EDGE OF SPIKED BETA ENSEMBLES, STOCHASTIC AIRY SEMIGROUPS AND REFLECTED BROWNIAN MOTIONS

PIERRE YVES GAUDREAU LAMARRE AND MYKHAYLO SHKOLNIKOV

ABSTRACT. We access the edge of Gaussian beta ensembles with one spike by analyzing high powers of the associated tridiagonal matrix models. In the classical cases $\beta = 1, 2, 4$, this corresponds to studying the fluctuations of the largest eigenvalues of additive rank one perturbations of the GOE/GUE/GSE random matrices. In the infinite-dimensional limit, we arrive at a one-parameter family of random Feynman-Kac type semigroups, which features the stochastic Airy semigroup of Gorin and Shkolnikov [13] as an extreme case. Our analysis also provides Feynman-Kac formulas for the spiked stochastic Airy operators, introduced by Bloemendal and Virág [6]. The Feynman-Kac formulas involve functionals of a reflected Brownian motion and its local times, thus, allowing to study the limiting operators by tools of stochastic analysis. We derive a first result in this direction by obtaining a new distributional identity for a reflected Brownian bridge conditioned on its local time at zero.

1. Introduction

A remarkable advance in the study of random matrices and related point processes has been the development of a theory of operator limits for such objects in [6], [7], [11], [13], [15], [17], [25], [26], [27], [29], [30]. This line of research originates from the publications [10], [11] by Edelman and Sutton, who have realized that the random tridiagonal matrices of Dumitriu and Edelman [9] (see (1.2) below for a definition) can be viewed as finite-dimensional approximations of suitable random Schrödinger operators. Since the joint eigenvalue distributions in the Dumitriu-Edelman models for the parameter values $\beta = 1, 2, 4$ are given by the eigenvalue point processes of the Gaussian orthogonal/unitary/symplectic ensembles (GOE/GUE/GSE), respectively, the insights of [10], [11] suggest that the limiting fluctuations of the largest eigenvalues of the latter can be read off from the random Schrödinger operators associated with the former. This approach has been carried out rigorously in the seminal paper [26] by Ramírez, Rider and Virág. We also refer to [17] for a corresponding universality result, to [6], [7] for extensions to spiked random matrix ensembles, to [25], [15], [27] for operator limits describing the fluctuations of the smallest eigenvalues of large positive definite random matrices.

2010 Mathematics Subject Classification. 60B20, 60H25, 47D08, 60J55.

Key words and phrases. Beta ensembles, Feynman-Kac formulas, local times, low rank perturbations, moments method, operator limits, path transformations, random tridiagonal matrices, reflected Brownian motions, Skorokhod map, stochastic Airy semigroups, strong invariance principles.

P. Y. Gaudreau Lamarre is partially supported by an NSERC Doctoral Fellowship and a Gordon Y. S. Wu Fellowship. M. Shkolnikov is partially supported by the NSF grant DMS-1506290.
and to [29], [30] for operators arising in the study of the bulk eigenvalues of random matrices.

More recently, Gorin and Shkolnikov [13] have proposed a different operator limit approach to the study of the largest eigenvalues in the Gaussian beta ensembles. The latter are point processes on the real line, in which the joint density of the points $\lambda_1 \geq \lambda_2 \geq \cdots \geq \lambda_N$ is proportional to

$$\prod_{1 \leq q_1 < q_2 \leq N} (x_{q_1} - x_{q_2})^\beta \prod_{q=1}^N e^{-\beta x_q^2/4}. \quad (1.1)$$

For $\beta = 1, 2, 4$, the Gaussian beta ensemble describes the eigenvalue process of a random matrix from the GOE/GUE/GSE, respectively (see e.g. [1, Section 2.5]).

Gaussian beta ensembles with general values of $\beta > 0$ appear frequently in the statistical physics literature and are commonly known therein as “log-gases”, see e.g. [12, Section 4.1].

The starting point of [13] is the celebrated result of Dumitriu and Edelman [9] establishing (1.1) as the joint eigenvalue distribution, for all values of $\beta > 0$, of the random matrix

$$H_N^\beta := \frac{1}{\sqrt{\beta}} \begin{bmatrix} \sqrt{2}G_1 & \chi_{(N-1)\beta} & \chi_{(N-2)\beta} \\ \chi_{(N-1)\beta} & \sqrt{2}G_2 & \chi_{(N-2)\beta} \\ \chi_{(N-2)\beta} & \sqrt{2}G_3 & \ddots \\ \ddots & \ddots & \ddots \\ \chi_{\beta} & \sqrt{2}G_N & \chi_{\beta} \end{bmatrix}, \quad (1.2)$$

where $G_1, G_2, \ldots, G_N$ are independent standard Gaussian random variables, $\chi_\beta$, $\chi_{2\beta}$, $\cdots$, $\chi_{(N-1)\beta}$ are independent chi random variables indexed by their parameters, and the chi random variables are independent of the Gaussian random variables. Then, the convergence in finite-dimensional distribution sense, as $N \to \infty$, of the fluctuations

$$\Lambda_{q,N} := N^{1/6}(2\sqrt{N} - \lambda_q), \quad q = 1, 2, \ldots \quad (1.3)$$

to the eigenvalues $\Lambda_1 \leq \Lambda_2 \leq \cdots$ of the stochastic Airy operator

$$H^\beta f := -\frac{d^2}{dx^2} + x + \frac{2}{\sqrt{\beta}} W'_x f, \quad f \in L^2([0, \infty)), \quad f(0) = 0 \quad (1.4)$$

(see [26, Theorem 1.1]), where $W'$ is the white noise on $[0, \infty)$, and the simple computation

$$\left(\frac{\lambda_q}{2\sqrt{N}}\right)^{[TN^{2/3}]} \approx \left(1 - \frac{\Lambda_{q,N}}{2N^{2/3}}\right)^{[TN^{2/3}]} \to e^{-T\Lambda_q/2}, \quad T \geq 0 \quad (1.5)$$

suggest the convergence of the random matrices $\left(\frac{H_N^\beta}{\sqrt{N}}\right)^{[TN^{2/3}]}$, $N \in \mathbb{N}$ to $e^{-TH^\beta/2}$ in a suitable operator topology. The main result of [13] (see [13, Theorem 2.8]) establishes a more general version of such an operator convergence directly, without relying on the findings of [26]. In contrast to $H^\beta$, the operator $e^{-TH^\beta/2}$ is an integral operator, and the corresponding integral kernel can be written in terms of the Brownian motion $W$ and an independent Brownian bridge (see [13, equation
This allows to study the properties of $e^{-T H^\beta/2}$ by tools of stochastic analysis (see [13, Proposition 2.14], [14, Theorem 1.1] for an example).

In this paper, we continue the program initiated in [13] and consider the case of Gaussian beta ensembles with one spike. To this end, it is useful to recall that the stochastic Airy operator $H^\beta$ describes the limiting behavior of the largest eigenvalues in the Laguerre beta ensemble (see [26], [9]). The latter interpolates between the eigenvalue processes of sample covariance matrices $XX^*$, where the entries of $X$ are independent standard Gaussian random variables. From the point of view of statistical applications, the Laguerre beta ensemble is arguably not the most interesting model, since the entries in the columns of $X$ are uncorrelated. Instead, one often considers multiplicative perturbations of $XX^*$ of the form $X\Sigma X^*$, where $\Sigma = \tilde{\Sigma}_r \oplus I_{N-r}$ is the direct sum of a deterministic full rank $r \times r$ matrix $\tilde{\Sigma}_r$ and the $(N-r) \times (N-r)$ identity matrix $I_{N-r}$. Such models are known in the literature as the spiked covariance models, and we refer to the introduction in [6] for an excellent summary.

As first discovered by Baik, Ben Arous and Péché [2] in the case of complex covariance matrices, the fluctuations of the largest eigenvalues exhibit a phase transition (known as the BBP phase transition) depending on the size of the perturbation. In the subcritical regime, the perturbation $\Sigma$ is so insignificant that the limiting behavior is the same as in the unperturbed case; in the critical regime, the fluctuation exponents are the same as in the unperturbed case, but the limiting distributions are different; and in the supercritical regime, the size of the perturbation is so large that the largest eigenvalues of $XX^*$ separate from the bulk of the spectrum.

For rank one perturbations, the critical regime of the BBP phase transition has been analyzed in detail by Bloemendal and Virág [6], and we describe their main result in the case of an additive perturbation. The corresponding tridiagonal model

\begin{equation}
H_N^{\beta,w} := \frac{1}{\sqrt{\beta}} \begin{bmatrix}
\sqrt{2} \chi_1 \\
\sqrt{2} \chi_2 \\
\sqrt{2} \chi_3 \\
\ddots \\
\sqrt{2} \chi_N
\end{bmatrix}
\end{equation}

can be obtained for $\beta = 1, 2, 4$ by applying the Dumitriu-Edelman tridiagonalization procedure to the sum of a GOE/GUE/GSE matrix and a rank one matrix with non-zero eigenvalue $\sqrt{N}\ell_N$, where

\begin{equation}
\lim_{N \to \infty} N^{1/3} (1 - \ell_N) = w \in \mathbb{R}.
\end{equation}

Then, for all $\beta > 0$ and under the scaling of (1.3), the ordered eigenvalues of $H_N^{\beta,w}$ converge in finite-dimensional distribution sense, as $N \to \infty$, to the ordered eigenvalues of the spiked stochastic Airy operator

\begin{equation}
H^{\beta,w} f := \left( -\frac{d^2}{dx^2} + x + \frac{2}{\sqrt{\beta}} W'_x \right) f, \quad f \in L^2([0, \infty)), \quad f'(0) = w f(0).
\end{equation}

The case $w = \infty$ formally corresponds to the Dirichlet boundary condition $f(0) = 0$, motivating the convention $H^{\beta,\infty} := H^{\beta}$. 
Remark 1.1. The limit in (1.7) determines the regime in the BBP phase transition: a limit of $\infty$ corresponds to the subcritical regime, a finite limit to the critical regime, and a limit of $-\infty$ to the supercritical regime.

We turn to our main results. For the sake of convenience, we work with a modification of the tridiagonal model (1.6):

\begin{equation}
M_N^{\beta,w} := \begin{bmatrix}
\sqrt{N}\ell_N & \sqrt{N} + \xi_0 \\
\sqrt{N} + \xi_0 & a_1 & \sqrt{N} - 1 + \xi_1 \\
& \sqrt{N} - 1 + \xi_1 & a_2 & \ddots \\
& & \ddots & \ddots & 1 + \xi_{N-1} \\
& & & & 1 + \xi_N
\end{bmatrix}.
\end{equation}

The following assumption summarizes the conditions we impose on the matrix entries throughout the paper. We emphasize that we allow the random variables $a_1, a_2, \ldots$ and $\xi_0, \xi_1, \ldots$ to vary with $N$, even though the dependence on $N$ is suppressed to simplify the notation.

Assumption 1.2. The random variables $a_1, a_2, \ldots$ and $\xi_0, \xi_1, \ldots$ are mutually independent and such that:
(a) $|E[a_m]| = o((N-m)^{-1/3})$ and $|E[\xi_m]| = o((N-m)^{-1/3})$ as $(N-m) \to \infty$,
(b) $E[a_m] = s_n^2 + o(1)$ and $E[\xi_m] = s_\xi^2 + o(1)$ as $(N-m) \to \infty$, where $s_n, s_\xi$ are non-negative constants satisfying $s_n^2 + s_\xi^2 = \frac{1}{\beta}$ for some $\beta > 0$,
(c) $E[|a_m|^p] \leq C p^{\gamma p}$ and $E[|\xi_m|^p] \leq C p^{\gamma p}$ for all $N, m$ and $p$, with some constants $C < \infty$ and $0 < \gamma < 2/3$.

Moreover, we assume that the non-random sequence $\ell_N, N \in \mathbb{N}$ satisfies (1.7) and use the convention $a_0 := 0$.

Remark 1.3. Assumption 1.2 holds, in particular, when the $a_m$’s are chosen to be i.i.d. Gaussian with mean 0 and variance $2/\beta$, whereas the $\xi_m$’s are drawn independently such that each $\sqrt{\beta}(\sqrt{N-m} + \xi_m)$ is a chi random variable with parameter $\beta(N-m)$ (see [13, Lemma 2.2]).

Motivated by the computation in (1.5), we consider the powers

\begin{equation}
M_N^{\beta,w} := \left( \frac{M_N^{\beta,w}}{2\sqrt{N}} \right)^{[TN^{2/3}]}, \quad T \geq 0.
\end{equation}

The operator limits of the latter turn out to be given by the following definition.

Definition 1.4. For every $\beta, T > 0$ consider the operator

\begin{equation}
(\mathcal{U}_{T,w}^{\beta}) f)(x) := E_{R^+} \left[ \exp \left( - \int_0^T \frac{R_t^2}{2} \, dt + \int_0^\infty \frac{L_0^w(R^t)}{\sqrt{\beta}} \, dW_a - w L_0^0(R^t) \right) \right] f(R_T^t)
\end{equation}

acting on the space

\begin{equation}
\mathcal{D} := \left\{ f \in L^1_{\text{loc}}([0, \infty)) : \ |f(x)| \leq C_1 e^{C_2 x^{1-\delta}} \text{ for some } C_1, C_2 < \infty, \delta \in (0, 1) \right\},
\end{equation}

where
(a) $R^x$ is a reflected Brownian motion started at $x \geq 0$,
(b) $E_{R^x} [\cdot]$ is the expectation with respect to $R^x$,
(c) the local time of $R^x$ is defined as the continuous version of

$$L^a_T(R^x) := \lim_{\epsilon_1,\epsilon_2 \to 0} \frac{1}{\epsilon_1 \epsilon_2} \int_0^T 1_{[\epsilon_1,\epsilon_2]}(R^x_t) \, dt, \quad a \geq 0,$$

(d) $W$ is a standard Brownian motion independent of $R^x$,
(e) the Itô integral with respect to $W$ is defined pathwise, as per [10].

**Remark 1.5.** A trivial restatement of Definition [1.3] is that $U^\beta_{T,w}$ is a random integral operator with the kernel

$$K_T^{\beta;w}(x,y) := \frac{\exp \left( -\frac{(x-y)^2}{2T} \right) + \exp \left( -\frac{(x+y)^2}{2T} \right)}{\sqrt{2\pi T}} \cdot E_{R^x} \left[ \exp \left( -\int_0^T \frac{R^x_t}{2} \, dt + \int_0^\infty \frac{L^a_T(R^x)}{\sqrt{\beta}} \, dW_a - u^{-1} \int_0^T \frac{R^x_t}{2} \, dt \right) \middle| R^x_T = y \right].$$

**Remark 1.6.** For each $N$, the matrix $M^\beta_{T,N}$ can be regarded as an integral operator acting on $L^1_N([0,\infty))$ by associating $R^{N+1}$ with the subspace of step functions

$$L^1_N([0,\infty)) := \left\{ \sum_{i=0}^N v_i 1_{[N^{-1/3},N^{-1/2}]}(t+1) : v_0, v_1, \ldots, v_N \in \mathbb{R} \right\},$$

and then mapping functions $f \in L^1_N([0,\infty))$ into $L^1_N([0,\infty))$ via

$$\langle \pi_N f \rangle(x) := \sum_{i=0}^N N^{1/6} \int_{N^{-1/2}}^{N^{-1/3}+1} f(y) \, dy \cdot 1_{[N^{-1/3},N^{-1/2}]}(x)$$

before acting with $M^\beta_{T,N}$ on them.

Our main convergence result reads as follows.

