypotheses hold:

(H1) There exists a bounded absorbing set $B_0 \subset \mathcal{H}_0$ which is positively invariant for $S(t)$. More precisely, there exists a time $t_0 > 0$ (possibly depending on the radius of $B_0$) such that, for all $t \geq t_0$,

$$S(t)B_0 \subset B_0.$$

(H2) There is $t^* \geq t_0$ such that the map $S(t^*)$ admits the decomposition, for all $\zeta_01, \zeta_02 \in B_0$. 

where, for some constants \( \kappa = \kappa(t^*) \in (0, \frac{1}{2}) \) and \( \Lambda = \Lambda(t^*) \geq 0 \), the following hold:

\[
\|L(\zeta_{01}, \zeta_{02})\|_{H^{-1}} \leq \kappa \|\zeta_{01} - \zeta_{02}\|_{H^{-1}} \tag{3.58}
\]

and

\[
\|K(\zeta_{01}, \zeta_{02})\|_{H^0} \leq \Lambda \|\zeta_{01} - \zeta_{02}\|_{H^{-1}}. \tag{3.59}
\]

(H3) The map

\[
(t, \zeta_0) \mapsto S(t)\zeta : [t^*, 2t^*] \times B_0 \to B_0 \tag{3.60}
\]

is Lipschitz continuous on \( B_0 \) in the topology of \( H^{-1} \).

Then the semiflow \( S \) admits an exponential attractor \( M_{-1} \) in \( B_0 \).

We now show that the hypotheses (H2) and (H3) hold for the semiflow \( \alpha S \) generated by the mild solutions of problem \( \alpha P \) for the spaces given in (3.56). Of course, the first hypothesis (H1) was already shown in lemma 3.14.

Before we can show (H2) and (H3), we will need to utilize an ‘eventual’ local Lipschitz continuity property of the semiflow in the weaker energy space \( H^{-1} \). The following proposition is based on [36, proposition 2.2].

**Proposition 3.25.** Let \( \zeta_{01}, \zeta_{02} \in B_0 \) (the bounded absorbing set in \( H \)). Any two (global) mild solutions, \( \zeta_1(t) \) and \( \zeta_2(t) \), to problem \( \alpha P \), \( \alpha \in [0, 1] \), corresponding to the initial data \( \zeta_{01} \) and \( \zeta_{02} \), respectively, satisfy for all \( t \geq \delta \), for any \( \delta > 0 \),

\[
\|\zeta_1(t) - \zeta_2(t)\|_{H^{-1}} \leq C_\omega e^{Ct}\|\zeta_{01} - \zeta_{02}\|_{H^{-1}} \tag{3.61}
\]

for some constants \( C_\omega > 0 \) depending on \( \omega \in (0, 1] \) like \( C_\omega \sim \omega^{-1/2} \), and \( C = C(R_0) > 0 \), depending on the (fixed) radius of \( B_0 \).

**Proof.** Let

\[
\chi(t) := \int_0^t \bar{u}(\tau) d\tau. \tag{3.62}
\]

Integrating equations (3.22)–(3.22) over \((0, t)\), we find the transformed equations

\[
\bar{\chi}_t(t) - \omega \Delta \bar{\chi}(t) + \bar{\chi}_t(t) - \Delta \bar{\chi}(t) + \bar{\chi}(t)
+ \int_0^t (f(\bar{u}(\tau)) - f(\bar{u}^2(\tau))) d\tau = 0 \quad \text{in} \quad \Omega, \tag{3.63}
\]

and

\[
\bar{\chi}_t(t) + \bar{\partial}_n(\omega \bar{\chi}_t(t) + \bar{\chi}(t)) - \alpha \omega \Delta \bar{\chi}_t(t) + \bar{\chi}_t(t) - \Delta \bar{\chi}(t) + \bar{\chi}(t)
+ \int_0^t (g(\bar{u}(\tau)) - g(\bar{u}^2(\tau))) d\tau = 0 \quad \text{on} \quad \Gamma. \tag{3.64}
\]

Since the solutions \( \zeta_1 \) and \( \zeta_2 \) satisfy (3.16), then \( \tilde{\zeta} = (\bar{\chi}, \bar{\chi}_t, \bar{\chi}_{t,t}) \in C([0, \infty); H^{-1}). \) Hence, each term of (3.63)–(3.64) when taken in the \( L^2 \) product with \( \bar{\chi}_t = \bar{u} \in C([0, \infty); H^0(\Omega)) \) is well-defined. For notational ease, we proceed to denote...
\[ \mathcal{F}(t) := \int_0^t (f(u'(\tau)) - f(u^2(\tau)))d\tau, \]

and

\[ \mathcal{G}(t) := \int_0^t (g(u'(\tau)) - g(u^2(\tau)))d\tau. \]

Observe

\[ \int_0^t (f(u'(\tau)) - f(u^2(\tau)), \chi(t)) \in L^2(\Omega) \quad \Rightarrow \quad \langle \mathcal{F}(t), \chi(t) \rangle_{L^2(\Omega)} = -\langle \mathcal{F}(0), \chi(0) \rangle_{L^2(\Omega)} + \frac{d}{dt} \langle \mathcal{F}(t), \chi(t) \rangle_{L^2(\Omega)}, \quad (3.65) \]

and similarly,

\[ \int_0^t (g(u'(\tau)) - g(u^2(\tau)), \chi(t)) \in L^2(\Gamma) \quad \Rightarrow \quad \langle \mathcal{G}(t), \chi(t) \rangle_{L^2(\Gamma)} = -\langle \mathcal{G}(0), \chi(0) \rangle_{L^2(\Gamma)} + \frac{d}{dt} \langle \mathcal{G}(t), \chi(t) \rangle_{L^2(\Gamma)}, \quad (3.66) \]

Now we multiply (3.63)–(3.64) by \( \chi_t \) in \( L^2(\Omega) \) and \( L^2(\Gamma) \), respectively, combining the results to find

\begin{align*}
\frac{d}{dt} \left\{ \| \nabla \chi \|^2_{H^2(\Omega)} + \| \nabla \chi \|^2_{H^2(\Gamma)} + \| \chi_t \|^2_{L^2(\Gamma)} \right. \\
+ 2\langle \mathcal{F}(t), \chi(t) \rangle_{L^2(\Omega)} + 2\langle \mathcal{G}(t), \chi(t) \rangle_{L^2(\Gamma)} \\
+ 2\alpha \omega \| \nabla \nabla \chi \|^2_{L^2(\Omega)} + \| \chi_t \|^2_{L^2(\Gamma)} + 2\| \chi \|^2_{L^2(\Gamma)} \\
= 2\langle \mathcal{F}(t), \chi(t) \rangle_{L^2(\Omega)} + 2\langle \mathcal{G}(t), \chi(t) \rangle_{L^2(\Gamma)}. \quad (3.67) \end{align*}

