ABSTRACT
Despite serious health risks in humans and wild life, the underlying mechanisms that explain gene-environment effects of chemical toxicants are largely unknown. Polychlorinated biphenyls (PCBs) are one of the most ubiquitous environmental toxicants worldwide, with reported epidemiological evidence for reproductive and neurocognitive anomalies in humans. Here, we show that Aroclor 1254, a mixture of structurally distinct PCBs, causes preterm birth in IL-10−/− mice at a dose that does not show any effects in wild type mice, highlighting the significance of interleukin 10 (IL-10) as an anti-toxicant cytokine. Aroclor 1254-treated IL-10−/− mice demonstrated increased amniotic fluid, intrauterine growth restriction, and reduced litter size with postnatal neuromotor defects. Further, our results identify aquaporin 1 (AQP1), a potent effecter of fluid volume regulation and angiogenic activity, as a novel placental target of PCBs. In vivo or in vitro exposure to Aroclor 1254 coupled with IL-10 deficiency significantly reduced the protein content of AQP1. Reduced uterine AQP1 levels were associated with defective spiral artery transformation. Importantly, recombinant IL-10 reversed PCB-induced in vivo and in vitro effects. These data demonstrate for the first time that the IL-10-AQP1 axis is a novel regulator of PCB-induced in utero effects.

INTRODUCTION
The health consequences of environmental toxicants are likely to have critical effects during in utero fetal development because of the complex signaling cascades, high cellular proliferation rates, and differentiation events. Mammalian reproduction involves a complex but highly choreographed sequence of molecular processes. These processes include interactions between the hormonally stimulated uterus and the developing blastocyst, implantation, placental and fetal development, and parturition (1,2). Although the hormonal milieu, metabolic changes, and placental microenvironment are programmed in a pregnancy compatible manner, pregnancy presents itself as an immunological and hormonal paradox (3,4). The role of steroid hormones is well known in uterine receptivity, implantation, local immune modulation, and pregnancy success (5). If not temporally produced and regulated, their dysfunction lead to infertility or pregnancy loss. Man-made chemicals like polychlorinated biphenyls (PCBs) act like hormones and interfere with their cognate receptor functions impacting normal biological processes (6,7). Although the genotoxic effects of PCBs have been investigated intensively and epidemiological studies have highlighted their health risks (6,7), the mechanisms responsible for reproductive and neuro-developmental effects still remain enigmatic. The overarching goal of our studies is to identify unknown pathways and targets that impart adverse effects on pregnancy. In this study, we directed our efforts toward establishing an experimental system to evaluate in utero gene-environment effects of PCBs using wild type mice and their counterparts deficient in pregnancy compatible anti-inflammatory cytokines such as interleukin 10 (IL-10).

IL-10 is a potent anti-inflammatory cytokine that controls inflammatory insult in most organs, particularly at the maternal-fetal interface. IL-10 is produced by gestational tissue and maternal immune cells in the intra-uterine microenvironment in humans (8,9) and in mice...
We and others have reported that IL-10−/− mice experience preterm birth and resorptions in response to low doses of inflammatory triggers such as lipopolysaccharide (LPS) (11,12), or poly I:C (13). Importantly, the pregnancy outcome in treated IL-10−/− mice can be rescued by giving an exogenous dose of IL-10 (11,14). We have also demonstrated poor IL-10 production in placental and decidual tissues from preterm labor deliveries and missed abortions (15,16). These data suggest that an inflammatory environment coupled with genetic stress (IL-10 deficiency) may lead to adverse pregnancy outcomes. In consideration of these observations, we hypothesize that exposure to toxicants such as PCBs mimic physiological counterpart of inflammation that predisposes to adverse pregnancy outcomes when combined with genetic deficiency in loci crucial for pregnancy success such as IL-10.

Polychlorinated biphenyls (PCBs) are chlorinated aromatic hydrocarbon compounds consisting of a group of 209 structurally diverse congeners, identified based on the position of chlorine atoms (7). Since the start of their manufacture in the 1920s until their ban in late 1970s, PCBs were globally valued for their non-inflammability, high heat and chemical stability and thus were used widely in a multitude of commercial and industrial applications (7,17). Improper disposal and accidental release of these compounds led to their introduction into the environment, placing them in the list of widespread environmental contaminants. Subsequently, their lipophilicity facilitated their bioaccumulation in the food chain and bio-concentration at successively higher levels (6,18-21). PCBs have now been detected globally, in different environmental matrices, wild life, food and humans (6,18,20). Convincing evidence exist for their toxicity, both in humans as well as in laboratory animals (7). From epidemiological studies in humans it has been observed that exposure to PCBs causes various reproductive anomalies that include irregular and shorter menstrual cycles, delayed conception, miscarriage, reduced lactating time, low birth weight, preterm birth, small for gestational age infants and higher incidence of stillbirths and mortality among children (22-27). PCB congeners may work in an aryl hydrocarbon receptor (AhR) dependent or independent pathway (6,7,28). Despite the knowledge that PCBs affect either AhR or estrogen receptor (ER) signaling, there is a paucity of molecular mechanisms underlying the most sensitive developmental effects of PCBs, and thus new pathways and targets need to be identified.