**Theorem 1.7.** For every $\beta > 0$, $w \in \mathbb{R}$, and with $D$ defined in (1.12), one has

$$\forall f, g \in D, T \geq 0 : \lim_{N \to \infty} \langle \pi_N f \rangle^\top \pi_N g = \int_0^\infty f(x) (U^\beta_{T,w} g)(x) \, dx,$$

where the convergence is in distribution and in the sense of moments. Moreover, these convergences hold jointly for any finite collection of $T$’s, $f$’s and $g$’s, and in the case of the convergence in distribution also jointly with the convergence in distribution

$$\sqrt{\beta} \lim_{N \to \infty} N^{-1/6} \sum_{m=0}^{[N^{1/3} x]} \left( \frac{a_m}{2} + \xi_m \right) = W_x, \quad x \geq 0,$$

with respect to the Skorokhod topology. Here $W$ is the Brownian motion from (1.11).

Next, we present some natural properties of the operators $U^\beta_{T,w}, T \geq 0$, viewed as operators on $L^2([0,\infty))$, and, in particular, connect them to the spiked stochastic Airy operator $H^\beta_{\gamma,w}$ in (1.5).

**Proposition 1.8.** For every $\beta > 0$ and $w \in \mathbb{R}$, the following statements hold.
(a) If the same Brownian motion $W$ is used in the definitions of $H^{\beta,w}$ and $U^{\beta,w}_T$, then for every $T \geq 0$,

$$U^{\beta,w}_T = \exp\left(-\frac{T}{2} H^{\beta,w}\right)$$

almost surely, in the sense that if $(f_q, \Lambda_q : q \in \mathbb{N})$ are the eigenfunction-eigenvalue pairs of $H^{\beta,w}$, then $U^{\beta,w}_T$ is the unique operator on $L^2([0,\infty))$ with eigenfunction-eigenvalue pairs $(f_q, e^{-T\Lambda_q/2} : q \in \mathbb{N})$ almost surely.

(b) The family $(U^{\beta,w}_T : T \geq 0)$ has the almost sure semigroup property in the sense that for all $T_1, T_2 \geq 0$, one has $U^{\beta,w}_{T_1} U^{\beta,w}_{T_2} = U^{\beta,w}_{T_1 + T_2}$ almost surely.

(c) For every $T > 0$, the operator $U^{\beta,w}_T$ is symmetric, non-negative and belongs to the Hilbert-Schmidt class almost surely.

(d) For every $T > 0$, the operator $U^{\beta,w}_T$ is almost surely trace class and obeys the trace formula

$$\text{Tr}(U^{\beta,w}_T) = \int_0^\infty K^{\beta,w}_T(x,x) \, dx.$$

(e) The family $(U^{\beta,w}_T : T \geq 0)$ is $L^2$-strongly continuous in expectation, that is, for all $p > 0$, $T \geq 0$ and $f \in L^2([0,\infty))$, one has

$$\lim_{t \to T} \mathbb{E}\left[\left\|U^{\beta,w}_T f - U^{\beta,w}_t f\right\|_{L^2([0,\infty))}^p\right] = 0.$$

Remark 1.9. Proposition 1.8(a) should be viewed as a Feynman-Kac formula for the spiked stochastic Airy operator $H^{\beta,w}$.

Remark 1.5 shows that one might be able to understand observables of the limiting operators $U^{\beta,w}_T : T \geq 0$, such as moments of certain linear statistics of their spectra, by investigating the corresponding functionals of reflected Brownian motions conditioned on their endpoints. As a first step in this direction, we consider $\mathbb{E}[K^{\beta,w}_T(0,0)]$, which, in view of the next proposition, seems to be the simplest object to study.

Proposition 1.10. For every $\beta, T > 0$ and $w \in \mathbb{R}$,

$$\mathbb{E}[K^{\beta,w}_T(0,0)] = \sqrt{\frac{2}{\pi T}} \mathbb{E}\left[\exp\left(-\frac{T^{3/2}}{2} \left( \int_0^1 \frac{r_t \, dt}{\Lambda_{\beta}^1(r)} - \int_0^\infty \frac{L_{\beta}^0(r)^2}{2} \, da\right) - T^{1/2} w \frac{L_{\beta}^0(0)^2}{2}\right]\right],$$

where $r_t, t \in [0,1]$ is a reflected Brownian bridge.

Since the density of $L_{\beta}^0(r)$ is known (see e.g. [21], equation (3)), it suffices to find the conditional distribution of the functional

$$\int_0^1 r_t \, dt - \int_0^\infty \frac{L_{\beta}^0(r)^2}{\beta} \, da$$

given $L_{\beta}^0(r)$ to compute the right-hand side in (1.22). For $\beta = 2$, this leads to the following theorem of independent interest.
Theorem 1.11. Let \( r_t, t \in [0,1] \) be a reflected Brownian bridge. Then, for every \( \alpha \geq 0 \), the conditional distribution of the functional
\[
\int_0^1 r_t \, dt - \int_0^\infty \frac{L_1^2(r)}{2} \, da
\]
given \( L_0^1(r) = \alpha \) is Gaussian with mean \(-\alpha/4\) and variance \(1/12\).

Remark 1.12. Conditional on \( L_0^1(r) = 0 \), the process \( r_t, t \in [0,1] \) is a standard Brownian excursion, so that Theorem 1.11 is a generalization of the distributional identity for the latter found in [13, Corollary 2.15] (see also [14, Theorem 1.1]).

As a consequence of Theorem 1.11, we obtain an explicit formula for \( \mathbb{E}[K^{2w}_T(0,0)] \).

Corollary 1.13. For any \( w \in \mathbb{R} \) and \( T > 0 \), and with
\[
C_{w:T} := \sqrt{T(T - 4w)/4\sqrt{2}},
\]
it holds
\[
\mathbb{E}[K^{2w}_T(0,0)] = \sqrt{\frac{2}{\pi T}} \exp \left( \frac{T^3}{96} \right) \left( 1 + \sqrt{T} C_{w:T} \exp \left( C_{w:T}^2 \right) \right) \left( \text{erf}(C_{w:T}) + 1 \right),
\]
where \( \text{erf}(z) := \frac{2}{\sqrt{\pi}} \int_0^z e^{-a^2} \, da \) denotes the error function.

For \( \beta \neq 2 \), we were not able to obtain an analogue of Theorem 1.11.

Open Problem 1.14. Find the conditional distribution of the functional in (1.23) given \( L_0^1(r) \) for all \( \beta > 0 \).

Remark 1.15. A simple computation based on Theorem 1.11 shows that the unconditional distribution of the random variable
\[
A := \sqrt{12} \left( \int_0^1 r_t \, dt - \int_0^\infty \frac{L_1^2(r)}{2} \, da \right)
\]
has a moment-generating function given by
\[
\mathbb{E}[\exp(\kappa A)] = \exp \left( \frac{\kappa^2}{2} \right) - \sqrt{\frac{3}{2}} \kappa \exp \left( \frac{\kappa^2}{2} \right) \text{erfc} \left( \sqrt{\frac{3}{2}} \kappa \right),
\]
where \( \text{erfc}(z) := \frac{2}{\sqrt{\pi}} \int_z^\infty e^{-a^2} \, da \) denotes the complementary error function. Therefore, it seems natural to view the density of \( A \) as a sum of the standard Gaussian density and a function that integrates to 0, which yields a corresponding decomposition of the moments of \( A \) (see Table 1 for the first few moments). In particular, Table 1 suggests the following formula for the odd moments of \( A \):
\[
\mathbb{E}[A^{2n-1}] = -\frac{2^n(2n-1)!}{4(n-1)!} \sqrt{6\pi}, \quad n = 1, 2, \ldots,
\]
leading us to believe that \( A \) admits an interesting combinatorial interpretation.

The remainder of the paper is structured as follows. In Section 2, we prove a strong invariance principle for certain non-negative random walks and their families of occupation times, which plays a central role in the proof of Theorem 1.7. The proof of the invariance principle is based on the observation that the non-negative random walks in consideration can be viewed as images of simple random walks.
Moreover, for each \( n \in \mathbb{N}_0 \) and \( k \in \mathbb{R}_+ \), we introduce the normalized occupation times of \( X \) conditioned on its local time at zero from \([22, Corollary 16(iii)]\).

In Section 2 we show the properties of the limiting operators \( L_{T,N}^{\beta,w} \), \( T \geq 0 \) listed in Proposition 1.8. Lastly, in Section 5 we establish Theorem 1.11 as well as Proposition 1.10 and Corollary 1.13. The proof of Theorem 1.11 combines the ideas of [14] with the analogue of Jeulin’s theorem for a reflected Brownian bridge conditioned on its local time at zero from [22 Corollary 16(iii)].

### 2. A strong invariance principle

This section focuses on the strong invariance principle for certain non-negative random walks and their families of occupation times, which is at the heart of the proof of Theorem 1.7. For starters, we let \( Y = (Y_0, Y_1, \ldots) \) be a random walk on the non-negative integers with transition probabilities

\[
\begin{align*}
P[Y_{n+1} = z + 1 \mid Y_n = z] &= P[Y_{n+1} = z - 1 \mid Y_n = z] = \frac{1}{2}, \quad z = 1, 2, \ldots, \\
\quad P[Y_{n+1} = 1 \mid Y_n = 0] &= P[Y_{n+1} = 0 \mid Y_n = 0] = \frac{1}{2}.
\end{align*}
\]

In other words, when \( Y \) is away from 0, it behaves like a simple symmetric random walk (SSRW), and when \( Y \) is at 0, it stays at 0 or moves to 1 with equal probability.

Given \( T > 0 \) and \( N \in \mathbb{N} \), we let \( k = k(T,N) := \lfloor TN^{-2/3} \rfloor \) and \( T_k := kN^{-2/3} \). Moreover, for each \( x \geq 0 \), we define a process \( X_t^{k,x} \), \( t \in [0,T_k] \) satisfying

\[
(X_0^{k,x}, X_{N^{-2/3}}^{k,x}, \ldots, X_{T_k}^{k,x}) \overset{d}{=} (Y_0, Y_1, \ldots, Y_k \mid Y_0 = \lfloor xN^{1/3} \rfloor)
\]

and interpolating linearly between these time points (see Figure 1 for an illustration). We also introduce the normalized occupation times of \( X^{k,x} \) for positive levels:

\[
L^a(X^{k,x}) := N^{-1/3}\{t \in [0,T_k] : X^{k,x} = aN^{1/3}\}, \quad a > 0
\]

The first few moments of \( Y \) are as follows:

| \( E[A] \) | \( -\sqrt{6\pi}/2 \) | \( E[A^8] \) | 105 + 85032 |
| \( E[A^2] \) | \( 1 + 6 \) | \( E[A^9] \) | \( -120960\sqrt{6\pi} \) |
| \( E[A^3] \) | \( -6\sqrt{6\pi} \) | \( E[A^{10}] \) | 945 + 3404430 |
| \( E[A^4] \) | \( 3 + 108 \) | \( E[A^{11}] \) | \( -5322240\sqrt{6\pi} \) |
| \( E[A^5] \) | \( -120\sqrt{6\pi} \) | \( E[A^{12}] \) | 10395 + 163446660 |
| \( E[A^6] \) | \( 15 + 2646 \) | \( E[A^{13}] \) | \( -276756480\sqrt{6\pi} \) |
| \( E[A^7] \) | \( -3360\sqrt{6\pi} \) | \( E[A^{14}] \) | 135135 + 9153449550 |

under the Skorokhod reflection map, and we expect the same idea to apply for a wide variety of constrained discrete processes. Section 3 is devoted to the proof of Theorem 1.7. The proof has the following general structure: first, we write the entries of the matrix \( M_{T,N}^{\beta,w} \) as expectations of suitable functionals of the non-negative random walks of Section 2 and the entries of the matrix \( M_{N}^{\beta,w} \); then, we derive the limiting behavior of suitably truncated versions of such expectations using the strong invariance principle of Section 2 finally, we remove the truncation by obtaining appropriate uniform moment estimates on the functionals involved.
and use the convention
\[ (2.4) \quad L^0(X^{k,x}) := \lim_{\alpha \downarrow 0} L^\alpha(X^{k,x}). \]

Finally, we let
\[ (2.5) \quad H(X^{k,x}) := \left| \{ t \in [0,T_k] \cap N^{-2/3}N : X^{k,x}_{t-N^{-2/3}} = X^{k,x}_t = 0 \} \right| \]
be the number of the horizontal steps at zero in \((X^{k,x}_0, X^{k,x}_{N^{-2/3}}, \ldots, X^{k,x}_{T_k})\). Our strong invariance principle can now be stated as follows.

\vspace{1cm}

**Figure 1.** A sample path of \(X^{k,x}\) with \(k = 28\) and \([xN^{1/3}] = 3\).

**Theorem 2.1.** For every \(T > 0\) and \(x \geq 0\), there exists a coupling of the sequence of processes \(X^{k,x}, N \in \mathbb{N}\) and a reflected Brownian motion \(R^x\) such that
\[ (2.6) \quad \sup_{t \in [0,T]} \left| N^{-1/3} X^{k,x}_t - R^x_t \right| \leq CN^{-1/3} \log N, \quad N \in \mathbb{N}, \]
\[ (2.7) \quad \sup_{\alpha > 0} \left| L^\alpha(X^{k,x}) - L^\alpha(R^x) \right| \leq CN^{-1/16}, \quad N \in \mathbb{N}, \]
\[ (2.8) \quad \left| N^{-1/3} H(X^{k,x}) - L^0_T(R^x)/2 \right| \leq CN^{-1/3} \log N, \quad N \in \mathbb{N}, \]
where \(C\) is a suitable finite random variable.

A direct construction of the coupling in Theorem 2.1 appears to be difficult. Instead, our proof of Theorem 2.1 relies on the Komlós-Major-Tusnády coupling of a SSRW with a standard Brownian motion and an application of the Skorokhod reflection map. We briefly recall the definition and some properties of the latter.

**Definition 2.2.** Given a \(T > 0\) and a continuous process \(Z_t, t \in [0,T]\), we define the Skorokhod map evaluated at \(Z\) as the continuous process
\[ (2.9) \quad \Gamma(Z)_t = Z_t + \sup_{s \in [0,t]} (-Z_s)_+, \quad t \in [0,T], \]
where \((- \cdot)_+ := \max(0, \cdot)\) denotes the positive part of a real number.

A reflected Brownian motion \(R^x\) can be defined by \(R^x = |x + \tilde{W}|\), where \(\tilde{W}\) is a standard Brownian motion. According to Tanaka’s formula (see e.g. [24], Chapter VI, Theorem 1.2) one has
\[ (2.10) \quad R^x_t = x + \int_0^t \text{sgn}(\tilde{W}_s) \, d\tilde{W}_s + L^{-x}_t(\tilde{W}), \quad t \in [0,T]. \]
Furthermore, if we let
\begin{equation}
B^e_t := x + \int_0^t \text{sgn}(W_s) \, dW_s, \quad t \in [0, T],
\end{equation}
which is a Brownian motion started at \(x\), then it follows from a classical result of
Skorokhod [24] Chapter VI, Lemma 2.1 and Corollary 2.2 that
\begin{equation}
\frac{R_t^e}{t} = B^e_t + \sup_{s \in [0, t]} (-B^e_s)_+, \quad t \in [0, T],
\end{equation}
\begin{equation}
\sup_{s \in [0, t]} (-B^e_s)_+ = L_t(x + W) = L_t^0(x + \tilde{W}) = \frac{L_t^0(R^e)}{2}, \quad t \in [0, T].
\end{equation}

We give in the next proposition a discrete analogue of these results.