The identity (3.67) readily becomes the differential inequality, which holds for almost all \( t \geq 0 \),

\begin{align*}
\frac{d}{dt} \left\{ \| \nabla \chi \|^2_{H^2(\Omega)} + \| \nabla \chi \|^2_{H^2(\Gamma)} + \| \chi_t \|^2_{L^2(\Gamma)} \right. \\
+ 2\langle \mathcal{F}(t), \chi(t) \rangle_{L^2(\Omega)} + 2\langle \mathcal{G}(t), \chi(t) \rangle_{L^2(\Gamma)} \\
\leq 2\langle \mathcal{F}(t), \chi(t) \rangle_{L^2(\Omega)} + 2\langle \mathcal{G}(t), \chi(t) \rangle_{L^2(\Gamma)}. \quad (3.68) \end{align*}

Integrating (3.68) over \((0, t)\) yields, for all \( t \in (0, T) \),

\begin{align*}
\| \nabla \chi(t) \|^2_{H^2(\Omega)} & \leq \| \nabla \chi(0) \|^2_{H^2(\Omega)} + 2\langle \mathcal{F}(t), \chi(t) \rangle_{L^2(\Omega)} + 2\| \nabla \chi \|^2_{L^2(\Gamma)} + 2\langle \mathcal{G}(t), \chi(t) \rangle_{L^2(\Gamma)} \\
& \quad + 2 \int_0^t \langle \mathcal{F}(\tau), \chi(\tau) \rangle_{L^2(\Omega)}d\tau + 2 \int_0^t \langle \mathcal{G}(\tau), \chi(\tau) \rangle_{L^2(\Gamma)}d\tau. \quad (3.69) \end{align*}

Observe, using the definition of \( \hat{\zeta} \), the \( \mathcal{H}_0 \) and \( \mathcal{H}_{-1} \) norms, and the transformation (3.62),

\begin{align*}
\| \hat{\zeta} \|^2_{\mathcal{H}_0^2} &= \| (\chi(0), \chi_t(0), \chi_{tt}(0)) \|^2_{\mathcal{H}_0^2} \\
&= \| a_0 \|^2_{L^2(\Omega)} + \| \gamma_0 \|^2_{L^2(\Gamma)} \\
&\leq \| \zeta_0 \|^2_{\mathcal{H}_{-1,4}}. \quad (3.70) \end{align*}
Estimating the products yields (we recall from lemma 2.6 that $f$ and $g$ are Lipschitz on the absorbing set $B_0$),

$$2|\langle \bar{F}(t), \bar{\chi}(t) \rangle_{L^2(\Omega)}| \leq 2 \int_0^t |\langle f(u^1(\tau)) - f(u^2(\tau)), \bar{\chi}(t) \rangle_{L^2(\Omega)}| \, d\tau$$

$$\leq C \int_0^t \|u(\tau)\|_{L^2(\Omega)} \|\bar{\chi}(t)\|_{L^2(\Omega)} \, d\tau$$

$$\leq C \int_0^t \|a(\tau)\|_{L^2(\Omega)} \, d\tau + \frac{1}{4} \|\bar{\chi}(t)\|_{H^s}^2$$

$$= C \int_0^t \|\bar{\chi}(\tau)\|_{L^2(\Omega)} \, d\tau + \frac{1}{4} \|\bar{\chi}(t)\|_{H^s}^2$$

$$\leq C \int_0^t \|\hat{\chi}(\tau)\|_{H^s}^2 \, d\tau + \frac{1}{4} \|\hat{\chi}(t)\|_{H^s}^2,$$  \hspace{1cm} (3.71)

and now in a very similar fashion,

$$2|\langle \bar{G}(t), \bar{\chi}(t) \rangle_{L^2(\Gamma)}| \leq C \int_0^t \|\hat{\chi}(\tau)\|_{H^s}^2 \, d\tau + \frac{1}{4} \|\hat{\chi}(t)\|_{H^s}^2.$$  \hspace{1cm} (3.72)

(We should remark that since the data belongs to the absorbing set which has a fixed radius $R_0$, we use the constant $C > 0$ in place of the function $Q(R)$ which was used above.) We also find,

$$2|\langle \bar{F}(\tau), \bar{\chi}(\tau) \rangle_{L^2(\Omega)}| \leq C \|\bar{u}(\tau)\|_{L^2(\Omega)} \|\bar{\chi}(\tau)\|_{L^2(\Omega)}$$

$$= C \|\bar{\chi}(\tau)\|_{L^2(\Omega)} \|\bar{\chi}(\tau)\|_{L^2(\Omega)}$$

$$\leq C \|\bar{\chi}(\tau)\|_{L^2(\Omega)} \|\bar{\chi}(\tau)\|_{H^s(\Omega)}$$

$$\leq C \|\hat{\chi}(\tau)\|_{H^s}^2,$$  \hspace{1cm} (3.73)

and similarly,

$$2|\langle \bar{G}(\tau), \bar{\chi}(\tau) \rangle_{L^2(\Gamma)}| \leq C \|\hat{\chi}(\tau)\|_{H^s}^2.$$  \hspace{1cm} (3.74)

Thus, (3.69)–(3.73) become

$$\|\hat{\chi}(t)\|_{H^s}^2 + \int_0^t (2\omega \|\bar{\chi}(\tau)\|_{H^s(\Omega)} + 2\|\bar{\chi}(\tau)\|_{H^s(\Omega)}^2) \, d\tau$$

$$\leq 2\|\hat{\chi}_0\|_{H^s}^2 + C \int_0^t \|\hat{\chi}(\tau)\|_{H^s}^2 \, d\tau.$$  \hspace{1cm} (3.75)

First, omitting the positive integral on the left-hand side of (3.75) and applying the integral form of Grönwall’s lemma to the result produces, for all $t \geq 0$,

$$\|\hat{\chi}(t)\|_{H^s}^2 = \|\bar{\chi}(t)\|_{H^s(\Omega)}^2 + \|a(t)\|_{L^2(\Omega)}^2 + \|\bar{\chi}(t)\|_{H^s(\Omega)}^2 + \|a(t)\|_{L^2(\Gamma)}^2$$

$$\leq 2\|\hat{\chi}_0\|_{H^s}^2 e^{Ct}.$$  \hspace{1cm} (3.76)