Aroclor 1254 is a mixture of more than one hundred different PCB congeners and may impart cumulative adverse effects on female reproductive health (29,30). In this study, we show that Aroclor 1254 exposure induces preterm birth in IL-10−/− mice with reduced litter size and birth weight, increased amniotic fluid, and postnatal neurocognitive defects. Importantly, we have identified aquaporin 1 (AQP1) as a novel target of PCB action at the maternal-fetal interface. Our findings for the first time provide direct experimental evidence for a protective role of IL-10 against PCBs exposure. These findings may have implications for the understanding and management of environmental toxicant-induced female reproductive anomalies in humans.

**EXPERIMENTAL PROCEDURES**

*Mice and in vivo procedures* - All animal protocols were approved by the Lifespan Institutional Animal Care and Use Committee. Mice were housed and mated in a specific pathogen-free facility under the care of the Central Research Department of Rhode Island Hospital. All mating experiments were repeated at least three times with at least three mice per treatment. The day of vaginal plug appearance was designated gestational day (gd) 0. We administered daily i.p injection of 500 µg Aroclor 1254 (Sigma-Aldrich, MO, USA) per mouse or an equivalent volume (100 µl) of control vehicle (corn oil) to pregnant C57BL/6 wild type mice or their IL-10−/− counterparts from gd 4 to 12. We allowed one set of mice in all matings to deliver the pups. We recorded the time of birth and the litter size. Newborn pups were observed for loss of righting reflex during first 21 days of their lives. Pups were placed on a horizontal surface and righting reflex was expressed in terms of time required for a pup to turn over its four feet on ground when placed on its side (33).

We euthanized another set of pregnant mice (n=6) on gd 13 for molecular and immunological analyses. Uterine horns were examined for placental or fetal pathology. We
collected amniotic fluid on gd 13 by using tuberculin syringe and recorded the placental and fetal weights. Utero-placental tissue was snap frozen for biochemical and gas chromatography analysis and also fixed in formalin for histopathology. For rescue experiments, recombinant mouse IL-10 (R&D Systems, MN, USA) at the doe of 500 ng/ mouse or saline was injected twice on gd 5 and 8 along with Aroclor 1254 (500 µg/mouse) as described above. One set of animals was allowed to deliver pups and time required for a pup to turn over (Righting Reflex) was recorded as described earlier. Other set was euthanized on gd 13 for experimental analysis.

Semi-quantitative RT-PCR- Total RNA was isolated from utero-placental tissue using the RNeasy kit (Quiagen, CA, USA) in accordance with the manufacturer’s protocol. Total RNA was used for cDNA synthesis by reverse transcription with SuperScript III first-strand synthesis system for RT-PCR (Invitrogen, CA, USA) in accordance with the manufacturer’s instructions. Semi-quantitative RT-PCR reactions were set up for AQP1, 3, 8, 9 and β-Actin using PTC-100 Peltier thermocycler. The primer sets for AQP1,3,8 and 9 and β-actin were as follows: AQP1, sense 5′-TGC GTT CTG GCC ACC ACT GAC-3′ and anti-sense 5′-GAT GTC GTC AGC ATC CAG GTC-3′ (326 bp product); the AQP3, sense 5′-CTG GAC GCT TTC ACT GTG GGC-3′ and anti-sense 5′-ATC TGC TCC TTG TGT TTC ATG-3′ (307 bp product); the AQP8, sense 5′-CAG CCT TTG CCA TCG GCC-3′ and anti-sense 5′-ATC TGC TCC TTG TGT TTC ATG-3′ (355 bp product); the AQP9, sense 5′-CTG GAC GCT TTC ACT GTG GGC-3′ and anti-sense 5′-CTT GAA CCA CTC CAT CCT GCG-3′ (299 bp product) and the β-actin sense 5′-TCT TCT GAG AAG GAC CGA GCC-3′ and anti-sense 5′-CCT GAA CCA CTC CAT CCT GCG-3′ (299 bp product) and the β-actin sense 5′-TCT TCT GAG AAG GAC CGA GCC-3′ and anti-sense 5′-CTT CAA CC TCG GCC-3′ (457 bp product). The optimal RT–PCR conditions were standardized for each product. PCR products were separated by electrophoresis on 2% agarose gels and stained with 0.01% ethidium bromide. Images were recorded using Chemi Doc XRS gel imager.