**Proposition 2.3.** Let \(\tilde{Y} = (\tilde{Y}_0, \tilde{Y}_1, \ldots)\) be a SSRW and define the process \(\tilde{X}^{k,x}\), \(t \in [0, T_k]\) by using the same procedure as for \(X^{k,x}\) (that is, equation (2.12) followed by a linear interpolation), but with with the SSRW \(\tilde{Y}\) instead of the random walk \(Y\). Then, \(Y\) and \(\tilde{Y}\) can be coupled in such a way that \(X^{k,x}_t = \Gamma(\tilde{X}^{k,x}_t), t \in [0, T_k]\) and \(H(X^{k,x}) = \sup_{t \in [0, T_k]} (-\tilde{X}^{k,x}_t)_+\).

**Proof.** Both \(X^{k,x}\) and \(\tilde{X}^{k,x}\) can take a total of \(2^k\) possible sample paths, and the measures that \(Y\) and \(\tilde{Y}\) induce on these paths are uniform in both cases. Therefore, we need to show that \(\Gamma\) is a bijection taking paths of \(\tilde{X}^{k,x}\) to paths of \(X^{k,x}\) and that \(H(\Gamma(\tilde{X}^{k,x})) = \sup_{t \in [0, T_k]} (-\tilde{X}^{k,x}_t)_+\).

Whenever \(\min \tilde{X}^{k,x} \geq 0\), the Skorokhod map \(\Gamma\) leaves \(\tilde{X}^{k,x}\) unchanged, and trivially \(H(\Gamma(\tilde{X}^{k,x})) = 0 = \sup_{t \in [0, T_k]} (-\tilde{X}^{k,x}_t)_+\). On the other hand, whenever \(\min \tilde{X}^{k,x} < 0\), the application of \(\Gamma\) can be described as follows (see Figure 2 below): (a) one determines the first hitting times \(\tau_{-1} < \tau_{-2} < \cdots\) of the negative integer levels by \(\tilde{X}^{k,x}\);
(b) one sets \(\Gamma(\tilde{X}^{k,x})_t := \tilde{X}^{k,x}_t\) for \(t \in [0, \tau_{-1} - N^{-2/3}]\);
(c) for \(j = 1, 2, \ldots\), \(-\min \tilde{X}^{k,x}\), one lets \(\Gamma(\tilde{X}^{k,x})_t := 0\) for \(t \in (\tau_{-j} - N^{-2/3}, \tau_{-j})\);
(d) for \(j = 1, 2, \ldots\), \(-\min \tilde{X}^{k,x} - 1\), one defines \(\Gamma(\tilde{X}^{k,x})_t := \tilde{X}^{k,x}_t + j\) for \(t \in (\tau_{-j} - N^{-2/3}, \tau_{-j})\);
(e) one puts \(\Gamma(\tilde{X}^{k,x})_t := \tilde{X}^{k,x}_t - \min \tilde{X}^{k,x}\) for \(t \in (\tau_{\min \tilde{X}^{k,x}}, T_k]\).

It follows immediately from this description that the horizontal steps at zero in \((\Gamma(\tilde{X}^{k,x})_0, \Gamma(\tilde{X}^{k,x})_{N^{-2/3}}, \ldots, \Gamma(\tilde{X}^{k,x})_{T_k})\) occur at \(\tau_{-1} - N^{-2/3}, \tau_{-2} - N^{-2/3}, \ldots, \tau_{\min \tilde{X}^{k,x}} - N^{-2/3}\), so that \(H(\Gamma(\tilde{X}^{k,x})) = -\min \tilde{X}^{k,x} = \sup_{t \in [0, T_k]} (-\tilde{X}^{k,x}_t)_+\). Moreover, for every path of \(X^{k,x}\), one can uniquely reconstruct the corresponding path \(\Gamma^{-1}(X^{k,x}) = \tilde{X}^{k,x}\) by inferring the sequence \(\tau_{-1} < \tau_{-2} < \cdots\) from the horizontal segments in the path of \(X^{k,x}\), solving the equations in (b), (d), (e) above, and inserting the remaining \(H(X^{k,x})\) downward sloping segments. \(\square\)

Next, we prepare another coupling needed for the proof of Theorem 2.1.

**Lemma 2.4.** For every \(T > 0\) and \(x \geq 0\), there exists a coupling of the sequence of processes \(X^{k,x}, N \in \mathbb{N}\) defined in Proposition 2.3 and a standard Brownian motion \(B\) such that
\begin{equation}
\sup_{t \in [0, T_k]} |N^{-1/3}\tilde{X}^{k,x}_t - (x + B_t)| \leq CN^{-1/3} \log N, \quad N \in \mathbb{N},
\end{equation}
where \( C \) is a suitable finite random variable.

**Proof.** Consider a probability space which supports a standard Brownian motion \( B \) and define the standard Brownian motions

\[
B_t^{(N)} := N^{1/3}B_{tN^{-2/3}}, \quad t \geq 0
\]

for all \( N \in \mathbb{N} \). According to a well-known procedure of Komlós, Major and Tusnády (see e.g. [19, Section 7]), one can construct random walks \((\tilde{Y}_0^{(N)}, \tilde{Y}_1^{(N)}, \ldots), N \in \mathbb{N}\) as deterministic functions of the Brownian motions \(B^{(N)}, N \in \mathbb{N}\), respectively, such that for every \( \alpha > 0 \), there exists a \( C < \infty \) so that

\[
P\left[ \max_{0 \leq n \leq k} |\tilde{Y}_n^{(N)} - B_n^{(N)}| \geq C \log N \right] \leq CN^{-\alpha}, \quad N \in \mathbb{N}.
\]

As a result, we can couple the sequence \( \tilde{X}^{k;x}, N \in \mathbb{N} \) with \( B \) ensuring

\[
P \left[ \max_{0 \leq i \leq k} |N^{-1/3}X_{N^{-2/3}i}^{k;x} - B_{N^{-2/3}i}| \geq CN^{-1/3} \log N \right] \leq CN^{-\alpha}, \quad N \in \mathbb{N}.
\]

Lastly, we let \( \alpha > 1 \) and conclude by applying the Borel-Cantelli lemma and the Lévy modulus of continuity theorem. \( \square \)

Finally, we define the random walk \( \mathbf{Y} = (\mathbf{Y}_0, \mathbf{Y}_1, \ldots) \) on the integers, to be used in the proof of Theorem [2.1] by

\[
P[\mathbf{Y}_{n+1} = z + 1 | \mathbf{Y}_n = z] = P[\mathbf{Y}_{n+1} = z - 1 | \mathbf{Y}_n = z] = \frac{1}{2}, \quad z \in \mathbb{Z}\setminus\{0\},
\]

\[
P[\mathbf{Y}_{n+1} = 1 | \mathbf{Y}_n = 0] = P[\mathbf{Y}_{n+1} = -1 | \mathbf{Y}_n = 0] = \frac{1}{4}, \quad P[\mathbf{Y}_{n+1} = 0 | \mathbf{Y}_n = 0] = \frac{1}{2}.
\]

For every \( n \in \mathbb{N} \), we let

\[
H_n(\mathbf{Y}) = |\{1 \leq i \leq n : \mathbf{Y}_{i-1} = \mathbf{Y}_{i} = 0\}|
\]
be the number of the horizontal steps at zero among the first $n$ steps of $\overline{Y}$ and define $v(\overline{Y})_n$, $n = 0, 1, \ldots$ as the process obtained from $\overline{Y}$ by removing all the horizontal steps at zero, so that

$$v(\overline{Y})_n = v(\overline{Y})_{n-H_n(\overline{Y})}, \quad n = 0, 1, \ldots.$$  \hfill (2.20)

We also introduce, for $m \in \mathbb{N}$, $T > 0$ and $a \neq 0$, the normalized occupation times

$$L^a_{m,T}(\overline{Y}) := m^{-1/2} \left| \left\{ 0 \leq t \leq mT : Y_t = \sqrt{ma} \right\} \right|.$$  \hfill (2.21)

where we define $\overline{Y}$ for non-integer times by linear interpolation. Lastly, we let $L^a_{m,T}(v(\overline{Y}))$ be given by (2.21) with $v(\overline{Y})$ in place of $\overline{Y}$.

**Remark 2.5.** By examining the transition probabilities of $\overline{Y}$ it becomes clear that $v(\overline{Y})_n$, $n = 0, 1, \ldots$ is a SSRW, and that $Y$ and $\overline{Y}$ can be coupled to obey

$$|\overline{Y}_n| = Y_n, \quad n = 0, 1, \ldots,$$

(2.22)

provided the two processes have the same starting point. If we condition on the starting point $Y_0 = \overline{Y}_0 = \lfloor N^{1/3} \rfloor$, then it holds under this coupling that

$$L^a(X^{k,x}) = L^a_{N^{2/3},T}(\overline{Y}) + L^a_{N^{2/3},T}(\overline{Y}), \quad a > 0.$$  \hfill (2.23)

We conclude the section with the proof of Theorem 2.1.

**Proof of Theorem 2.1.** The maps $\Gamma$ and $f \mapsto \sup_{t \in [0,T]} (-f(t))_+$ are $2$-Lipschitz and $1$-Lipschitz with respect to the supremum norm, respectively, so that (2.6) and (2.8) follow from (2.14) by combining Proposition 2.3 with (2.12) and (2.13), respectively.

The remaining estimate (2.7) is a consequence of the estimate (2.6) and the regularity of the local time processes involved. More specifically, by using the same arguments as in [13, Appendix B] (note that $a \mapsto L^a_T(R^x)$ inherits the regularity properties of $a \mapsto L^a_T(W)$ due to $R^x = |x + W|$), we can reduce (2.7) to the following statement: for every $\varepsilon > 0$, there exists a finite random variable $C_1$ such that

$$\sup_{a_1, a_2 > 0} \sup_{|a_1 - a_2| \leq N^{-2/15}} \left| L^a_{N^{2/3},T}(\overline{Y}) - L^a_{N^{2/3},T}(\overline{Y}) \right| \leq C_1 N^{-1/15 + \varepsilon}, \quad N \in \mathbb{N}$$

(2.24)

(cf. [13, Lemma B.3]). To this end and in view of (2.23), it suffices to prove that

$$\sup_{a_1, a_2 \in \mathbb{R} \setminus \{0\}} \sup_{|a_1 - a_2| \leq N^{-2/15}} \left| L^a_{N^{2/3},T}(v(\overline{Y})) - L^a_{N^{2/3},T}(v(\overline{Y})) \right| \leq C_2 N^{-1/15 + \varepsilon}, \quad N \in \mathbb{N}.$$  \hfill (2.25)

Applying [3, Proposition 3.1] to the SSRW $v(\overline{Y})$ we get

$$\sup_{t \in [0,T]} \sup_{a_1, a_2 \in \mathbb{R} \setminus \{0\}} \sup_{|a_1 - a_2| \leq N^{-2/15}} \left| L^a_{N^{2/3},T}(v(\overline{Y})) - L^a_{N^{2/3},T}(v(\overline{Y})) \right| \leq C_2 N^{-1/15 + \varepsilon}, \quad N \in \mathbb{N},$$  \hfill (2.26)

at which point the desired estimate (2.25) follows from (2.20). \hfill \Box

3. **Proof of Theorem 1.7**

This section is devoted to the proof of Theorem 1.7. Since the proof is rather long, we first present an informal overview of the arguments in Subsection 3.1 before rigorously carrying out the proof in Subsections 3.2 and 3.3.
3.1. Informal overview of the proof. Let $\beta > 0$, $w \in \mathbb{R}$, $T > 0$ and $f, g \in \mathcal{D}$ be fixed. Our object of study is the scalar product

$$ (\pi_N f) \mathcal{M}^{\beta,w}_{T,N} (\pi_N g) = \sum_{l, l' = 0}^{N} (\pi_N f)[l] \cdot \mathcal{M}^{\beta,w}_{T,N}[l, l'] \cdot (\pi_N g)[l'].$$

Here and throughout the paper, we index all $(N + 1) \times (N + 1)$ matrices $A$ by $l, l' \in \{0, 1, \ldots, N\}$ and write $A[l, l']$ for the $(l, l')$-entry of $A$. Similarly, the entries of all $(N + 1)$-dimensional vectors $v$ are denoted by $v[l]$ for $l \in \{0, 1, \ldots, N\}$. By the definition of $\pi_N$ in (1.10), we then see that

$$ (\pi_N f) \mathcal{M}^{\beta,w}_{T,N} (\pi_N g) = \int_{0}^{N^{2/3}} \int_{0}^{N^{2/3}} f(x) K^{\beta,w}_{T,N}(x, y) g(y) \, dx \, dy, $$

where

$$ K^{\beta,w}_{T,N}[l, l'] = \sum_{j = 0}^{N} N^{1/3} \mathcal{M}^{\beta,w}_{T,N}[l, l'] \mathbb{1}_{[N^{-1/3}(l, N^{-1/3}(l + 1)) \times [N^{-1/3}(l', N^{-1/3}(l' + 1))]}, $$

Recalling $k = k(T, N) = [TN^{2/3}]$ and the definition of $\mathcal{M}^{\beta,w}_{T,N}$ in (1.10), we find for all $l, l' \in \{0, 1, \ldots, N\}$:

$$ \mathcal{M}^{\beta,w}_{T,N}[l, l'] = \frac{1}{(2\sqrt{N})^k} \sum_{0 \leq l_0, \ldots, l_k \leq N} \mathcal{M}^{\beta,w}_{N}[l_0, l_1] \mathcal{M}^{\beta,w}_{N}[l_1, l_2] \cdots \mathcal{M}^{\beta,w}_{N}[l_{k-1}, l_k]. $$

Since $\mathcal{M}^{\beta,w}_{N}$ is tridiagonal, only $(k + 1)$-tuples $(l_0, l_1, \ldots, l_k)$ that satisfy $l_0 = l$, $l_k = l'$ and $|l_{s-1} - l_s| \in \{0, 1\}$ for all $s$ contribute to $\mathcal{M}^{\beta,w}_{T,N}[l, l']$. Any such $(k + 1)$-tuple can be thought of as a path from $l_0$ to $l_k$ that takes steps of size $+1$ or $-1$ (when $|l_{s-1} - l_s| = 1$), and horizontal steps (when $l_{s-1} - l_s = 0$). In the following, we rely on this observation to write the sum on the right-hand side of (3.2) in terms of expectations with respect to the random walks of Section 2.

For $j = 0, 1, \ldots$ and $x \geq 0$, we define the random walk $X^{k-j,x}$, its normalized occupation times and its number of horizontal steps at zero by (2.2)–(2.5), with $(k - j)$ in place of $k$. We also let $ar{X}_t^{k-j,x}$, $t \in [0, T_{k-j} - N^{-2/3}H(X^{k-j,x})]$ be the path obtained from $X_t^{k-j,x}$, $t \in [0, T_{k-j}]$ by removing all horizontal segments at zero (see Figure 3). Finally, we introduce the functional

$$ F_j(X^{k-j,x}, a, \xi) := \prod_{i=1}^{k-j-H(X^{k-j,x})} \frac{N - \bar{X}_N^{k-j,x}}{\bar{X}_N^{k-j,x}} \frac{\mathcal{N}_{N-2/3}^{k-j,x}(i-1) \wedge \bar{X}_N^{k-j,x}}{\bar{X}_N^{k-j,x}} \left(1 + \frac{\xi \mathcal{N}_{N-2/3}^{k-j,x}(i-1) \wedge \bar{X}_N^{k-j,x}}{\mathcal{N}_{N-2/3}^{k-j,x}(i-1) \wedge \bar{X}_N^{k-j,x}} \right) \mathcal{H}(X^{k-j,x}) \left(\frac{1}{(2\sqrt{N})^j} \sum_{0 \leq i_1 \leq \cdots \leq i_j \leq k} a_{i_1, \ldots, i_j} \mathcal{N}_{N-2/3}^{k-j,x}(i_1) \wedge \bar{X}_N^{k-j,x} \right), $$

where the random walk $X^{k-j,x}$ is independent of all $a_m$'s and $\xi_k$'s.
Figure 3. Realizations of $X^{k-j;x}$ (top) and $\hat{X}^{k-j;x}$ (bottom).