Then omitting the positive norm from the left-hand side of (3.75) and applying (3.76) to the right-hand side of (3.75), we estimate the integral as
\[
\int_0^t (\omega\|\chi(t)\|_{H^1(\Omega)}^2 + \|\chi(t)\|_{H^2(\Gamma)}^2)\,dt = \int_0^t (\omega\|u(t)\|_{H^1(\Omega)}^2 + \|u(t)\|_{H^2(\Gamma)}^2)\,dt \leq C\|a\|_{L^2_t, L^4}\,e^t. \tag{3.77}
\]

To finish the proof of the claim (3.61), we first write
\[
\|a_1\|_{H^{-1}(\Omega)}^2 + \|a_2\|_{H^{-1}(\Gamma)} = \|\chi_1\|_{H^{-1}(\Omega)}^2 + \|\chi_2\|_{H^{-1}(\Gamma)}^2. \tag{3.78}
\]
To this end we recall from equation (3.63)
\[
\|\chi_1\|_{H_0^1(\Omega)} \leq C(\|\Delta(\omega\chi_1 + \chi)\|_{H^{-1}(\Omega)}^2 + \|\chi_1\|_{H^{-1}(\Omega)}^2 + \|\chi_1\|_{H^{-1}(\Gamma)}^2 + \|\chi_2\|_{H^{-1}(\Gamma)}^2). \tag{3.79}
\]
By definition of the $H^{-1}(\Omega)$ norm
\[
\|\Delta(\omega\chi_1 + \chi)\|_{H^{-1}(\Omega)} = \sup_{\psi \in H_0^1(\Omega)} \|\langle \Delta(\omega\chi_1 + \chi), \psi \rangle_{L^2(\Omega)}\| = \sup_{\|\psi\|_{H_0^1(\Omega)} = 1} \{ |\langle \nabla(\omega\chi_1 + \chi), \nabla\psi \rangle_{L^2(\Omega)}| + |\langle \partial_\alpha(\omega\chi_1 + \chi), \psi \rangle_{L^2(\Omega)}| \}
\leq \|\nabla(\omega\chi_1 + \chi)\|_{L^2(\Omega)} + C\|\partial_\alpha(\omega\chi_1 + \chi)\|_{L^2(\Gamma)}
\leq \|\nabla\chi_1\|_{L^2(\Omega)} + C\|\nabla\chi\|_{L^2(\Gamma)} + C\|\nabla\chi\|_{L^2(\Gamma)}
\leq \|\nabla\chi\|_{L^2(\Omega)} + C\|\nabla\chi\|_{L^2(\Gamma)} + C\|\nabla\chi\|_{L^2(\Gamma)}. \tag{3.80}
\]

The constant $C > 0$ first appearing above is due to the trace embedding $H^1(\Omega) \hookrightarrow L^2(\Gamma)$. In a similar fashion we expand $\|\chi_1\|_{H^{-1}(\Gamma)}$, to find
\[
\|\chi_1\|_{H^{-1}(\Gamma)} \leq C(\|\Delta_\Gamma(\omega\chi_1 + \chi)\|_{H^{-1}(\Gamma)}^2 + \|\partial_\alpha(\omega\chi_1 + \chi)\|_{H^{-1}(\Gamma)}^2 + \|\chi_1\|_{H^{-1}(\Gamma)}^2 + \|\chi_2\|_{H^{-1}(\Gamma)}^2 + \|\mathbb{G}\|_{H^{-1}(\Gamma)}^2). \tag{3.81}
\]
where
\[
\|\Delta_\Gamma(\omega\chi_1 + \chi)\|_{H^{-1}(\Gamma)} \leq \|\nabla_\Gamma u\|_{L^2(\Gamma)} + \|\nabla_\Gamma \chi\|_{L^2(\Gamma)} \tag{3.82}
\]
and (recall, by definition, $\partial_\alpha u = n \cdot \nabla u$)
\[
\|\partial_\alpha(\omega\chi_1 + \chi)\|_{H^{-1}(\Gamma)} \leq C\|\nabla_\Gamma u\|_{L^2(\Gamma)} + C\|\nabla_\Gamma \chi\|_{L^2(\Gamma)}. \tag{3.83}
\]
Combining (3.79)–(3.83), using the fact that both $f$ and $g$ are Lipschitz on $B_0$, then applying (3.76), we now have
\[
\|a(t)\|_{H^{-1}(\Omega)}^2 + \|a(t)\|_{H^{-1}(\Gamma)}^2 \leq C(\|\nabla a(t)\|_{L^2(\Omega)}^2 + \|\nabla_\Gamma a(t)\|_{L^2(\Gamma)}^2) + C\|\mathbb{G}\|_{H^{-1}(\Gamma)}^2. \tag{3.84}
\]

To complete the required bound, it suffices to show that for all $t \geq \delta$ for any $\delta > 0$, there holds
Recall from (3.77) we already know that \( \nabla \bar{u} \in L^2(0, \infty; \mathcal{L}^2(\Omega)) \) and \( \nabla \bar{u} \in L^2(0, \infty; \mathcal{L}^2(\Gamma)) \). In order to improve this result to the bound we seek, our next step is to multiply (3.63) by \(-\Delta(\omega \bar{u}_t + \bar{u}) \) in \( \mathcal{L}^2(\Omega) \) and multiply (3.64) by \(-\Delta_t(\omega \bar{u}_t + \bar{u}) \) in \( \mathcal{L}^2(\Gamma) \) to produce a differential identity which we will integrate on \([\delta, t] \). It is important to note that for \( t > 0 \), the regularity properties of the solutions \( \xi^1, \xi^2 \) given in (3.16) insure these products are well-defined in the \( \mathcal{L}^2 \) sense. Indeed, since \(-\Delta(\omega \bar{u}_t + \bar{u}) \) and \(-\Delta_t(\omega \bar{u}_t + \bar{u}) \) are Lipschitz continuous on \( [0, \infty) \), it immediately follows that, for all \( t > 0 \),

\[
\|\Delta(\omega \bar{u}_t + \bar{u})\|_{\mathcal{L}^2(\Omega)},
\]

and a similar calculation also holds on \( \Gamma \). We write the resulting identity as

\[
\frac{1}{2} \frac{d}{dt} \left\{ \omega \|\nabla \bar{u}_t\|_{\mathcal{L}^2(\Omega)}^2 + 2(\nabla \bar{u}_t, \nabla \bar{u})_{\mathcal{L}^2(\Omega)} + \|\nabla \bar{u}\|_{\mathcal{L}^2(\Omega)}^2 \right\} \\
+ \alpha \omega \|\nabla \bar{u}_t\|_{\mathcal{L}^2(\Gamma)}^2 + 2(\nabla \bar{u}_t, \nabla \bar{u})_{\mathcal{L}^2(\Gamma)} + \|\nabla \bar{u}\|_{\mathcal{L}^2(\Gamma)}^2 \\
+ \|\Delta(\omega \bar{u}_t + \bar{u})\|_{\mathcal{L}^2(\Omega)}^2 + \omega(\nabla \bar{u}_t, \nabla \bar{u})_{\mathcal{L}^2(\Omega)} + \|\nabla \bar{u}\|_{\mathcal{L}^2(\Omega)}^2 \\
+ \|\bar{u}_t + \bar{u} + \bar{u}\|_{\mathcal{L}^2(\Gamma)}^2 + \omega(\nabla \bar{u}_t, \nabla \bar{u})_{\mathcal{L}^2(\Gamma)} + \|\nabla \bar{u}\|_{\mathcal{L}^2(\Gamma)}^2 \\
+ \left( \mathcal{F}, -\Delta(\omega \bar{u}_t + \bar{u}) \right)_{\mathcal{L}^2(\Omega)} + \left( \mathcal{G}, \bar{u}_t + \bar{u} + \bar{u} \right)_{\mathcal{L}^2(\Gamma)} \\
= (1 - \omega)\|\nabla \bar{u}_t\|_{\mathcal{L}^2(\Omega)}^2 + (1 - \alpha \omega)\|\nabla \bar{u}\|_{\mathcal{L}^2(\Gamma)}^2.
\]

We estimate the following products with Young’s inequality and the fact \( \mathcal{F} \) and \( \mathcal{G} \) are Lipschitz continuous on \( \mathcal{B}_0 \), and with (3.76)

\[
\omega(\nabla \bar{u}_t, \nabla \bar{u})_{\mathcal{L}^2(\Omega)} \geq -\omega\|\nabla \bar{u}_t\|_{\mathcal{L}^2(\Omega)}^2 - \frac{1}{4}\|\nabla \bar{u}\|_{\mathcal{L}^2(\Omega)}^2,
\]

\[
\alpha \omega(\nabla \bar{u}_t, \nabla \bar{u})_{\mathcal{L}^2(\Gamma)} \geq -\alpha \omega\|\nabla \bar{u}_t\|_{\mathcal{L}^2(\Gamma)}^2 - \frac{1}{4}\|\nabla \bar{u}\|_{\mathcal{L}^2(\Gamma)}^2,
\]

\[
\left( \mathcal{F}, -\Delta(\omega \bar{u}_t + \bar{u}) \right)_{\mathcal{L}^2(\Omega)} \geq -\frac{1}{4}\|\mathcal{F}\|_{\mathcal{L}^2(\Omega)}^2 - \|\Delta(\omega \bar{u}_t + \bar{u})\|_{\mathcal{L}^2(\Omega)}^2 \\
\geq -C\|\bar{u}_t\|^2_{\mathcal{H}_t}, e^{\mathcal{C} t} - \|\Delta(\omega \bar{u}_t + \bar{u})\|_{\mathcal{L}^2(\Omega)}^2,
\]

and

\[
\left( \mathcal{G}, \bar{u}_t + \bar{u} + \bar{u} \right)_{\mathcal{L}^2(\Gamma)} \geq -\frac{1}{4}\|\mathcal{G}\|^2_{\mathcal{L}^2(\Gamma)} - \|\bar{u}_t + \bar{u} + \bar{u}\|_{\mathcal{L}^2(\Gamma)}^2 \\
\geq -C\|\bar{u}_t\|^2_{\mathcal{H}_t}, e^{\mathcal{C} t} - \|\bar{u}_t + \bar{u} + \bar{u}\|_{\mathcal{L}^2(\Gamma)}^2.
\]

Combining (3.86)–(3.90), integrating the result over \((\delta, t)\) for any \( 0 < \delta < t \), and making some basic estimates on the remaining products gives us the estimate
where the constant \( C_\omega > 0 \) depends on \( \omega \) like \( \omega \sim \omega^{-1} \). Applying (3.77) to (3.91) shows that (3.85) holds for all \( t \geq \delta \), for any \( \delta > 0 \). Finally, inserting (3.85) into (3.84) establishes
\[
\| \tilde{a}_i(t) \|_{H^1(\Gamma)}^2 + \| \tilde{a}_i(t) \|_{H^1(\Gamma)}^2 \leq C_\omega \| \zeta_0 \|_{H^1}^2 e^{C_\zeta t},
\] (3.92)
Together, (3.92) and (3.76) yield the bound (3.61) as claimed. This concludes the proof. \( \square \)

Moving forward, we now show (H2) by making the appropriate 'lower-order' estimates in the norm of \( H_{-1} \).

**Lemma 3.26.** For all \( \alpha \in [0,1] \), condition (H2) holds.

**Proof.** Let \( \alpha \in [0,1] \), and \( \zeta_{01} = (u_{01}, u_{11}, \gamma_{01}, \gamma_{11}), \zeta_{02} = (u_{02}, u_{12}, \gamma_{02}, \gamma_{12}) \in B_0 \). For \( t > 0 \), let
\[
\zeta_1(t) = (u_1(t), u'_1(t), u''_1(t), u'''_1(t)) \quad \text{and} \quad \zeta_2(t) = (u_2(t), u'_2(t), u''_2(t), u'''_2(t)),
\]
denote the corresponding global solutions of problem \( P_\alpha \) on \([0,T]\) with the initial data \( \zeta_{01} \) and \( \zeta_{02} \), respectively. For all \( t \in (0,T) \), set
\[
\tilde{\zeta}(t) := \zeta_1(t) - \zeta_2(t) = (u_1(t), u'_1(t), u''_1(t), u'''_1(t)) - (u_2(t), u'_2(t), u''_2(t), u'''_2(t)) =: (\tilde{a}_i(t), \tilde{a}_i(t), \tilde{a}_i(t), \tilde{a}_i(t)),
\]
and
\[
\tilde{\zeta}_0 := \zeta_{01} - \zeta_{02} = (u_{01}, u_{11}, \gamma_{01}, \gamma_{11}) - (u_{02}, u_{12}, \gamma_{02}, \gamma_{12}) = (u_{01} - u_{02}, u_{11} - u_{12}, \gamma_{01} - \gamma_{02}, \gamma_{11} - \gamma_{12}) =: (a_0, a_1, \gamma_0, \gamma_1).
\]
For each \( t \geq 0 \), decompose the difference \( \tilde{\zeta}(t) := \zeta_1(t) - \zeta_2(t) \) with \( \tilde{\zeta}_0 := \zeta_{01} - \zeta_{02} \) as follows:
\[
\tilde{\zeta}(t) = (\tilde{\varphi}(t), \tilde{\varphi}_x(t), \tilde{\varphi}_{xx}(t), \tilde{\varphi}_{xxx}(t)) = (\tilde{\psi}(t), \tilde{\psi}_x(t), \tilde{\psi}_{xx}(t), \tilde{\psi}_{xxx}(t), \tilde{\psi}_{xxxx}(t), \tilde{\psi}_{xxxxx}(t)),
\]
where \( \tilde{\varphi}(t) \) and \( \tilde{\vartheta}(t) \) are solutions of the problems:
\[
\begin{cases}
\omega_\tau - \omega_\Delta \tilde{\varphi} + \tilde{\vartheta} - \Delta \tilde{\varphi} + \tilde{\vartheta} = 0 & \text{in } (0,\infty) \times \Omega \\
\omega_\tau + \partial_\nu (\tilde{\varphi} + \omega \tilde{\psi}) - \alpha_\omega \Delta_\Gamma \tilde{\varphi} + \tilde{\vartheta} - \Delta_\Gamma \tilde{\varphi} + \tilde{\vartheta} = 0 & \text{on } (0,\infty) \times \Gamma \\
\tilde{\varphi}(0) = \zeta_0 & \text{at } [0] \times \Omega,
\end{cases}
\] (3.93)
\[ \begin{align*}
\phi_t - \omega \Delta \phi_t + \phi_t - \Delta \phi + \dot{\phi} &= f(u^2) - f(u') & \text{in} \quad (0, \infty) \times \Omega \\
\phi_t + \partial_\alpha (\bar{w} + \omega \phi_t) - \alpha \omega \Delta \Gamma \phi_t + \phi_t - \Delta \Gamma \phi + \phi_t &= g(u^2) - g(u') & \text{on} \quad (0, \infty) \times \Gamma \\
\bar{\phi}(0) &= 0 & \text{at} \quad \{0\} \times \Omega.
\end{align*} \] (3.94)