If $x \in \left[ N^{-1/3}l, N^{-1/3}(l+1) \right]$ and $y \in \left[ N^{-1/3}l', N^{-1/3}(l'+1) \right]$, then by definition of $M_{T;N}^{\beta;w}$, one has

$$M_{T;N}^{\beta;w}(l,l') = \sum_{j=0}^{k} \frac{Q_{x,y}^{k-j}}{2^{k-j}} E_{X^{k-j;x}} \left[ F_j \left( X^{k-j;x}, a, \xi \right) \mid X^{k-j;x}_{T_{k-j}} = \lfloor N^{1/3}y \rfloor \right],$$

with $Q_{x,y}^{k-j}$ being the number of paths $X^{k-j;x}$ can take such that $X^{k-j;x}_{T_{k-j}} = \lfloor N^{1/3}y \rfloor$, or equivalently,

$$Q_{k-j}^{x,y} := 2^{k-j} P \left[ X^{k-j;x}_{T_{k-j}} = \lfloor N^{1/3}y \rfloor \right].$$

In the above, the parameter $j$ represents the number of times it holds $l_{s-1} = l_s \neq 0$ within a $(k+1)$-tuple $(l_0, l_1, \ldots, l_k)$. Removing the corresponding horizontal steps from the associated path leaves us with a path of $X^{k-j;x}$. At the same time, the term in the third line of (3.3) keeps track of all the possible ways $j$ horizontal steps away from zero can be inserted into a given realization of $X^{k-j;x}$. Finally, the term $Q_{k-j}^{x,y}$ arises from the normalization inherent to the conditional expectation $E_{X^{k-j;x}} \cdot \left[ X^{k-j;x}_{T_{k-j}} = \lfloor N^{1/3}y \rfloor \right]$.

Next, we let

$$(3.6) \quad Sc_k(f, g) := \int_0^{N^{2/3}} \int_0^{N^{2/3}} N^{1/3} f(x) \cdot \frac{Q_{k-j}^{x,y}}{2^{k-j}} E_{X^{k-j;x}} \left[ F_j \left( X^{k-j;x}, a, \xi \right) \mid X^{k-j;x}_{T_{k-j}} = \lfloor N^{1/3}y \rfloor \right] g(y) \, dx \, dy,$$
We also note that, by the total probability rule, 
(3.8) \[ S_{j}^{(f,g)} = \int_{0}^{N^{2/3}} f(x) E_{X^{k-j,x}} [F_{j}(X^{k-j,x}, a, \xi) \cdot N^{1/3} \int_{N^{-1/3}X^{k-j,x}}^{N^{-1/3}X^{k-j,x}+1} g(y) \, dy] \, dx, \]

\( j = 0, 1, \ldots \) The proof of Theorem 1.7 now hinges on justifying the following heuristic computation.

**Heuristic computation 3.1.** We recall the strong invariance principle of Theorem 2.1. Since \( \log(1+z) = z + O(z^{2}) \) when \( z \approx 0 \), we have for \( j = 0, 1, \ldots \) that

\[
\begin{align*}
& k-j-H(X^{k-j,x}) \prod_{i=1}^{k-j-H(X^{k-j,x})} \left( 1 + \frac{\xi \hat{X}^{k-j,x}_{N^{-2/3}(i-1)} \wedge \hat{X}^{k-j,x}_{N^{-2/3}}}{\sqrt{N}} \right) \\
& = \prod_{i=1}^{k-j-H(X^{k-j,x})} \left( 1 + \xi \hat{X}^{k-j,x}_{N^{-2/3}(i-1)} \wedge \hat{X}^{k-j,x}_{N^{-2/3}} \right) \left( 1 - \frac{\hat{X}^{k-j,x}_{N^{-2/3}(i-1)} \wedge \hat{X}^{k-j,x}_{N^{-2/3}}}{N} \right)^{-1/2} \\
& \approx \exp \left( - \int_{0}^{T} R_{t} \, dt \right), \quad N \to \infty.
\end{align*}
\]

At the same time, \( (1-z)^{1/2} = 1 + O(z) \) when \( z \approx 0 \) suggests for \( j = 0, 1, \ldots \) that

\[
\begin{align*}
& k-j-H(X^{k-j,x}) \prod_{i=1}^{k-j-H(X^{k-j,x})} \left( 1 + \frac{\xi \hat{X}^{k-j,x}_{N^{-2/3}(i-1)} \wedge \hat{X}^{k-j,x}_{N^{-2/3}}}{\sqrt{N}} \right) \\
& = \prod_{i=1}^{k-j-H(X^{k-j,x})} \left( 1 + \xi \hat{X}^{k-j,x}_{N^{-2/3}(i-1)} \wedge \hat{X}^{k-j,x}_{N^{-2/3}} \right) \left( 1 - \frac{\hat{X}^{k-j,x}_{N^{-2/3}(i-1)} \wedge \hat{X}^{k-j,x}_{N^{-2/3}}}{N} \right)^{-1/2} \\
& \approx \exp \left( - \int_{0}^{T} R_{t} \, dt \right), \quad N \to \infty.
\end{align*}
\]
as \( N \to \infty \), where \( W^\xi \) is the Brownian motion arising from a Donsker type invariance principle for the sequence \( \xi_0, \xi_1, \ldots \) (see (3.20) below). Moreover,

\[
\ell_N^{H(X^{k-j};x)} = \left( 1 - \frac{N^{1/3} (1 - \ell_N)}{N^{1/3}} \right)^{N^{1/3} \langle H(X^{k-j};x) \rangle / N^{1/3}} \ \to \ \exp \left( -\frac{L_0^a(R^\xi)}{2} \right), \quad N \to \infty,
\]

for \( j = 0, 1, \ldots \).

Next, we consider \( j = 2 \) and make the simple observation

\[
\frac{1}{N} \sum_{0 \leq i_1 \leq i_2 \leq k} a_{X_{N-2/3,i_1}} a_{X_{N-2/3,i_2}} = \frac{1}{2N} \left( \sum_{i=0}^k a_{X_{N-2/3,i}} \right)^2 + \frac{1}{2N} \sum_{i=0}^k a_{X_{N-2/3,i}}^2.
\]

In addition, from \( k = O(N^{2/3}) \) and Assumption \( \text{[1.2]} \) we infer that the second summand on the right-hand side of (3.12) is negligible in the limit \( N \to \infty \). Similar reasoning for \( j = 3, 4, \ldots \) reveals that, for all \( j = 1, 2, \ldots \), as \( N \to \infty \),

\[
\frac{1}{(2\sqrt{N})^j} \sum_{0 \leq i_1 \leq \ldots \leq i_j \leq k} \prod_{j'=1}^j a_{X_{N-2/3,i_j}} \approx \frac{1}{j! (2\sqrt{N})^j} \left( \sum_{i=0}^k a_{X_{N-2/3,i}} \right)^j \to \frac{1}{j! 2^j} \left( s_0^a \int_0^\infty L^a_T(R^\xi) \, dW^a \right)^j,
\]

where \( W^a \) is the Brownian motion in a Donsker type invariance principle for the sequence \( a_1, a_2, \ldots \) (see (3.20) below).

Finally, the Lebesgue differentiation theorem suggests that

\[
N^{1/3} \int_{N^{-1/3} X_{N-2}^{k-j};x}^{N^{-1/3} (X_{N-2}^{k-j};x+1)} g(y) \, dy \to g(R^\xi_T), \quad N \to \infty.
\]

All in all, we expect that, for each \( j = 0, 1, \ldots \), the quantity \( S_{L_k}^j(f,g) \) converges, as \( N \to \infty \), to

\[
\int_0^\infty f(x) \mathbf{E}_{R^\xi} \left[ \exp \left( -\int_0^T \frac{R^\xi_t}{2} \, dt + s_\xi \int_0^\infty L^a_T(R^\xi) \, dW^\xi_a - \frac{L_0^a(R^\xi)}{2} \right) \right] \frac{1}{j!} \left( s_0^a \int_0^\infty L^a_T(R^\xi) \, dW^a \right)^j g(R^\xi_T) \, dx.
\]

Summing over \( j = 0, 1, \ldots \) and letting \( W := \sqrt{\beta} (s_\xi W^\xi + a^a W^a) \) we end up precisely with the right-hand side of (1.17).

### 3.2. Truncated convergence

Our first step in the rigorous proof of Theorem \( \text{[1.7]} \) consists in establishing a convergence result for truncated versions of \( S_{L_k}^j(f,g) \), \( j = 0, 1, \ldots \). To this end, we define for all \( S \in [-\infty, 0] \) and \( \overline{S} \in [0, \infty] \) the truncated
and introduce the limiting operators

\[ \lim_{N \to \infty} \sqrt{\frac{N - X_{N-2/3}(i - 1)}{N}} \]

for all \( K \in \mathbb{N} \cup \{0, \infty\} \) the truncated functions \( f_K = f h_K \) and \( g_K = g h_K \), where the continuous \( h_K : [0, \infty) \to [0, 1] \) satisfy \( h_K \equiv 1 \) on \([0, K]\) and \( h_K \equiv 0 \) on \([2K, \infty)\).

**Remark 3.2.** Note that, apart from the truncation at \( g \), any finite collection of \( j \)'s enter into them.

We now truncate the terms \( S c_k^j(f, g) \), \( j = 0, 1, \ldots \) according to

\[ S c_k^j(f, g; \Sigma, \tilde{\Sigma}) \]

and introduce the limiting operators

\[ (U_{T, j}^{\Sigma, \tilde{\Sigma}}) f(x) := E_{R^*} \left( \Sigma \vee \exp \left( - \int_0^T \frac{R^e}{2} \, dt + s \xi \int_0^\infty L_0^e (R^e) \, dW_0^\xi - \frac{L_0^e (R^e)}{2} \right) \right) \]

for \( f \in D \) and \( j = 0, 1, \ldots \).

**Proposition 3.3.** Let \( \Sigma, \tilde{\Sigma} \) and \( K \) be finite. Then, for all functions \( f \in D \) and \( g \in D \cap C([0, \infty)) \),

\[ \lim_{N \to \infty} \frac{a_m}{N^{1/6}} \sum_{n=0}^{N^{1/2} x} = s_x W_x^a \]

in distribution and in the sense of moments. These convergences hold jointly for any finite collection of \( j \)'s, \( T \)'s, \( f \)'s and \( g \)'s, and in the case of the convergence in distribution also jointly with the convergences in distribution

\[ \lim_{N \to \infty} \sum_{m=0}^{N^{1/2} x} \frac{\xi_m}{N^{1/6}} = s_x W_x^\xi \]

with respect to the Skorokhod topology.
The key ingredient in the proof of Proposition 3.3 is the next lemma. Therein and henceforth, for probability measures \( \mu \) on \([0, \infty)\), we use the notations \( X^{k; \mu} \) and \( R^\mu \) for the random walk \( X^{k; x} \) started according to the image of \( \mu \) under the map \( x \mapsto \lfloor xN^{1/3} \rfloor \) and the reflected Brownian motion \( R^x \) started according to \( \mu \), respectively.

**Lemma 3.4.** Let \( n \in \mathbb{N} \) and \( \mu_1, \mu_2, \ldots, \mu_n \) be probability measures on \([0, \infty)\). Then, there exists a coupling of independent \( X^{k; \mu_1}, X^{k; \mu_2}, \ldots, X^{k; \mu_n} \) with independent \( R^{\mu_1}, R^{\mu_2}, \ldots, R^{\mu_n} \) such that the following limits in distribution hold jointly over \( l = 1, 2, \ldots, n \), and also jointly with (3.20),

\[
\begin{align*}
(3.21) & \quad \lim_{N \to \infty} \sup_{t \in [0, T_N]} |N^{-1/3} X_t^{k; \mu_l} - R_t^{\mu_l}| = 0, \\
(3.22) & \quad \lim_{N \to \infty} \sum_{a \in N^{1/3}(n-1/2)} L^a(X^{k; \mu_l}) \frac{\xi_{[N^{1/3}a]}}{N^{1/6}} = s \int_0^\infty L^a_T(R^{\mu_l}) \, dW^a, \\
(3.23) & \quad \lim_{N \to \infty} N^{-1/3} H(X^{k; \mu_l}) = \frac{L_0^a(R^{\mu_l})}{2}, \\
(3.24) & \quad \lim_{N \to \infty} \sum_{a \in N^{1/3}N} L^a(X^{k; \mu_l}) \frac{a_{[N^{1/3}a]}}{N^{1/6}} = s a \int_0^\infty L^a_T(R^{\mu_l}) \, dW^a.
\end{align*}
\]

**Proof.** The lemma can be obtained from the coupling construction of Theorem 2.3 by the same arguments as in the derivation of [13 Proposition 4.9] from the coupling in [13 Proposition 4.1]. More specifically, one starts with the case \( n = 1 \) and \( \mu_1 = \delta_x \) for some \( x \geq 0 \). Then, the joint convergences (3.21)-(3.24) in distribution are due to the convergence of the associated joint characteristic functions, which under the coupling of Theorem 2.1 is a consequence of the almost sure convergences of the conditional characteristic functions

\[
\begin{align*}
(3.25) & \quad \lim_{N \to \infty} E_{\xi} \left[ \exp \left( i \theta \sum_{a \in N^{1/3}(n-1/2)} L^a(X^{k; x}) \frac{\xi_{[N^{1/3}a]}}{N^{1/6}} \right) \right] \\
& \quad = E_{W^\xi} \left[ \exp \left( i \theta s \int_0^\infty L^a_T(R^x) \, dW^a \right) \right], \\
& \quad \lim_{N \to \infty} E_a \left[ \exp \left( i \theta \sum_{a \in N^{1/3}N} L^a(X^{k; x}) \frac{a_{[N^{1/3}a]}}{N^{1/6}} \right) \right] \\
& \quad = E_{W^a} \left[ \exp \left( i \theta s a \int_0^\infty L^a_T(R^x) \, dW^a \right) \right]
\end{align*}
\]

for all \( \theta \in \mathbb{R} \) (see [13] first half of p. 18 for more details). The latter follow from the central limit theorem in the form of the upper bound in [3] Theorem 8.4], the coupling of Theorem 2.1 and Assumption 1.2 (see [13] pp. 18–19 for more details).

In the case of \( n = 1 \) and a general probability measure \( \mu_1 \), the joint convergences (3.21)-(3.24) in distribution can be deduced from the previous case by integrating with respect to \( \mu_1 \) and relying on the uniform boundedness of characteristic functions. Finally, in the case of \( n > 1 \), one can repeat the same proof, but invoking the multidimensional version of the central limit theorem used before, obtaining this way also the convergences of (3.20) in the sense of convergence of finite-dimensional distributions. The latter can be improved to the desired distributional convergences.
of processes by applying a standard tightness result (see e.g. [1] Problem 8.4 and proof of Theorem 8.1). \qed

We also prepare the following lemma needed in our proof of Proposition 3.3.

Lemma 3.5. Let \( \mu \) be a probability measure on \([0, \infty)\). Then, for each \( j = 0, 1, \ldots, \) under any coupling such that \( \lim_{N \to \infty} N^{-1/3} X^k_{T_k-j} = R^\mu_T \) almost surely, it holds

\[
\lim_{N \to \infty} N^{1/3} \int_{N^{-1/3} X^k_{T_k-j}}^{N^{-1/3}(X^k_{T_k-j}+1)} g(y) \, dy = g(R^\mu_T)
\]

with probability one, for any uniformly continuous function \( g : [0, \infty) \to \mathbb{R} \).