Let \( \varepsilon \in (0, 1) \) be chosen later and let
\[ \tilde{\phi}(t) := \int_0^t e^{-\varepsilon(t-\tau)} \psi(\tau) d\tau, \]
for some \( \varepsilon \in (0, 1) \) to be determined later below. Observe, \( \tilde{\phi}_t + \varepsilon \tilde{\phi} = \tilde{\psi} \) and \( \tilde{\phi}(0) = 0 \). Multiply equations (3.93)\(_1\)–(3.93)\(_2\) by \( \varepsilon(t-\tau) \) and integrate with respect to \( \tau \) over \( (0, t) \) to find,
\[ \tilde{\phi}_t(t) - \omega \Delta \tilde{\phi}(t) + \tilde{\phi}(t) - \Delta \tilde{\phi}(t) + \tilde{\phi}(t) = 0 \quad \text{in} \quad \Omega, \] (3.95)
and
\[ \tilde{\phi}_t(t) + \partial_\alpha (\bar{w} \tilde{\phi}(t) + \tilde{\phi}(t)) - \alpha \omega \Delta \Gamma \tilde{\phi}(t) + \tilde{\phi}(t) - \Delta \Gamma \tilde{\phi}(t) + \tilde{\phi}(t) = 0 \quad \text{on} \quad \Gamma. \] (3.96)

Hence, here we obtain the differential identity,
\[ \frac{d}{dt} \left( 2 \varepsilon \langle \bar{\phi}_t, \tilde{\phi} \rangle_{L^2(\Omega)} + \| \tilde{\phi} \|_{H^1(\Omega)}^2 \right) + 2 \varepsilon \langle \bar{\phi}_t, \tilde{\phi} \rangle_{L^2(\Gamma)} + \| \tilde{\phi} \|_{H^1(\Gamma)}^2 \right) \]
\[ + 2 \varepsilon \langle \bar{\phi}_t, \tilde{\phi} \rangle_{L^2(\Omega)} + 2 \varepsilon \langle \bar{\phi}_t, \tilde{\phi} \rangle_{L^2(\Gamma)} + \| \tilde{\phi} \|_{H^1(\Gamma)}^2 \right) \]
\[ + 2 \varepsilon (\partial_\alpha (\bar{w} \tilde{\phi}(t) + \tilde{\phi}(t)) - \alpha \omega \Delta \Gamma \tilde{\phi}(t) + \tilde{\phi}(t) - \Delta \Gamma \tilde{\phi}(t) + \tilde{\phi}(t) = 0. \] (3.97)

As in the proof of proposition 3.25, multiplication of (3.63)–(3.64) in \( L^2(\Omega) \) by \( \bar{\theta}_t + \varepsilon \bar{\theta} \) is defined.

Now we define the functional, for all \( \zeta = (u, v, \gamma, \delta) \in H^1_0 \) and for each \( \varepsilon > 0 \),
\[ \Phi(\zeta) := \| \zeta \|_{H^1_0}^2 + 2 \varepsilon \langle u, v \rangle_{L^2(\Omega)} + 2 \varepsilon \langle \gamma, \delta \rangle_{L^2(\Gamma)}. \] (3.98)

Observe, with the Cauchy–Schwarz inequality, Sobolev (1.12), and the trace embedding \( H^1(\Omega) \hookrightarrow L^2(\Gamma) \), a straightforward calculation shows there are constants \( C_1, C_2 > 0 \), such that, for all \( t \geq 0 \),
\[ C_1 \| \zeta \|_{H^1_0}^2 \leq \Phi(\zeta) \leq C_2 \| \zeta \|_{H^1_0}^2. \] (3.99)

We will denote \( \Phi(\cdot) \) along trajectories \( \bar{\phi}(t) := (\bar{\phi}(t), \delta(t), \bar{\phi}_{\Gamma}(t), \delta_{\Gamma}(t)), t > 0, \) by \( \Phi(t) \); also, the map \( t \mapsto \Phi(t) \) is \( C^1((0, \infty)) \). With (3.98) and the basic estimates
\[2\varepsilon \omega \langle \nabla \chi_t, \nabla \chi \rangle_{L^2(\Gamma)} \geq -2\omega \varepsilon \cdot \frac{1}{\varepsilon} \| \nabla \chi_t \|^2_{L^2(\Gamma)} - 2\omega \varepsilon \cdot \frac{\varepsilon}{4} \| \nabla \chi \|^2_{L^2(\Gamma)},\]

\[\geq -2\omega \| \nabla \chi_t \|^2_{L^2(\Gamma)} - \frac{\omega \varepsilon^2}{2} \| \chi \|^2_{H^1(\Omega)}, \tag{3.100}\]

and

\[2\varepsilon \alpha \omega \langle \nabla \chi_t, \nabla \chi \rangle_{L^2(\Gamma)} \geq -2\alpha \omega \varepsilon \cdot \frac{1}{\varepsilon} \| \nabla \chi_t \|^2_{L^2(\Gamma)} - 2\omega \varepsilon \cdot \frac{\varepsilon}{4} \| \nabla \chi \|^2_{L^2(\Gamma)},\]

\[\geq -2\omega \| \nabla \chi_t \|^2_{L^2(\Gamma)} - \frac{\omega \varepsilon^2}{2} \| \chi \|^2_{H^1(\Omega)}, \tag{3.101}\]

the identity (3.97) may be written into the following differential inequality,

\[
\frac{d}{dt} \Phi + 2(1 - \varepsilon) \| \Phi \|^2_{L^2(\Gamma)} + 2\varepsilon \langle \Phi, \tilde{\Phi} \rangle_{L^2(\Gamma)} + 2\varepsilon \left(1 - \frac{\omega \varepsilon}{4}\right) \| \tilde{\Phi} \|^2_{H^1(\Omega)}
\]

\[+ 2(1 - \varepsilon) \| \Phi \|^2_{H^1(\Gamma)} + 2\varepsilon \langle \Phi, \tilde{\Phi} \rangle_{L^2(\Gamma)} + 2\varepsilon \left(1 - \frac{\omega \varepsilon}{4}\right) \| \tilde{\Phi} \|^2_{H^1(\Gamma)}
\]

\[\leq 0. \tag{3.102}\]

Hence, for any \( \omega \in (0, 1) \), there is some \( \varepsilon \in (0, 1) \) and a \( \nu_2 > 0 \) in which (3.102) becomes, for almost all \( t \geq 0 \),

\[
\frac{d}{dt} \Phi + \nu_2 \Phi \leq 0. \tag{3.103}\]

Integration of (3.103) over \( (s, t) \) yields, with the aid of (3.99),

\[
\| \tilde{\varphi}(t) \|_{H^1} \leq C e^{-\nu_2 |t-s|/2} \| \tilde{\varphi}(s) \|_{H^1}, \tag{3.104}\]

where

\[
\tilde{\varphi}(t) = (\tilde{\varphi}(t), \tilde{\varphi}_I(t), \tilde{\varphi}_H(t), \tilde{\varphi}_I(t)).
\]

Since

\[
\| \tilde{\varphi}(t) \|_{H^1} = \left| \int_0^t e^{-\nu_2 |\tau-t|} \| \varphi(\tau) \|_{H^1} d\tau \right|
\]

\[= \| \tilde{\varphi}(t) \|_{H^1}, \tag{3.105}\]

(3.104) becomes, in the limit \( s \to 0^+ \),

\[
\| \tilde{\varphi}(t) \|_{H^1} \leq C e^{-\nu_2 t/2} \| \tilde{\zeta}_0 \|_{H^1}.
\]

Thus, (3.58) holds for with \( \kappa = C e^{-\nu_2 t/2} \) for any fixed \( t^* > \max \{ t_0, \frac{2}{\nu_2} \ln(2C) \} \).

It remains to show that (3.59) holds to complete the proof. Here we assume that

\[t^* > \max \left\{ t_0, \frac{2}{\nu_2} \ln(2C), \frac{t_0}{\nu_2} \right\} > 0,\]

1206
where \( \bar{t} > 0 \) is given by proposition 3.25. Let us now recall the proof of proposition 3.11. With the system in (3.94) and the appropriate multiplication by \( \bar{w}_0 \) in \( L^2(\Omega) \) and \( L^2(\Gamma) \), we arrive at, in place of (3.23), the estimate
\[
\frac{d}{dt} \| \bar{\vartheta} \|^2_{H_0} + 2\omega \| \bar{\vartheta} \|^2_{H^1(\Omega)} + 2\alpha \omega \| \bar{\vartheta} \|^2_{H^1(\Gamma)} \leq 2(f(u^1) - f(u^2), \bar{w}_1)_{L^2(\Omega)} - 2(g(u^1) - g(u^2), \bar{w}_1)_{L^2(\Gamma)}.
\] (3.106)

This time we estimate the products using (3.61) as follows, for any \( \varepsilon > 0 \), and for each \( t \in [0, t^*] \), where \( t^* > 0 \) was determined above,
\[
-2(f(u^1) - f(u^2), \bar{w}_1)_{L^2(\Omega)} \leq 2\| f(u^1) - f(u^2) \|_{L^2(\Omega)} \leq C\| u \|_{L^2(\Omega)}(1 + \| u^2 \|^2_{L^2(\Omega)} + \| u^2 \|^2_{H^1(\Omega)})\| \bar{w}_1 \|_{L^2(\Omega)} \leq C\| \bar{u} \|_{H^1(\Omega)}\| \bar{w}_1 \|_{H^1(\Omega)} \leq \varepsilon C(\| \bar{\vartheta}_0 \|_{H^{1, \varepsilon}}) e^{\varepsilon t} + \frac{1}{4\varepsilon} \| \bar{w}_1 \|^2_{H^1(\Omega)} \leq \varepsilon C(\| \bar{\vartheta}_0 \|_{H^{1, \varepsilon}}) e^{\varepsilon t} + \frac{1}{4\varepsilon} \| \bar{w}_1 \|^2_{H^1(\Omega)},
\] (3.107)

and similarly,
\[
-2(g(u^1) - g(u^2), \bar{w}_1)_{L^2(\Gamma)} \leq \varepsilon C(\| \bar{\vartheta}_0 \|_{H^{1, \varepsilon}}) e^{\varepsilon t^*} + \frac{1}{4\varepsilon} \| \bar{w}_1 \|^2_{H^1(\Gamma)} \].
\] (3.108)

Now together (3.106)–(3.108) produce,
\[
\frac{d}{dt} \| \bar{\vartheta} \|^2_{H_0} + \left( 2\omega - \frac{1}{4\varepsilon} \right) \| \bar{w}_1 \|^2_{H^1(\Omega)} + \left( 2\alpha \omega - \frac{1}{4\varepsilon} \right) \| \bar{w}_1 \|^2_{H^1(\Gamma)} \leq \varepsilon C(\| \bar{\vartheta}_0 \|_{H^{1, \varepsilon}}) e^{\varepsilon t} + \frac{1}{4\varepsilon} \| \bar{w}_1 \|^2_{H^1(\Omega)} \] (3.109)

Hence, for each \( \alpha \in [0, 1] \) and \( \omega \in (0, 1] \), we can find \( \varepsilon > 0 \) so that, upon integrating (3.109) over \( (0, t^*) \), there holds
\[
\| \bar{\vartheta}(t^*) \|^2_{H_0} \leq C(\| \bar{\vartheta}_0 \|_{H^{1, \varepsilon}}) t^* \] (3.110)

Note that we applied the initial conditions given in (3.94), and also, we may omit the (positive) integral of \( \| \bar{w}_1 \|^2_{H^1(\Omega)} \) and \( \| \bar{w}_1 \|^2_{H^1(\Gamma)} \) on the left-hand side of (3.109) in light of making an estimate similar to (3.21) for \( \bar{d} \). The final estimate (3.110) establishes (3.59) and finishes the proof.