Proof. It suffices to write

\[
N^{1/3} \int_{N^{-1/3} X^k_{T_k-j}}^{N^{-1/3}(X^k_{T_k-j}+1)} g(y) \, dy
\]

\[
= N^{1/3} \int_{N^{-1/3} X^k_{T_k-j}}^{N^{-1/3}(X^k_{T_k-j}+1)} g(y) - g(N^{-1/3} X^k_{T_k-j}) \, dy + g(N^{-1/3} X^k_{T_k-j})
\]

and to note that the integral on the right-hand side tends to 0 with probability one, as \( N \to \infty \), by the uniform continuity of \( g \), whereas \( \lim_{N \to \infty} g(N^{-1/3} X^k_{T_k-j}) = g(R^\mu_T) \) almost surely. \qed

We are now ready to prove Proposition 3.3.

Proof of Proposition 3.3. Let us first consider fixed \( j, T, f \) and \( g \). Since the terms \( \widetilde{S} X^j(f_k, g_k; \mathcal{S}, \mathcal{S}) \) are bounded uniformly in \( N \), it suffices to show the convergence of moments. Further, without loss of generality we may assume \( f_k \geq 0 \) and \( \int_0^\infty f_k(x) \, dx = 1 \) (otherwise we write \( f_k \) as the difference of its positive and negative parts, and the latter as multiples of functions of the described kind). In particular, this allows to define \( \mu \) as the probability measure with the density \( f_K \).

With i.i.d. copies \( X^k_{-j;\mu_1}, X^k_{-j;\mu_2}, \ldots, X^k_{-j;\mu_n} \) of \( X^k_{-j;\mu} \) and i.i.d. copies \( R^\mu_1, R^{\mu_2}, \ldots, R^{\mu_n} \) of \( R^\mu \), the \( n \)-th moment of \( \widetilde{S} X^j(f_k, g_k; \mathcal{S}, \mathcal{S}) \) can be expressed using Fubini’s theorem as

\[
\mathbb{E} \left[ \prod_{l=1}^n \left( \tilde{F}_j^{(\mathcal{S})} \left( X^k_{-j;\mu_l}, a, \xi \right) \cdot N^{1/3} \int_{N^{-1/3} X^k_{T_k-j} \xi}^{N^{-1/3}(X^k_{T_k-j}+1)} g_K(y) \, dy \right) \right],
\]

whereas the \( n \)-th moment of \( \int_0^\infty f_k(x) \left( U_{f_k(x)}^{(\mathcal{S})} g_K(x) \right) \, dx \) reads

\[
\mathbb{E} \left[ \prod_{l=1}^n \left( \mathcal{S} \vee \exp \left( - \int_0^T \frac{R_{\mu_l}}{2} \, dt + s_\xi \int_0^\infty L^e_T(R_{\mu_l}) \, dW_0^\xi - \frac{L^0_T(R_{\mu_l})}{2} \right) \right) \right].
\]

To establish the convergence of the expectation in (3.29) to that in (3.30) we work under the coupling of Lemma 3.3 and view the random walks \( X^k_{-j;\mu_1}, X^k_{-j;\mu_2}, \ldots, X^k_{-j;\mu_n} \) as the respective restrictions of \( X^k;\mu_1, X^k;\mu_2, \ldots, X^k;\mu_n \) to \([0, T_k-j]\). Then,
\( X^{k-j; \mu_1}, X^{k-j; \mu_2}, \ldots, X^{k-j; \mu_n} \) inherit the asymptotics of \((3.21)-(3.24)\) from \( X^{k; \mu_1}, X^{k; \mu_2}, \ldots, X^{k; \mu_n} \), and Lemma 3.3 applies, so that

\[
\lim_{N \to \infty} N^{1/3} \int_{N^{-1/3} X_{Tk-j}^{k-j; \mu_1}}^{N^{-1/3} (X_{Tk-j}^{k-j; \mu_1} + 1)} g_k(y) \, dy = g_k(R_T^{\mu_l}), \quad l = 1, 2, \ldots, n
\]

with probability one.

We proceed to the asymptotics of \( \tilde{F}_j^{(S, Z)}(X^{k-j; \mu_1}, a, \xi) \), \( l = 1, 2, \ldots, n \). Our first claim is that

\[
\lim_{N \to \infty} \prod_{i=1}^{k-j-H(X^{k-j; \mu_1})} \frac{\sqrt{N - X_{N-2/3(1-i)}^{k-j; \mu_1} \wedge X_{N-2/3(1-i)}^{k-j; \mu_1}}}{\sqrt{N}} = \exp \left( - \int_0^T \frac{R_T^{\mu_1}}{2} \, dt \right)
\]

for \( l = 1, 2, \ldots, n \) almost surely. Indeed, for every such \( l \), according to the Taylor expansion \( \log(1+z) = z + O(z^2) \) about \( z = 0 \), an approximation as in the third line of \((3.9)\) (with \( X^{k-j; x}, \hat{X}^{k-j; x} \) replaced by \( X^{k-j; \mu_1}, \hat{X}^{k-j; \mu_1} \)) holds up to a multiplicative error of at most

\[
\exp \left( O \left( N^{-4/3} \sup_{t \in [0,T_{k-j}]} X_t^{k-j; \mu_1} \right)^2 \right).
\]

Writing the resulting approximation in terms of \( X^{k-j; \mu_1} \) we obtain \((3.32)\) as an elementary consequence of \((3.21)\).

Next, we prove the joint convergence in distribution

\[
\lim_{N \to \infty} \frac{\hat{X}_{N-2/3(1-i)}^{k-j; \mu_1} \wedge \hat{X}_{N-2/3(1-i)}^{k-j; \mu_1}}{\sqrt{N}} = \exp \left( s_\xi \int_0^\infty L_t^2(R_t^{\mu_1}) \, dW_t^\xi \right)
\]

for \( l = 1, 2, \ldots, n \). To this end, we use the Taylor expansion \((1 - z)^{-1/2} = 1 + O(z)\) about \( z = 0 \) to conclude that, for each \( l \), an approximation as in the third line of \((3.10)\) (with \( X^{k-j; \mu_1}, \hat{X}^{k-j; \mu_1} \) in place of \( X^{k-j; x}, \hat{X}^{k-j; x} \)) applies up to a modification of each

\[
\frac{\hat{X}_{N-2/3(1-i)}^{k-j; \mu_1} \wedge \hat{X}_{N-2/3(1-i)}^{k-j; \mu_1}}{\sqrt{N}} \to \frac{\xi \hat{X}_{N-2/3(1-i)}^{k-j; \mu_1} \wedge \hat{X}_{N-2/3(1-i)}^{k-j; \mu_1}}{\sqrt{N}} \left( 1 + O \left( N^{-1} \sup_{t \in [0,T_{k-j}]} X_t^{k-j; \mu_1} \right) \right).
\]

At this point, we employ the Taylor expansion \( \log(1+z) = z + O(z^2) \) about \( z = 0 \) to obtain an expression as in the fourth line of \((3.10)\), with the summands therein modified to

\[
\frac{\xi \hat{X}_{N-2/3(1-i)}^{k-j; \mu_1} \wedge \hat{X}_{N-2/3(1-i)}^{k-j; \mu_1}}{\sqrt{N}} \left( 1 + O \left( N^{-1} \sup_{t \in [0,T_{k-j}]} X_t^{k-j; \mu_1} \right) \right)
\]

\[
+ O \left( \frac{\xi \hat{X}_{N-2/3(1-i)}^{k-j; \mu_1} \wedge \hat{X}_{N-2/3(1-i)}^{k-j; \mu_1}}{\sqrt{N}} \right)^2 \left( 1 + O \left( N^{-1} \sup_{t \in [0,T_{k-j}]} X_t^{k-j; \mu_1} \right) \right)^2).
\]

The contribution of the first line in \((3.36)\) can be evaluated as in the equality on the fifth line of \((3.10)\), which leads to the limit in distribution of \((3.22)\) after recalling
The contribution of the second line in (3.36) is asymptotically negligible due to the almost sure convergence
\[ \lim_{N \to \infty} \sum_{i=1}^{k-j} \frac{\left( \mathcal{X}^{k-j;\mu_1}_{N-2/3(i-1)} \right)^2}{N} = 0 \] (3.37)
(simply apply the Borel-Cantelli lemma upon bounding the fourth moment of the latter sum via Assumption (1.2(e)) and (3.21). All in all, we arrive at (3.34).

Putting (3.32) and (3.34) together with the almost sure convergences
\[ \ell_{N}^{H(X^{k-j;\mu_1})} = \left(1 - \frac{N^{1/3}(1 - \ell_{N})}{N^{1/3}} \right) \rightarrow \exp \left( -w \frac{\int_0^\infty L_0^a(R^a)}{2} \right) \] (3.38)
for \( l = 1, 2, \ldots, n \) (see (3.28)), the convergences in distribution
\[ \lim_{N \to \infty} \frac{1}{j!} \left( \sum_{i=0}^{\kappa-j-H(X^{k-j;\mu_1})} a_{k-j;\mu_1}^{k-j;\mu_1}_{N-2/3i} \right)^j = \frac{1}{j!} \left( \frac{8a}{2} \int_0^\infty L_0^a(R^a) dW_a \right)^j \] (3.39)
for \( l = 1, 2, \ldots, n \) (see (3.28)) and (3.31) we conclude that the expectation in (3.28) converges to that in (3.30). Moreover, the joint convergence for any finitely many \( j \)'s, \( T \)'s, \( f \)'s and \( g \)'s can be shown by the same arguments, the only difference being that the formulas for moments in (3.29) and (3.30) have to be replaced by the corresponding formulas for joint moments.

3.3. Uniform moment bounds. In this subsection, we establish some uniform moment estimates, which will allow us to lift the truncations and the continuity assumption on the \( g \)'s of Proposition 3.3. To this end, we define the functionals
\[ \tilde{F}_j(X^{k-j;x}, a, \xi) = \prod_{i=1}^{k-j-H(X^{k-j;x})} \sqrt{N - X^{k-j;1}_{N-2/3(i-1)}} \] (3.40)
and, with any \( f, g \in D \) and random variable \( Z_N \) (possibly depending on \( X^{k-j;x} \), the \( a_m \)'s and the \( \xi_m \)'s), set
\[ \tilde{S}_{k}^j(f, g; Z_N) \] (3.41)
\[ := \int_0^{N^{2/3}} f(x) E_{X^{k-j;x}} \left[ \tilde{F}_j(X^{k-j;x}, a, \xi) \cdot N^{1/3} \int_{N^{1/3}X^{k-j;x}_{k-j}} g(y) dy \cdot Z_N \right] dx \]
for \( j = 0, 1, \ldots \). We also let
\[ \overline{S}_{k}^j(f, g; K; Z_N) := \tilde{S}_{k}^j(f, g; Z_N) - \tilde{S}_{k}^j(f_k, g_k; Z_N), \quad j = 0, 1, \ldots \] (3.42)
Proposition 3.6. For all $f, g \in \mathcal{D}$, one can find $N_0 \in \mathbb{N}$ and $C(K, n) < \infty$ with
\[ \lim_{K \to \infty} C(K, n) = 0 \quad \text{such that, for all } N \geq N_0, \text{ if } Z_N \text{ satisfies} \]
\[ (3.43) \quad \mathbb{E}[|Z_N|^{3n}] \leq \Theta(3n), \]
one has
\[ (3.44) \quad \mathbb{E}\left[\left|\overline{S}_k^n(f, g; K; Z_N)\right|^n\right] \leq \frac{C(K, n) \Theta(3n)^{1/3}}{(3/2)^n}, \quad K \in \mathbb{N} \cup \{0\}, \quad j = 0, 1, \ldots. \]

The proof of Proposition 3.6 relies on the following lemma.

Lemma 3.7. For all $1 \leq p < 3$ and $\theta \geq 0$, there exist constants $C = C(p, \theta) < \infty$, $c = c(\theta) > 0$ and $N_0 \in \mathbb{N}$ such that
\[ (3.45) \quad \sup_{N \geq N_0} \mathbb{E}\left[\exp\left(-\theta N^{-2/3} \sum_{i=1}^{k} N^{-1/3} X_{k-2/3_i}^x\right)\right] \leq Ce^{-cx}, \quad x > 0, \]
\[ (3.46) \quad \sup_{N \geq N_0} \mathbb{E}\left[\exp\left(\theta N^{-1/3} \sum_{a \in N^{-1/3(3n)}} L^a(X^k)^p\right)\right] \leq C, \quad x > 0, \]
\[ (3.47) \quad \sup_{N \geq N_0} \mathbb{E}\left[\exp\left(\theta N^{-1/3} \sum_{a \in N^{-1/3(3n-1/2)}} L^a(X^k)^p\right)\right] \leq C, \quad x > 0, \]
\[ (3.48) \quad \sup_{N \geq N_0} \mathbb{E}\left[\ell^H_N(X^{x_k})\right] \leq C, \quad x > 0. \]

Proof. Recall the random walks $\overline{v}$ and $v(\overline{v})$ introduced in (2.18) and the sentence following it. Throughout this proof, we condition on $\overline{Y}_0 = [N^{1/3}]$ and assume that $\overline{Y}$ and $X^{k,x}$ are coupled as in Remark 2.3. We further write
\[ (3.49) \quad \rho_k = \max_{0 \leq i \leq k} v(\overline{v})_i - \min_{0 \leq i \leq k} v(\overline{v})_i \]
for the range of the SSRW $v(\overline{v})$ after $k$ steps. It is clear that, for $i = 0, 1, \ldots, k$,
\[ (3.50) \quad -X_{k-2/3_i}^x \leq -\min_{0 \leq i \leq k} v(\overline{v})_i \leq -\min_{0 \leq i \leq k} v(\overline{v})_i \leq -[N^{1/3}] + \rho_k. \]

According to [8 inequality (6.2.3)] (the case $p = 1$ therein), one has
\[ (3.51) \quad \mathbb{E}\left[(N^{-1/3} \rho_k)^n\right] \leq \sqrt{n!} (CT^{1/n})^n, \quad n \in \mathbb{N} \]
with some uniform constant $C < \infty$. Thus, the exponential moment of $N^{-1/3} \rho_k$ can be bounded by a constant independent of $N$ and $x$, yielding (3.45).

In view of (2.23),
\[ (3.52) \quad L^a(X^{k,x})^p \leq 2^{p-1}\left(L^a_{N^{-2/3}; T}(v(\overline{v}))^p + L^a_{N^{-2/3}; T}(v(\overline{v}))^p\right). \]

Hence, it suffices to show (3.46) with $\theta$ replaced by $2^{p-1} \theta$ and $\sum_{a \in N^{-1/3}} L^a(X^{k,x})^p$ by $\sum_{a \in N^{-1/3}} L^a_{N^{-2/3}; T}(v(\overline{v}))^p$. Repeating the proof of [13 Proposition 4.3] verbatim we find a constant $C = C(p) < \infty$ such that
\[ (3.53) \quad N^{-1/3} \sum_{a \in N^{-1/3}} L^a_{N^{-2/3}; T}(v(\overline{v}))^p \leq C\left((N^{-1/3} \rho_k)^{p-1} + N^{-(p-1)/3}\right) \]
(note that even though [13] considers SSRW bridges, all the combinatorial identities therein apply to SSRWs as well). At this point, (3.46) follows from (3.51). Moreover, (3.47) is a consequence of (3.46).

\[ L^a(X^{k:x}) \leq 2L^{a+N^{-1/3}/2}(X^{k:x}), \quad a \in N^{-1/3}(N - 1/2) \]
and (3.46).