**Lemma 3.27.** For all \( \alpha \in [0, 1] \), condition (H3) holds.

**Proof.** Let \( \alpha \in [0, 1] \), \( \bar{\zeta}_0, \bar{\zeta}_0 \in B_{2\delta_0} \) and \( t_0, t_2 \in [t^*, 2t^*] \). In the norm of \( H^{1, \varepsilon} \), we calculate
\[
\| S_\alpha(t_0) \bar{\zeta}_0 - S_\alpha(t) \bar{\zeta}_0 \|_{H^{1, \varepsilon}} \leq \| S_\alpha(t_0) \bar{\zeta}_0 - S_\alpha(t_0) \bar{\zeta}_0 \|_{H^{1, \varepsilon}} + \| S_\alpha(t) \bar{\zeta}_0 - S_\alpha(t_2) \bar{\zeta}_0 \|_{H^{1, \varepsilon}}.
\] (3.111)

The first term on the right-hand side of (3.111) is bounded, uniformly in \( t \) on compact intervals, by (3.61). We will deal with the remaining term only in the Gevrey case when \( \alpha = 0 \).
since the argument for the analytic case $\alpha \in (0, 1]$ is similar. For this, recall (3.3) from theorem 3.1: in the norm of $\mathcal{H}_0$, there is a constant $C > 0$ such that there holds, for all $t > 0$,

$$
\|\partial_t \zeta(t)\|_{\mathcal{H}_0} \leq \frac{d}{dt} \left\| e^{At} \zeta \right\|_{\mathcal{H}_0} + \| F(\zeta(t)) \|_{\mathcal{H}_0} \leq \frac{C}{t^2} \| \zeta_0 \|_{\mathcal{H}_0} + \| F(\zeta(t)) \|_{\mathcal{H}_0}.
$$

(3.112)

Because $t_1, t_2 \in [t^*, 2t^*]$ and $\zeta_0 \in \mathcal{B}_0$, we can use (2.3), (2.4) and the continuous embedding $\mathcal{H}_0 \hookrightarrow \mathcal{H}_{-1}$ to easily show that the second term on the right-hand side of (3.111) is globally bounded in $\mathcal{H}_{-1}$, whereby, the desired Lipschitz continuity property (3.60) naturally follows for the analytic case, $\alpha \in (0, 1]$. This concludes the proof.

**Remark 3.28.** Concerning the proof of lemma 3.27, when $\alpha > 0$ a simpler proof follows directly from the theory of analytic semigroups. Indeed, since the operator $A_\alpha$ is analytic and the map $t \mapsto F(\zeta(t))$ is $C([0, \infty); \mathcal{H}_0)$, we may apply standard results from [37, 38], for example. Then, for any $\delta > 0$,

$$
\partial_t \zeta(t) = (u_t(t), u_\alpha(t), u_{\alpha(t)}, u_{\alpha(t)\|L}) \in C([\delta, \infty); \mathcal{H}_0).
$$

Now with $t_1, t_2 \in [t^*, 2t^*]$ and $\zeta_0 \in \mathcal{B}_0$, a simple estimate using (3.15) shows $\partial_t \zeta(t)$ is uniformly bounded in $\mathcal{H}_0$ and the result now follows.

**Remark 3.29.** According to proposition 3.24, the semiflow $S_\alpha(t) : \mathcal{H}_0 \to \mathcal{H}_0$ possesses an exponential attractor $\mathcal{M}_{-1,\alpha} \subset \mathcal{B}_0$, which attracts bounded subsets of $\mathcal{B}_0$ exponentially in the topology of $\mathcal{H}_{-1}$. Thus, the global attractors $\mathcal{A}_\alpha$ are finite dimensional in the topology of $\mathcal{H}_{-1}$. In order to show that the attraction property in theorem 3.21 part (3) also holds, we appeal to the transitivity of the exponential attraction described in the proceeding proposition.

The next result is the so-called transitivity property of exponential attraction from [17, theorem 5.1].

**Proposition 3.30.** Let $(\mathcal{X}, d)$ be a metric space and let $S_t$ be a semigroup acting on this space such that

$$
d(S_t m_1, S_t m_2) \leq C e^{K d(m_1, m_2)},
$$

for appropriate constants $C$ and $K$. Assume that there exists three subsets $U_1, U_2, U_3 \subset \mathcal{X}$ such that

$$
\text{dist}_\mathcal{X}(S_t U_1, U_2) \leq C_1 e^{-\alpha t} \quad \text{and} \quad \text{dist}_\mathcal{X}(S_t U_2, U_3) \leq C_2 e^{-\alpha t}.
$$

Then

$$
\text{dist}_\mathcal{X}(S_t U_1, U_3) \leq C e^{-\alpha' t},
$$

where $C' = C_{1} + C_{2}$ and $\alpha' = \frac{\alpha_{01} \alpha_{02}}{K + \alpha_1 + \alpha_2}$.

The following corollary provides an interesting endnote to theorem 3.21.

**Corollary 3.31 (Corollary to theorem 3.21).** Let $\mathcal{M}_{-1,\alpha}$ be the weak exponential attractor admitted by the semiflow $S_\alpha$, $\alpha \in [0, 1]$. Then for each $\alpha \in [0, 1]$, the set

$$
\widehat{\mathcal{M}}_{\alpha} := \bigcup_{t > 0} S_\alpha(t) \mathcal{M}_{-1,\alpha}.
$$
is positively invariant in $\mathcal{H}_0$. The set $\tilde{\mathcal{M}}_0$ is bounded in $D(A_0^{1/2})$, and when $\alpha \in (0, 1]$, $\tilde{\mathcal{M}}_0$ is bounded in $D(A_0)$.

**Proof.** The asserted bounds follow directly from (3.16). The proof of the positive invariance is a straightforward calculation relying on the semigroup properties of $S_\alpha$; indeed, for all $\alpha \in [0, 1]$,

$$
S_\alpha(t)\tilde{\mathcal{M}}_0 = S_\alpha(t)\Bigg( \bigcup_{s>0} S_\alpha(s)\mathcal{M}_{-1,\alpha} \Bigg) = \bigcup_{s>0} S_\alpha(t+s)\mathcal{M}_{-1,\alpha} \\
\subseteq \bigcup_{\tau>0} S_\alpha(\tau)\mathcal{M}_{-1,\alpha} = \bigcup_{\tau>0} S_\alpha(\tau)\mathcal{M}_{-1,\alpha} = \tilde{\mathcal{M}}_0.
$$

(3.113)

This completes the proof.