From Proposition 2.3 we know that \( H(X^{x:k}) = \sup_{t \in [0,T_k]}(-\widetilde{X}^k_{t,x})^+ \) under an appropriate coupling. In particular, \( H(X^{x:k}) \) is stochastically dominated by \( \rho_k \). Consequently, for \( N \in \mathbb{N} \) large enough, the random variable inside the expectation in (3.48) is stochastically dominated by \( \rho_k \).

\[ \ell_N^{\rho_k} = \left(1 - \frac{N^{1/3}(1 - \ell_N)}{N^{1/3}}\right)^{N^{1/3}/(\theta N^{-1/3})} \approx e^{-(w + o(1)) - (\theta N^{-1/3})}, \]
where \( o(1) \) is non-random, so that (3.48) also follows from (3.51).

**Proof of Proposition 3.6.** After observing

\[ \mathbb{S}_{\xi}(f, g; K; Z_N) = \int_0^{N^{2/3}} \int_0^{N^{2/3}} N^{1/3} f(x) \cdot \frac{Q^{x,y}}{2^{k-j}} \mathbb{E}_{X^{k-j:x}} \left[ \mathbb{F}_j(X^{k-j:x}, a, \xi) \cdot Z_N \mid X^{k-j:x}_{T_{k-j}} = [N^{1/3}y] \right] g(y) \, dx \, dy - \int_0^{N^{2/3}} \int_0^{N^{2/3}} N^{1/3} f(x) h_K(x) \, dx \, dy \]
we estimate \( \mathbb{S}_{\xi}(f, g; K; Z_N) \) by moving the absolute value inside the double integral and using

\[ 0 \leq 1 - h_K(x) h_K(y) \leq 1_{(K, \infty)}(x) + 1_{(K, \infty)}(y), \quad x, y \geq 0. \]

Since the roles of the variables \( x \) and \( y \) are symmetric, we only focus on the term in \( \mathbb{E}[\mathbb{S}_{\xi}(f, g; K; Z_N)] \) originating from \( 1_{(K, \infty)}(x) \). We bound the latter by inserting an absolute value into the conditional expectation, applying Fubini’s theorem and letting \( f_K := f 1_{[K, \infty)} \), thereby obtaining

\[ \int_{[0, N^{2/3})^n} \mathbb{E} \left[ \prod_{l=1}^{n} f_K(x_l) \mathbb{E}_{X^{k-j:x_l}} \left[ \mathbb{F}_j(X^{k-j;x_l}, a, \xi) \right] \right. \cdot N^{1/3} \int_{N^{-1/3}X^{k-j:x_l+1}_{T_{k-j}}} N^{-1/3} \frac{Q^{x,y}}{2^{k-j}} \mathbb{E}_{X^{k-j:x_l}} \left[ \mathbb{F}_j(X^{k-j:x_l}, a, \xi) \right] g(y) \, dy \mid Z_N \left. \right] \right] \, dx_1 \, dx_2 \ldots \, dx_n. \]
A repeated application of Hölder’s and Jensen’s inequalities shows further that the quantity in (3.58) is at most

\[
\left( \int_0^{N^{2/3}} |\tilde f_K(x)| E[|Z_N|^{3n}]^{1/(3n)} E\left[ \left( N^{1/3} \int_0^{N^{-1/3}(X^k_{T_n,j} + 1)} |g(y)| \, dy \right)^{3n} \right]^{1/(3n)} \right)^n.
\]

Due to \( f \in D \) and (3.43), we have

\[
\left| \tilde f_K(x) \right| E[|Z_N|^{3n}]^{1/(3n)} \leq C_1 e^{C_2 x^{1-\delta}} 1_{(K, \infty)}(x) \Theta(3n)^{1/(3n)}.
\]

In view of \( g \in D \), we can choose \( C_1, C_2 \) and \( \delta \) such that also

\[
N^{1/3} \int_0^{N^{-1/3}(X^k_{T_n,j} + 1)} |g(y)| \, dy \leq C_1 \exp \left( C_2 (N^{-1/3} X^k_{T_n,j})^{1-\delta} \right).
\]

Moreover, by the argument leading to (3.50) and with the same notation as there,

\[
N^{-1/3} X^k_{T_n,j} \leq x + N^{-1/3} \rho_k.
\]

It then follows from (3.51) that, with some \( \bar C_1 = \bar C_1(C_1, n) < \infty \),

\[
E\left[ \left( N^{1/3} \int_0^{N^{-1/3}(X^k_{T_n,j} + 1)} |g(y)| \, dy \right)^{3n} \right]^{1/(3n)} \leq \bar C_1 e^{C_2 x^{1-\delta}}.
\]

It remains to control \( E[|\tilde f_j(X^k_{T_n,j}, a, \xi)|^{3n}]^{1/(3n)} \). For this purpose, we fix an \( \varepsilon \in (0, \delta/3) \) and distinguish the cases \( x \in (0, N^{2/3-\varepsilon}] \) and \( x \in (N^{2/3-\varepsilon}, N^{2/3}] \). In the first case, we use Hölder’s inequality to estimate \( E[|\tilde f_j(X^k_{T_n,j}, a, \xi)|^{3n}]^{1/(3n)} \) by the product of the four terms

\[
\text{(3.64)} \quad E\left[ \left( \prod_{i=1}^{k-j-H(X^k_{T_n,j})} \frac{1}{\sqrt{N}} \right)^{12n} \right]^{1/(12n)},
\]

\[
\text{(3.65)} \quad E\left[ \left( \prod_{i=1}^{k-j-H(X^k_{T_n,j})} \frac{\xi_r^{k-j,x} R_{N^{-2/3}(i-1)} \wedge \tilde X^k_{N^{-2/3}}} {\sqrt{N}} \right)^{12n} \right]^{1/(12n)},
\]

\[
\text{(3.66)} \quad E\left[ \xi_{N^{12n} H(X^k_{T_n,j})} \right]^{1/(12n)},
\]

\[
\text{(3.67)} \quad E\left[ \left( \frac{1}{j! (2\sqrt{N})^j} \sum_{i=0}^{k-j-H(X^k_{T_n,j})} a_{k-j-H(X^k_{T_n,j})} \right)^{12n} \right]^{1/(12n)}.
\]

Thanks to \( \frac{1}{\sqrt{N}} \leq e^{-z/(2N)} \), \( z \in [0, N] \) and (3.45), the quantity in (3.64) is not greater than \( C e^{-cz} + O(J N^{-1}) \). Turning to the term in (3.65), we write the expectation with respect to the \( \xi_{n_i} \)'s as a product and note that, due to Assumption (2.2)\(c\),
inequality (4.21)] yields for each factor a bound of the form
(3.68)
\[
\exp \left( \frac{12nL^a(X^{k-j:x})}{N^{-1/3} \sqrt{N-a}} \right) + C' \left( \frac{(12nL^a(X^{k-j:x}))^2}{N^{-2/3}(N-a)} + \frac{(12nL^a(X^{k-j:x}))^{\gamma'}}{N^{-\gamma'/3}(N-a)^{\gamma'/2}} \right),
\]
with some $C' < \infty$ and $2 < \gamma' < 3$. For $N \in \mathbb{N}$ large enough, $N - a \geq N/2$ when $L^a(X^{k-j:x}) \neq 0$, which with Assumption \[ 1.2 \](a) leads to the expectation of
(3.69)
\[
\exp \left( C \sum_{a \in N^{-1/3}(N-1/2)} \frac{12nL^a(X^{k-j:x})}{N^{1/2}} + \frac{(12nL^a(X^{k-j:x}))^2}{N^{1/3}} + \frac{(12nL^a(X^{k-j:x}))^{\gamma'}}{N^{\gamma'/6}} \right),
\]
as an estimate on the expectation in (3.66). In addition, (3.48) reveals that the expression in (3.66) is at most $Ce^{O(jN^{-1/3})}$. Finally, the expectation with respect to the $a_m$’s in (3.67) can be controlled via a combination of $|e^x| \leq e^x + e^{-x}$, $z \in \mathbb{R}$, inequality (4.20) and Assumption \[ 1.2 \](a) by
(3.70)
\[
\frac{C}{2^{12n}} \exp \left( C \sum_{a \in N^{-1/3}(N-1/2)} \frac{12nL^a(X^{k-j:x})}{N^{1/2}} + \frac{(12nL^a(X^{k-j:x}))^2}{N^{1/3}} + \frac{(12nL^a(X^{k-j:x}))^{\gamma'}}{N^{\gamma'/6}} \right),
\]
with the same $2 < \gamma' < 3$ as before. Putting everything together, applying Hölder’s inequality, and appealing to (3.47), (3.40) we arrive at
(3.71)
\[
E \left[ \left| F_j(X^{k-j:x}, a, \xi) \right|^{3n} \right]^{1/(3n)} \leq \frac{Ce^{-cx+O(jN^{-\gamma'})}}{2^j}, \quad x \in \left( 0, N^{2/3-\varepsilon} \right].
\]

In the case $x \in \left( N^{2/3-\varepsilon}, N^{2/3} \right]$, for all $N \in \mathbb{N}$ large enough, $X^{k-j:x} \geq N^{1-\varepsilon}/2$, $t \in [0, T_{k-j}]$, so that
(3.72)
\[
\Pi_{i=1}^{k-j} \left| \sqrt{N - X_{N-2/3(i-1)}^{k-j:x}} + \xi_{X_{N-2/3(i-1)}^{k-j:x}}^{k-j:x} \right| \leq \prod_{i=1}^{k-j} \left( \sqrt{N - N^{-1-\varepsilon}/2 + \frac{X_{N-2/3(i-1)}^{k-j:x}}{N}} \right) \leq e^{-kN^{-\varepsilon}/4+O(jN^{-\varepsilon})} \cdot \exp \left( 2 \sum_{a \in N^{-1/3}(N-1/2)} L^a(X^{k-j:x}) \left| \xi_{X_{N-2/3(i-1)}^{k-j:x}} \right| N^{1/6} \right) - \frac{\varepsilon}{2^j}.
\]
Using Hölder’s inequality and Lemma 3.7 as above, but changing the $a_m$’s and $\xi_m$’s to their absolute values and Assumption \[ 1.2 \](a) to Assumption \[ 1.2 \](c), we get
(3.73)
\[
E \left[ \left| F_j(X^{k-j:x}, a, \xi) \right|^{3n} \right]^{1/(3n)} \leq \frac{Ce^{-kN^{-\varepsilon}/4+O(jN^{-\varepsilon})+CN^{1/6}}}{2^j}, \quad x \in \left( N^{2/3-\varepsilon}, N^{2/3} \right].
\]
Lastly, we insert the right-hand sides of (3.60), (3.63), (3.71), (3.73) into (3.59):

\[
\frac{C e^{O(jnN^{-\varepsilon})} \Theta(3n) 1/3}{2^n} \left( \int_{K}^{\infty} e^{C x^{1-\delta - \varepsilon}} \, dx + e^{-kN^{-\varepsilon}/4+C N^{1/6}} \int_{N^{2/3-\varepsilon}K}^{\infty} e^{C x^{1-\delta}} \, dx \right)^n.
\]

(3.74)

The estimate (3.44) readily follows upon recalling \( k = \lceil TN^{2/3} \rceil \) and \( \varepsilon \in (0, \delta/3) \). \( \square \)

3.4. Proof of Theorem 1.7. In order to establish Theorem 1.7, we first argue that Proposition 3.3 remains true when \( S = -\infty \) and \( \overline{S} = \infty \). Indeed, the convergence in distribution of the random variable inside the expectation of (3.29) to that inside the expectation of (3.30) continues to hold. This yields the convergence (3.19) with \( S = -\infty \) and \( \overline{S} = \infty \) in the sense of moments, since the random variable of (3.29) is uniformly integrable, as \( N \in \mathbb{N} \) varies, by (3.44) with \( K = 0 \) and \( Z_N = 1 \). The same argument gives also the joint convergence in the sense of moments. The convergence (3.19) with \( S = -\infty \) and \( \overline{S} = \infty \) in distribution results from an identification of the limit points in distribution with the limit in the sense of moments via the stochastic domination argument in [13, proof of Lemma 4.15]. Such identification in the case of the joint convergence in distribution is most easily seen after an application of the Skorokhod representation theorem, leading to two random vectors with componentwise inequalities between them and same joint moments.

Next, we prove Theorem 1.7 under the additional assumption that the \( g \)'s therein are continuous. Let

\[
\Delta^j_k(f, g) := \mathcal{S}^j_k(f, g) - \tilde{\mathcal{S}}^j_k(f, g; 1), \quad N \in \mathbb{N}, \quad j = 0, 1, \ldots
\]

(3.75)

In view of (3.7), for all \( K \in \mathbb{N} \), one has

\[
(\pi_N f)^\top \mathcal{M}_{T;N}^{\beta;w}(\pi_N g) = \sum_{j=0}^{k} \tilde{\mathcal{S}}^j_k(f, g; 1) + \sum_{j=0}^{k} \mathcal{S}^j_k(f, g, K; 1) + \sum_{j=0}^{k} \Delta^j_k(f, g).
\]

(3.76)

We aim to take the \( N \to \infty \) limit of the right-hand side in (3.76) and start with the asymptotics of the first sum therein. For every finite set of summands \( \mathcal{S}^j_k(f, g; 1) \), \( \mathcal{S}^j_k(f, g, K; 1) \), \ldots, \( \tilde{\mathcal{S}}^j_k(f, g; 1) \), their joint limit in distribution and in the sense of moments is determined by the right-hand side of (3.19) with \( S = -\infty \) and \( \overline{S} = \infty \). This and the moment bounds of (3.44) imply that the first sum on the right-hand side of (3.76) converges to \( \int_0^{\infty} f(x) (\mathcal{U}^{\beta;w}_T g_K)(x) \, dx \) in distribution and in the sense of moments. Since the moment bounds of (3.44) for \( \mathcal{S}^j_k(f, g; 0; 1) \) are inherited by their \( N \to \infty \) limits, we have, in addition,

\[
\lim_{K \to \infty} \lim_{N \to \infty} \sum_{j=0}^{k} \tilde{\mathcal{S}}^j_k(f, g; 1) = \lim_{K \to \infty} \int_0^{\infty} f_K(x) (\mathcal{U}^{\beta;w}_T g_K)(x) \, dx
\]

(3.77)

\[
= \int_0^{\infty} f(x) (\mathcal{U}^{\beta;w}_T g)(x) \, dx
\]

in distribution and in the sense of moments.
Moreover, the moment bounds of (3.44) reveal that

\[
\lim_\mathcal{K} \lim_{N \to \infty} \sum_{j=0}^k \mathcal{S}_k^j(f, g; 1) = 0
\]

in \(L^n\), for all \(n \in \mathbb{N}\). To analyze the third sum on the right-hand side of (3.76), we introduce, for all \(j = 1, 2, \ldots\), the notations

\[
(3.79) \quad h_j(N) = \sum_{0 \leq \iota_1 \leq \cdots \leq \iota_j \leq k} \prod_{j'=1}^j a_{k-j' N^{-2/3}}^{j'}, \quad p_j(N) = \sum_{i=0}^{k-j-H(X_{k-j'^{2/3}})} (a_{k-j'^{2/3}}^{j'})^i,
\]

and \([z^j]P(z)\) for the coefficient of \(z^j\) in a power series \(P(z)\). Then, the Newton identities relating the complete homogeneous symmetric functions to the power sums (see e.g. [20, Chapter 1, Section 2]) yield

\[
(3.80) \quad \frac{h_j(N)}{(2\sqrt{N})^j} = \frac{p_1(N)^j}{j! (2\sqrt{N})^j} + \sum_{i=0}^{j-1} \left( \frac{p_i(N)^j}{i! (2\sqrt{N})^i} \right) \left( [z^{j-i}] \exp \left( \sum_{j'=2}^{\infty} \frac{p_{j'}(N)}{(2\sqrt{N})^{j'}} z^{j'} \right) \right).
\]

Therefore, with

\[
(3.81) \quad Z_N^{j,i} := [z^{j-i}] \exp \left( \sum_{j'=2}^{\infty} \frac{p_{j'}(N)}{(2\sqrt{N})^{j'}} z^{j'} \right), \quad \iota = 0, 1, \ldots, j-1,
\]

it holds

\[
(3.82) \quad \sum_{j=0}^k \Delta_k^j(f, g) = \sum_{j=0}^k \sum_{i=0}^{j-1} \mathcal{S}_k^j(f, g; Z_N^{j,i}).
\]

By [13, Lemma 4.20], one can find bounds \(E[|Z_N^{j,i}|^n] \leq \Theta(3n, j-i, N)\) such that

\[
(3.83) \quad \lim_{N \to \infty} \sum_{j=0}^k \sum_{i=0}^{j-1} \Theta(3n, j-i, N)^{1/(3n)} (3/2)^i = 0.
\]

A combination of the triangle inequality for the \(L^n\) norm, the moment bounds of (3.44) and the property (3.83) gives

\[
(3.84) \quad \lim_{N \to \infty} \sum_{j=0}^k \Delta_k^j(f, g) = 0
\]

in \(L^n\), for all \(n \in \mathbb{N}\). This finishes the proof of Theorem 1.7 under the continuity assumption on the \(g\)'s.