**Remark 3.32.** Notice that we are not claiming that the sets $\tilde{\mathcal{M}}_\alpha$ are compact, finite dimensional, nor (exponential) attractors.

### 4. Conclusions

In this article, we showed that the strongly damped perturbation of the weakly damped semilinear wave equation with hyperbolic dynamic boundary conditions possesses a semiflow generated by the mild solutions, in two different cases, the first corresponding to an abstract problem where the associated operator generates a $C_0$-semigroup of Gevrey class $\delta$ for $\delta > 2$, with the other case corresponding to an analytic semigroup. Each case assumes the interior (bulk) potential has subcritical nonlinearity. After proving the existence of an absorbing set, we showed the associated semiflows admit a global attractor in the standard energy phase space. Indeed, we obtain the required asymptotic compactness through a suitable ‘$\alpha$-contraction’ argument, which turns out to be rather necessary since other means known to evolution equations with dynamic boundary conditions cannot be applied here. With that, we were able to establish certain decay and compactness properties over the decomposition of the difference of two solutions, at least in the weak topology. The uniform global Lipschitz continuity of the semiflow on the absorbing set yielded the existence of weak exponential attractors, bounded in the standard topology, and compact in the weak topology. The finite fractal dimension of the weak exponential attractors insures that the global attractors also possess finite fractal dimension, at least in the weak topology. We also establish the upper-semicontinuity result for the family of global attractors $\mathcal{A}_\alpha$, as $\alpha \to 0$, in the standard phase space $\mathcal{H}_0$.

It would be interesting (if possible) to extend the results presented here to the case of critical nonlinearities; e.g. replace the growth condition (1.10) with the following,

$$
|f(r) - f(s)| \leq C|r - s|(1 + |r|^4 + |s|^4).
$$

What keeps us from that presentation here is the lack of the local Lipschitz property for the nonlinear functional $F$. Recall, the mild solutions obtained here come through semigroup theory, and they are not necessarily the same as weak solutions (see remark 2.5). Since weak solutions would not necessarily require that $F$ be locally Lipschitz on the weak energy phase space, one could feasibly employ an arbitrary (polynomial) growth condition, probably at the cost of introducing a new term, e.g. $||u||_p^p$ instead of the norm of the standard energy phase space. On the other hand, the difficulty with weak solution in this setting arises when attempting to obtain precompactness of the semiflow. Here, fractional powers of the Laplacian on $\Omega$ are not defined. Moreover, because of the dynamic flux component of the boundary condition,
i.e. $\omega \partial_t u$, there is no suitable $H^2$-regularity estimate that can be used to bound (part of) the solution operator in some smoother space. Even for the strongly damped wave associated with homogeneous Dirichlet boundary conditions, when the power of the leading Dirichlet–Laplace operator equaled one, i.e. $\omega (-\Delta)^{\theta}, \theta = 1$, the weak solutions obtained in [6, 7] followed after a nontrivial application of a nonlinear Alekseev’s variation of constants formula.

Theorem 3.1 says something slightly more general than what we used here to prove that the semiflow was well-posed. As previously mentioned, the nonlinearity represented by the functional $F$ is locally Lipschitz on the energy space $H_0$. More generally, it need only be locally Lipschitz as a map from $D(A_0^\theta) \rightarrow H_0$ for $\theta \in [0, \frac{1}{2})$, where $\gamma = 1$ if $\alpha > 0$ and $\gamma = 2$ if $\alpha = 0$. For this reason, it would be interesting to achieve a full characterization of the domains of fractional powers of $A_\alpha$, see Chen and Triggiani’s result [10]. Indeed, we may offer up the following conjecture.

**Conjecture 4.1.** For $\alpha \in (0, 1]$, we have

$$D(A_\alpha^\theta) \subset H^0(\Omega) \times H^{\min\{1,2\theta\}}(\Omega) \times H^1(\Gamma) \times H^{\min\{1,2\theta\}}(\Gamma)$$

for all $0 \leq \theta \leq 1$.

For $\alpha = 0$, we have

$$D(A_\alpha^\theta) \subset H^0(\Omega) \times H^{\min\{1,2\theta\}}(\Omega) \times H^1(\Gamma) \times H^{\min\{1,2\theta\}}(\Gamma)$$

for all $0 \leq \theta \leq 1$.

The first statement of this conjecture may be obtained by analogy with [10, theorem 1.1]. In fact, one can show in the case where $\alpha = 1$ that $A_\alpha$ matches exactly the form of the operator appearing in [10] (see also [9]) and therefore not only does the conjecture above hold, but the opposite containment also holds (so that the two sets are equal). The other cases are considerably more complicated. The statement for $\alpha = 0$ may be defended by analogy with the domain $D(A_\alpha)$, in which the fourth component is in $H^{1/2}(\Gamma)$, a loss of ‘one-half derivative’ as compared to the domain $D(A_\alpha)$ for $\alpha > 0$. A proof of this conjecture, though interesting, would not, however, allow us to generalize growth condition (1.8), because the first component in the domain of the generator (and its fractional powers) is still only $H^1$. Thus, if one is seeking to prove the well-posedness of the semiflow using theorem 3.1, then the results given in this paper are optimal.

Another interesting direction for some future work could involve investigating the well-posedness, regularity, and asymptotic behavior corresponding to the case when $\omega = 0$. In addition to bounding the (fractal) dimension of the attractors in $H_0$, at least in the case $\omega = 0$, after further work, the continuity properties of the associated attractors may be sought; for example, the upper-semicontinuity of the global attractors at $\omega = 0$ and the existence of a robust (Hölder continuous) family of exponential attractors for $\omega \in [0, 1]$. Based on section 3.4 and the work [18, section 4], the upper-semicontinuity result may follow by assuming only $f, g \in C(\mathbb{R})$ satisfy (1.8)–(1.11). However, with additional regularity properties from the global attractors, the more traditional arguments used to show upper-semicontinuity of global attractors in [28, 29] (also see [32, theorem 3.31]) may also prove successful. On the other hand, one may inquire about applying a perturbation parameter $\epsilon$ to the inertial terms $u_{\alpha t}$, then letting this approach zero. Then, this of course is just a special case arising from a so-called memory relaxation of the Allen–Cahn equation equipped with dynamic boundary conditions.