For general \(f, g \in \mathcal{D}\), the same arguments as above reveal that it suffices to identify, for all \(K \in \mathbb{N}\), the limit of \(\sum_{j=0}^k \mathcal{S}_k^j(f_K, g_K; 1)\) in distribution and in the sense of moments as \(\int_0^\infty f_K(x) \left( \mathcal{U}_T^{j,w} g_K \right)(x) \, dx\). In fact, it is enough to establish

\[
(3.85) \quad \lim_{N \to \infty} \sum_{j=0}^k \mathcal{S}_k^j(f_K, g_K; 1) = \int_0^\infty f_K(x) \left( \mathcal{U}_T^{j,w} g_K \right)(x) \, dx
\]
in distribution, since the moment bounds of (3.44) for \( \tilde{\mathcal{S}} \) imply the convergence of moments. To see (3.85) we pick \( g_{\eta,N} \), \( \eta \in \mathbb{N} \) in \( C([0,\infty)) \) so that
\[
(3.86) \quad v_{\eta} := \|g_{\eta,K}h_K - g_K\|_{L^2([0,\infty))} \to 0.
\]

Recalling the symmetry of \( \tilde{\mathcal{S}} \) (cf. (3.56)), applying the Cauchy-Schwarz inequality, and repeating the proof of Proposition 3.6 mutatis mutandis we get
\[
(3.87) \quad \mathbb{E} \left[ \left| \tilde{\mathcal{S}}_k^j(f, gK; 1) - \tilde{\mathcal{S}}_k^j(f, g_{\eta,K}h_K; 1) \right|^2 \right] \leq v_{\eta}^2 \mathbb{E} \left[ \int_0^{N^{3/2}} E_{X^{k-j},x} \left[ f_j(X^{k-j}, a, \xi) \cdot N^{1/3} \int_{N^{-1/3}X^{k-j}} f_k(y) \, dy \right]^2 \, dx \right] \leq v_{\eta}^2 Ce^{O(N^{-r})}.
\]

To complete the proof of Theorem 1.4 we observe that
\[
(3.88) \quad \forall \eta \in \mathbb{N} : \lim_{N \to \infty} \sum_{j=0}^k \tilde{\mathcal{S}}_k^j(f, g_{\eta,K}h_K; 1) = \int_0^\infty f_K(x) \left( \mathcal{U}_T^w(g_{\eta,K}h_K) \right)(x) \, dx
\]
in distribution and that
\[
(3.89) \quad \lim_{\eta \to \infty} \int_0^\infty f_K(x) \left( \mathcal{U}_T^w(g_{\eta,K}h_K) \right)(x) \, dx = \int_0^\infty f_K(x) \left( \mathcal{U}_T^w g_K \right)(x) \, dx
\]
almost surely, thanks to Proposition 1.8(c).

4. Properties of the limiting operators

The goal of this section is to prove Proposition 1.8. We start by preparing some auxiliary constructions and results. From this point on, the entries of \( M_N^{\beta,w} \) are specified as in Remark 1.3. We also let
\[
(4.1) \quad A_N^{\beta,w} := N^{1/6} (2\sqrt{N} - M_N^{\beta,w}),
\]
viewed as an operator acting on \( L^2([0,\infty)) \) via Remark 1.3. The next proposition is a direct corollary of [6] Proposition 2.8, Remark 2.9, Lemma 2.7, Theorem 2.10 and its proof (note that [6] Assumptions 1-3 for our particular model can be verified as in [6] Section 3, last paragraph).

**Proposition 4.1.** For all \( \beta > 0 \) and \( w \in \mathbb{R} \), the operator \( \mathcal{H}^{\beta,w} \) of (1.8) almost surely possesses a purely discrete spectrum \( \Lambda_1 < \Lambda_2 < \cdots \) satisfying \( \Lambda_q \to \infty \) as \( q \to \infty \). The corresponding eigenspaces are one-dimensional, and each is therefore spanned by a normalized eigenfunction \( f_q \). Moreover, one can couple \( \mathcal{H}^{\beta,w} \) with a subsequence of \( A_N^{\beta,w}, N \in \mathbb{N} \) along which, almost surely,
\[
(4.2) \quad \lim_{N \to \infty} \Lambda_{q,N} = \Lambda_q \text{ and } \lim_{N \to \infty} \|v_{q,N} - f_q\|_{L^2([0,\infty))} = 0, \quad q = 1, 2, \ldots,
\]
where \( \Lambda_1,N < \Lambda_2,N < \cdots < \Lambda_N,N \) and \( v_{1,N}, v_{2,N}, \ldots, v_{N,N} \) are eigenvalues and corresponding eigenfunctions of \( A_N^{\beta,w} \). Along the same subsequence, the standard Brownian motion \( W \) in the definition of \( \mathcal{H}^{\beta,w} \) arises in the almost sure limit (1.13).

Next, we present an alternative formula for the kernel \( K_T^{\beta,w} \) of (1.14), to be used in the proof of Proposition 1.8.
Lemma 4.2. For all $\beta > 0$, $w \in \mathbb{R}$ and $T > 0$, define the kernels

\begin{equation}
K_\beta^T(x, y) = \exp\left(-\frac{(x-y)^2}{2T}\right) \frac{1}{\sqrt{2\pi T}} \cdot E_{\tilde{W}^x} \left[ \mathbf{1}_{\{\min_{0 \leq t \leq T} \tilde{W}_t^x > 0\}} \exp \left( -\int_0^T \frac{\tilde{W}_t^x}{2} \, dt + \int_0^\infty \frac{L_T^0(\tilde{W}_t^x)}{\sqrt{\beta}} \, dW_a - w \frac{L_T^0(\tilde{W}_t^x)}{2} \right) \mid \tilde{W}_T^x = y \right]
\end{equation}

and

\begin{equation}
K_{\beta,w}^T(x, y) = \frac{2}{\sqrt{2\pi T}} \cdot E_{\tilde{W}^x} \left[ \mathbf{1}_{\{\min_{0 \leq t \leq T} \tilde{W}_t^x \leq 0\}} \exp \left( -\int_0^T \frac{\tilde{W}_t^x}{2} \, dt + \int_0^\infty \frac{L_T^0(\tilde{W}_t^x)}{\sqrt{\beta}} \, dW_a - w \frac{L_T^0(\tilde{W}_t^x)}{2} \right) \mid \tilde{W}_T^x = y \right],
\end{equation}

where $\tilde{W}^x$ is a Brownian motion started at $x$, independent of $W$. Then,

\begin{equation}
K_{\beta,w}^T(x, y) = K_\beta^T(x, y) + K_{\beta,w}^T(x, y), \quad x, y \geq 0.
\end{equation}

Proof. With $R^x := |\tilde{W}^x|$, the formula for $K_{\beta,w}^T$ in (4.4) can be rewritten as

\begin{equation}
\exp\left(-\frac{(x-y)^2}{2T}\right) \frac{1}{\sqrt{2\pi T}} \cdot E_{\tilde{W}^x} \left[ \exp \left( -\int_0^T \frac{\tilde{W}_t^x}{2} \, dt + \int_0^\infty \frac{L_T^0(\tilde{W}_t^x)}{\sqrt{\beta}} \, dW_a - w \frac{L_T^0(\tilde{W}_t^x)}{2} \right) \mid \tilde{W}_T^x = y \right]
\end{equation}

\begin{equation}
+ \exp\left(-\frac{(x+y)^2}{2T}\right) \frac{1}{\sqrt{2\pi T}} \cdot E_{\tilde{W}^x} \left[ \exp \left( -\int_0^T \frac{\tilde{W}_t^x}{2} \, dt + \int_0^\infty \frac{L_T^0(\tilde{W}_t^x)}{\sqrt{\beta}} \, dW_a - w \frac{L_T^0(\tilde{W}_t^x)}{2} \right) \mid \tilde{W}_T^x = -y \right].
\end{equation}

Next, we decompose the first expectation in (4.6) according to the events

\begin{equation}
\left\{ \min_{0 \leq t \leq T} \tilde{W}_t^x > 0 \right\} \quad \text{and} \quad \left\{ \min_{0 \leq t \leq T} \tilde{W}_t^x \leq 0 \right\},
\end{equation}

and note that, on the former event, $|\tilde{W}^x| = \tilde{W}^x$ and $L_T^0(\tilde{W}^x) = 0$.

In addition, by the strong Markov property and the symmetry about 0 of Brownian motion, instead of conditioning on $\tilde{W}_T^x = -y$ in the second expectation of (4.6), we can condition on $\min_{0 \leq t \leq T} \tilde{W}_t^x \leq 0, \tilde{W}_T^x = y$. This operation, in turn, is equivalent to inserting $\mathbf{1}_{\{\min_{0 \leq t \leq T} \tilde{W}_t^x \leq 0\}}$ into the expectation, conditioning on $\tilde{W}_T^x = y$ and normalizing the result by $P\left[ \min_{0 \leq t \leq T} \tilde{W}_t^x \leq 0 \mid \tilde{W}_T^x = y \right]$. Computing

\begin{equation}
P\left[ \min_{0 \leq t \leq T} \tilde{W}_t^x \leq 0 \mid \tilde{W}_T^x = y \right] = e^{-2xy/T}
\end{equation}
from the joint density of the running minimum and the current value of a Brownian motion (see e.g. [24, Chapter III, Exercise 3.14]) and observing

\[
e^{2xy/T} \cdot \frac{\exp\left(-\frac{(x+y)^2}{2T}\right)}{\sqrt{2\pi T}} = \frac{\exp\left(-\frac{(x-y)^2}{2T}\right)}{\sqrt{2\pi T}}
\]

we arrive at the right-hand side of (4.5). □

We are now ready to prove Proposition 1.8.

Proof of Proposition 1.8. (a). The identity (1.19) follows from Theorem 1.7 by the same arguments as were used to obtain [13, Corollary 2.12] from Theorem 2.8 therein. One only needs to replace every reference to the main result of [26] by a reference to Proposition 4.1, the pointer to [13, Lemma 6.1] by a pointer to (1.5), and the assertion that the eigenvalues of \(-\frac{1}{2}H^\beta\) tend to \(-\infty\) by the same statement for \(-\frac{1}{2}H^{\beta,w}\) (cf. Proposition 4.1).

(b), (c). We proceed to the almost sure Hilbert-Schmidt property of \(U^{\beta,w}_T\), for each \(T > 0\). In view of Lemma 4.2, it is enough to show that

\[
E\left[ \int_0^\infty \int_0^\infty \left| K^\beta_T(x,y) + K^{\beta,w}_T(x,y) \right|^2 \, dx \, dy \right] < \infty.
\]

Since

\[
E\left[ \int_0^\infty \int_0^\infty K^\beta_T(x,y)^2 \, dx \, dy \right] < \infty
\]

is established in [13, proof of Lemma 5.1], it suffices to check

\[
\int_0^\infty \int_0^\infty E\left[ K^{\beta,w}_T(x,y)^2 \right] \, dx \, dy < \infty.
\]

Next, we estimate \(E\left[ K^{\beta,w}_T(x,y)^2 \right] \) by moving the square function into the expectation \(E_{\tilde{W}^x}[\cdot | \tilde{W}^x_T = y] \), dropping the indicator random variable, employing

\[
L^a_f(\bar{W}^x)^2 = (L^a_f(\bar{W}^x) + L^{-a}_f(\bar{W}^x))^2 \leq 2L^a_f(\bar{W}^x)^2 + 2L^{-a}_f(\bar{W}^x)^2, \quad a \geq 0,
\]

and evaluating the expectation with respect to \(W\):

\[
E\left[ K^{\beta,w}_T(x,y)^2 \right] \leq \frac{2 \exp\left(-\frac{(x-y)^2}{2T}\right)}{\pi T}
\]

\[
\cdot E\left[ \exp\left(-\int_0^T |\tilde{W}^x_t| \, dt + \int_{-\infty}^\infty \frac{4L^a_f(\bar{W}^x)^2}{\beta} \, da - 2wL^0_f(\bar{W}^x)\right) | \tilde{W}^x_T = y \right].
\]

According to Hölder’s inequality, the latter expectation is at most

\[
E\left[ \exp\left(-\int_0^T 3|\tilde{W}^x_t| \, dt\right) | \tilde{W}^x_T = y \right]^{1/3} \cdot E\left[ \exp\left(\int_{-\infty}^\infty \frac{12L^a_f(\bar{W}^x)^2}{\beta} \, da\right) | \tilde{W}^x_T = y \right]^{1/3}
\]

\[
\cdot E\left[ e^{-6wL^0_f(\bar{W}^x)} | \tilde{W}^x_T = y \right]^{1/3}.
\]
Thanks to $|\tilde{W}^z_T| \geq \tilde{W}^z_T$, the identity in distribution
\begin{equation}
(4.16) \quad \left( \tilde{W}^z_T : t \in [0, T] \mid \tilde{W}^z_T = y \right) \overset{d}{=} \left( \tilde{W}^0_T + (1 - \frac{t}{T})x + \frac{t}{T}y : t \in [0, T] \mid \tilde{W}^0_T = 0 \right),
\end{equation}
and $(1 - \frac{t}{T})x + \frac{t}{T}y \geq x \land y$, the first factor in (4.15) is bounded by
\begin{equation}
(4.17) \quad e^{-T(x \land y)} E \left[ \exp \left( - \int_0^T 3\tilde{W}^0_t \, dt \right) \left| \tilde{W}^0_T = 0 \right.) \right]^{1/3}.
\end{equation}

In addition, the coupling of [13, Proposition 4.1] reveals the random variable $\int_{-\infty}^x L^\beta_T (\tilde{W}) \, da$, conditioned on $\tilde{W}^z_T = y$, as the almost sure $N \to \infty$ limit of the left-hand side in [13 inequality (4.15)]. Thus, the second expectation in (4.15) can be controlled by the limit inferior of the corresponding exponential moment of the right-hand side in [13 inequality (4.15)]. Proceeding as therein we arrive at
\begin{equation}
(4.18) \quad E \left[ \exp \left( \int_{-\infty}^x \frac{12 L^\beta_T (\tilde{W})^2}{\beta} \, da \right) \left| \tilde{W}^z_T = y \right) \right]^{1/3} \leq C e^{C|x-y|},
\end{equation}
with a constant $C = C(\beta, T) < \infty$. Also, we see from [21, equation (3)] that the density of the local time at 0 of a Brownian bridge from $x'$ to $y'$ on $[0, 1]$ is
\begin{equation}
(4.19) \quad (z + x' + y') \exp \left( \frac{1}{2} \left( (x' - y')^2 - (z + x' + y')^2 \right) \right), \quad z > 0
\end{equation}
and from (4.8) that this local time vanishes with probability $1 - e^{-2x'y'}$. Hence,
\begin{equation}
(4.20) \quad E \left[ \exp \left( \theta L^0_T (\tilde{W}) \right) \right] \left| \tilde{W}^z_T = y \right) = 1 + \sqrt{\pi} \theta^2 e^{-2x'y'} \exp \left( \frac{(x' + y')^2}{2} \right) - \text{erfc} \left( \frac{-x' - y' + \theta}{\sqrt{2}} \right) \leq C(\theta) < \infty
\end{equation}
due to standard estimates for the complementary error function. All in all, it follows that the left-hand side in (4.12) is less or equal to
\begin{equation}
(4.21) \quad \int_0^\infty \int_0^\infty C \exp \left( - \frac{(x-y)^2}{C} - \frac{x \land y}{C} + C|x-y| \right) \, dx \, dy < \infty,
\end{equation}
where $C = C(\beta, w, T)$ is a finite positive constant.

We turn to the proof of the semigroup property in Proposition [13 b) and assume without loss of generality $T_1, T_2 > 0$. By the just established Hilbert-Schmidt property, it suffices to verify that, almost surely,
\begin{equation}
(4.22) \quad \mathcal{U}_{T_1}^{\beta,w} \mathcal{U}_{T_2}^{\beta,w} f = \mathcal{U}_{T_1 + T_2}^{\beta,w} f
\end{equation}
on a countable dense set of functions $f \in L^2([0, \infty))$. Fixing such a function $f$, writing it as the difference of its positive and negative parts, and applying Fubini's theorem we reduce the statement of Proposition [13 b) further to
\begin{equation}
(4.23) \quad \int_0^\infty K_{T_1}^{\beta,w} (x, z) K_{T_2}^{\beta,w} (z, y) \, dz = K_{T_1 + T_2}^{\beta,w} (x, y), \quad x, y \geq 0.
\end{equation}

Let us introduce the transition kernels
\begin{equation}
(4.24) \quad \gamma_T(x, y) := \frac{\exp \left( -\frac{(x-y)^2}{2T} \right) + \exp \left( -\frac{(x+y)^2}{2T} \right)}{\sqrt{2\pi T}}, \quad x, y \geq 0, \quad T > 0
\end{equation}
and the additive functionals

\[ F_T(R^x) := -\int_0^T \frac{R^x_t}{2} \, dt + \int_0^\infty \frac{L^0_\beta(R^x)}{\sqrt{\beta}} \, dW - \frac{L^0_\beta(R^x)}{2}, \quad T > 0. \]

Then,

\[ \int_0^\infty K^{\beta:w}_{T_1}(x, z)K^{\beta:w}_{T_2}(z, y) \, dz = \gamma_{T_1+T_2}(x, y) \]

\[ \cdot \int_0^\infty \frac{\gamma_{T_1}(x, z)\gamma_{T_2}(z, y)}{\gamma_{T_1+T_2}(x, y)} \operatorname{E}_{T_1} \left[ \left| e^{F_{T_1}(R^x)} \right|^2 \right] \operatorname{E}_{T_2} \left[ \left| e^{F_{T_2}(R^x)} \right|^2 \right] \, dz. \]

To identify the right-hand side of (4.29) with \( K^{\beta:w}_{T_1+T_2}(x, y) \) it remains to notice that the process \( R^x_t : t \in [0, T_1] \mid R^x_{T_1+T_2} = y \) therein can be sampled by

(a) picking a random point \( Z \) according to the density \( \frac{\gamma_{T_1}(x, z)\gamma_{T_2}(z, y)}{\gamma_{T_1+T_2}(x, y)} \), \( z > 0 \),

(b) conditional \( Z = z \), sampling processes \( R^{(1)} \) and \( R^{(2)} \) independently such that

\[ \{ R^{(1)}_t : t \in [0, T_1] \} \overset{\text{d}}{=} \{ R^x_t : t \in [0, T_1] \mid R^x_{T_1} = z \}, \]

\[ \{ R^{(2)}_t : t \in [0, T_2] \} \overset{\text{d}}{=} \{ R^y_t : t \in [0, T_2] \mid R^y_{T_2} = y \}, \]

(c) concatenating the paths of \( R^{(1)} \) and \( R^{(2)} \).

As with the semigroup property, for each \( T > 0 \), the symmetry property of the operator \( \mathcal{U}_T \) can be reduced to an assertion about its kernel:

\[ K^{\beta:w}_{T_1+T_2}(x, y) = K^{\beta:w}_{T_2+T_1}(y, x), \quad x, y \geq 0. \]

Since the transition kernels \( \gamma_{T'}, T' > 0 \) of the reflected Brownian motion \( R \) are symmetric, we have

\[ \{ R^x_t : t \in [0, T] \mid R^x_T = y \} \overset{\text{d}}{=} \{ R^y_{T-x} : t \in [0, T] \mid R^y_{T} = x \}, \]

and therefore (4.29). Finally, the non-negativity of \( \mathcal{U}^{\beta:w}_T \) follows by extending

\[ \int_0^\infty (\mathcal{U}^{\beta:w}_T f)(x) f(x) \, dx = \int_0^\infty (\mathcal{U}^{\beta:w}_{T/2}(\mathcal{U}^{\beta:w}_{T/2} f))(x) f(x) \, dx = \int_0^\infty ((\mathcal{U}^{\beta:w}_{T/2} f)(x))^2 \, dx \geq 0, \]

for a fixed \( f \in L^2([0, \infty)) \), to the same almost sure property for all \( f \in L^2([0, \infty)) \) simultaneously, by means of the almost sure Hilbert-Schmidt property of \( \mathcal{U}^{\beta:w}_T \).

(d). To obtain the almost sure trace class property of \( \mathcal{U}^{\beta:w}_T \) we combine the spectral theorem for symmetric compact operators with the definition of the trace to find

\[ \text{Tr}(\mathcal{U}^{\beta:w}_T) = \sum_{q=1}^{\infty} e^{-T\Lambda_q/2}. \]

The latter sum is the square of the Hilbert-Schmidt norm of the symmetric Hilbert-Schmidt operator \( \mathcal{U}^{\beta:w}_{T/2} \) (see e.g. [15] Section 28, Exercise 11) and, thus, equals to

\[ \int_0^\infty \int_0^\infty K^{\beta:w}_{T/2}(x, y) K^{\beta:w}_{T/2}(y, x) \, dy \, dx = \int_0^\infty K^{\beta:w}_T(x, x) \, dx. \]

(e). For the \( L^2 \)-strong continuity in expectation of (1.20), without loss of generality we fix an integer \( p \geq 2 \), an \( f \) with \( \|f\|_{L^2([0, \infty))} = 1 \), and a sequence \( (t_n)_{n \in \mathbb{N}} \) in
[0, T + 1] converging to T such that \( t_\eta > 0 \) for at least one \( \eta \). Then, by applying \cite{18} Section 28, Theorem 71 to the commuting symmetric operators \( \mathcal{U}_q^{\beta;w} \), \( \eta \in \mathbb{N} \) and \( \mathcal{U}_q^{\beta;w} \), with at least one \( \mathcal{U}_q^{\beta;w} \) being compact, we can write \( f \) as \( \sum_{q=1}^{\infty} c_q f_q \), where \( f_q, q \in \mathbb{N} \) form an orthonormal basis of common eigenfunctions for \( \mathcal{U}_q^{\beta;w} \), \( \eta \in \mathbb{N} \) and \( \mathcal{U}_q^{\beta;w} \), and \( c_q, q \in \mathbb{N} \) are the corresponding coefficients. By Jensen’s inequality,

\[
E \left[ \left\| \mathcal{U}_q^{\beta;w} f - \mathcal{U}_q^{\beta;w} f \right\|_{L^2([0, \infty])}^p \right] = E \left[ \left( \sum_{q=1}^{\infty} c_q^2 \left( e^{-T \Lambda_q / 2} - e^{-t_\eta \Lambda_q / 2} \right)^2 \right)^{p/2} \right] \\
\leq E \left[ \sum_{q=1}^{\infty} c_q^2 \left( e^{-T \Lambda_q / 2} - e^{-t_\eta \Lambda_q / 2} \right)^p \right].
\]

The random variable \((\omega, q) \mapsto \left(e^{-T \Lambda_q (\omega)/2} - e^{-t_\eta \Lambda_q (\omega)/2}\right)^p\) tends to 0 in the \( \eta \to \infty \) limit \( P \times \sum_{q=1}^{\infty} \delta_{\omega, q} \) almost surely. Its uniform integrability is due to

\[
E \left[ \sum_{q=1}^{\infty} c_q^2 \left( e^{-T \Lambda_q / 2} - e^{-t_\eta \Lambda_q / 2} \right)^{2p} \right] \leq 2^{p-1} E \left[ 2 \left( e^{-p(T+1) \Lambda_1} + 1 \right) \right]
\]

and a bound on \( e^{-p(T+1) \Lambda_1} \) by the squared Hilbert-Schmidt norm of \( \mathcal{U}_q^{\beta;w} \), whose expectation has been controlled in the proof of part (c).

5. Functionals of the reflected Brownian bridge

In this section, we prove Theorem \ref{thm:main} Proposition \ref{prop:cor1} and Corollary \ref{cor:cor1} in the order stated. The key ingredient in the proof of Theorem \ref{thm:main} is the next lemma, which extends an argument of Hariya \cite{14}.

**Lemma 5.1.** Let \( r_t, t \in [0, 1] \) be a reflected Brownian bridge, \( \alpha > 0 \) and \( \psi_\alpha \) be the joint moment-generating function of

\[
\left( \int_0^1 r_t \, dt, \int_0^\infty \frac{L_0^q(r)^2}{2} \, dr \right| L_1^0(r) = \alpha \).
\]

Then, with the three-dimensional Bessel bridge

\[
db_t^\alpha/2 = \frac{1}{b_t^\alpha/2} \, dt - \frac{b_t^\alpha/2}{1-t} \, dt + d\tW_t, \quad b_t^\alpha/2 = \alpha/2
\]

and the joint moment-generating function \( \tilde{\psi}_\alpha \) of \( \left( \int_0^1 b_t^{\alpha/2} \, dt, \int_0^1 \tW_t \, dt \right) \), it holds

\[
\psi_\alpha(\theta_1, \theta_2) = e^{-\alpha \theta_1/2 \cdot \tilde{\psi}_\alpha(\theta_1 + 2\theta_2, -\theta_1/2)}, \quad \theta_1, \theta_2 \in \mathbb{R}.
\]

**Proof.** Define the function

\[
h(a) := \int_0^1 1_{\{r_t \leq a\}} \, dt = \int_0^a L_1^a(r) \, da',
\]

as well as the corresponding quantile function \( h^{-1}(t) := \inf \{ a \geq 0 : h(a) \geq t \} \). In \cite{22} Corollary 16(iii)](see also \cite{23} equation (8.20)), Pitman shows that

\[
\left( \frac{1}{2} L_1^{h^{-1}(t)}(r) : t \in [0, 1] \right| L_1^0(r) = \alpha \right) \overset{d}{=} \left( b_t^{\alpha/2} : t \in [0, 1] \right),
\]
which extends Jeulin’s theorem beyond the $\alpha = 0$ case. Relying on (5.5) we find

$$\left( \frac{1}{2} \int_0^1 \frac{1-t}{\theta_0^\alpha} \, dt, \int_0^1 \theta_0^\alpha \, dt \right)$$

$$\overset{d}{=} \left( \int_0^1 \frac{1-t}{L_1^{h-1}(r)} \, dt, \frac{1}{2} \int_0^1 L_1^{h-1}(r) \, dt \right)$$

$$\int_0^1 \frac{1-t}{\theta_0^\alpha} \, dt + \frac{1}{2} \int_0^1 L_1^{h-1}(r) \, dt = \alpha$$

(5.6)

Finally, a sequential application of (5.6) and (5.8) yields

$$\int_0^1 \frac{1-t}{\theta_0^\alpha} \, dt + \frac{1}{2} \int_0^1 L_1^{h-1}(r) \, dt = \alpha$$

On the other hand, (5.2) implies

$$\int_0^1 (1-t) \, d\theta_0^\alpha = \int_0^1 \frac{1-t}{\theta_0^\alpha} \, dt - \int_0^1 \theta_0^\alpha \, dt + \int_0^1 (1-t) \, d\tilde{W}_t.$$
Proof of Proposition 1.10. Let \( \tilde{r}_t, t \in [0, T] \) be a reflected Brownian bridge from 0 to 0 on \([0, T]\). By the definition of \( K_T^{\beta;w} \) in (1.14),

\[
(5.11) \quad K_T^{\beta;w}(0, 0) = \frac{2}{\pi T} \mathbb{E} \left[ \exp \left( -\int_0^T \frac{\tilde{r}_t}{2} \, dt + \int_0^\infty \frac{L_T^w}(r) \, \text{d}W_r - w \frac{L_T^w(\tilde{r})}{2} \right) \right].
\]

Conditional on \( \tilde{r} \), the integral \( \int_0^\infty \frac{L_T^w(r)}{\sqrt{\beta}} \, \text{d}W_r \) is Gaussian with mean 0 and variance \( \int_0^\infty \frac{L_T^w(r)^2}{\beta} \, \text{d}a \). Hence, by taking the expectation with respect to \( W \) first, we find

\[
(5.12) \quad \mathbb{E}[K_T^{\beta;w}(0, 0)] = \frac{2}{\pi T} \mathbb{E} \left[ \exp \left( -\int_0^T \frac{\tilde{r}_t}{2} \, dt + \int_0^\infty \frac{L_T^w(r)^2}{2 \beta} \, \text{d}a - w \frac{L_T^w(\tilde{r})}{2} \right) \right].
\]

At this point, the proposition is a consequence of

\[
(5.13) \quad \frac{1}{\pi T} \int_0^T \tilde{r}_t \, dt, \int_0^\infty L_T^w(r) \, \text{d}a, L_T^w(\tilde{r})
\]

which, in turn, is due to the scaling property of (reflected) Brownian bridges. \( \square \)

Proof of Corollary 1.13. In view of (4.19), the local time \( L_T^0(r) \) is a continuous random variable with the density \( \frac{\alpha}{4} e^{-\alpha^2/8} \) on \((0, \infty)\). Using this and Theorem 1.11 for the right-hand side of (1.22) we compute

\[
(5.14) \quad \mathbb{E}[K_T^{\beta;w}(0, 0)] = \frac{2}{\pi T} \int_0^\infty \alpha e^{-\alpha^2/8} \exp \left( -\frac{T^{1/2}w}{2} \right) \, \text{d}\alpha \cdot \mathbb{E} \left[ \exp \left( -\frac{T^{3/2}}{2} \left( \int_0^T r_t \, dt - \frac{1}{2} \int_0^\infty L_t^0(r) \, \text{d}a \right) \right) \bigg| L_t^0(r) = \alpha \right] \, \text{d}\alpha
\]

\[
= \frac{2}{\pi T} \int_0^\infty \alpha e^{-\alpha^2/8} \exp \left( -\frac{T^{1/2}w}{2} \frac{\alpha}{2} + \frac{T^{3/2} \alpha}{8} + \frac{T^3}{96} \right) \, \text{d}\alpha
\]

\[
= \frac{e^{\alpha^2} \left( 8 + \sqrt{2\pi} e^{T(4w^2)/32} \sqrt{T - 4w} \left( \text{erf} \left( \frac{\sqrt{T - 4w}}{4\sqrt{2}} \right) + 1 \right) \right)}{4\sqrt{2\pi T}}.
\]

which simplifies to the right-hand side of (1.20). \( \square \)