Cell lines and cell culture- We used immortalized first trimester trophoblast cell line HTR8 with properties of invasive extravillous cytotrophoblasts (48). We obtained human umbilical vein endothelial cells (HUVEC) from Cambrex and cultured in EBM-2 medium (Cambrex, NJ, USA). We maintained all the cells under standard culture conditions of 5% CO2 at 37ºC. Use of commercially available HUVECs was limited to early and limited passage. Cells were grown to 80% confluence prior to their use in experiments.

Western blotting- We separated tissue and cellular lysates on 12% SDS–polyacrylamide gels and blotted onto PVDF membranes and probed with antibodies for AQP1, 3, 8 or 9 (Santa Cruz Biotechnology, CA, USA) and β-actin (Biovision, CA, USA). We used ECL chemiluminescence (Amersham Biosciences, NJ, USA) to visualize the bands and recorded them using Konica SRX 101A developer. Densitometric analysis were carried out using Gel-Pro-Analyzer (Media Cybernetics, MD, USA)

Immunohistochemistry- Individual utero-placental units were obtained on gd 13 and fixed with 10% buffered formalin. Fixed tissue was processed for mounting 5 µm sections on glass slides and immunostaining as described (11). Tissue slides were stained with a primary antibody to AQP1 (Santa Cruz Biotechnology) or control isotype IgG (Santa Cruz Biotechnology). We then acquired the images with a Nikon Eclipse 80i microscope (NiKon) at 10x magnification. A standard procedure was followed for hematoxylin and eosin staining (11). Morphometric analysis of spiral arteries was carried out using the SPOT Advanced software (Diagnostic Instruments, Inc, MI, USA) at 40x magnification (Nikon Eclipse 80i microscope). Average area of the spiral arteries of at least six spiral arteries per implantation site were calculated from three independent animals per group.

Flow cytometry- We evaluated the surface expression of AQP1, 3, 8 or 9 on human trophoblast cells in response to Aroclor 1254 treatment by immunostaining and FACS analysis (Becton Dickinson, NJ, USA) as described previously (45). Negative controls were performed by incubating the cells with isotype-matched antibodies.
**In vitro angiogenesis assay** - We examined the ability of Aroclor 1254 to disrupt the capillary network of endovascular cross talk between endothelial cells and trophoblasts using a three dimensional dual cell co-culture model as described previously (45). Briefly, 48-well culture plates were coated with 0.1 ml of Matrigel (BD Biosciences, CA, USA) and allowed to gelatinize at 37°C for 30 min. Trophoblasts or endothelial cells (2.5 x 10⁴), labeled with cell tracker green CMFDA or cell tracker red CMTMR (Molecular Probes, OR, USA) respectively were co-cultured (1:1) in the presence of 10% normal pregnancy serum (NPS) spiked with different concentrations of Aroclor 1254 (1, 10 and 25 µg/ml). The spontaneous interaction and endothelial cell-directed tube formation by trophoblasts was monitored and recorded after 12-14 hrs incubation under standard culture conditions using florescence microscopy (Nikon Eclipse TS 100 coupled with CCD camera, 4x magnification). Similarly, the single cell tube formation assay was carried out with labeled endothelial cells. Using the MetaVue® software, the phase-contrast and red fluorescent images in single cell tube assay or the red and green fluorescent images from dual cell co-cultures were overlaid. The average number of tubes/vacuoles formed was quantified by counting the number of tube like structures formed by connected capillary bridge in four different fields by two independent investigators. To study the involvement of AQP1 in this cross talk, prior to the assay, AQP1 expression on trophoblast cells was blocked by using AQP1 blocking antibody (Chemicon, CA, USA). For the rescue of Aroclor 1254-induced disrupted cross talk, 1 µM estradiol (Sigma-Aldrich, MO, USA) or different doses of recombinant human IL-10 (R&D Systems, MN, USA) were added in the culture medium and the assay was carried out as described earlier.

**Gas chromatography analysis** - For the extraction and analysis of samples by gas chromatography, a modified EPA method was followed (49). Briefly, the target tissues were extracted using acetone:hexane (1:1) mixture (5 ml x 3) in an ultrasonic bath for 10 min. The combined supernatant was transferred to a 40 ml glass vial. The recovered supernatant was then dried under nitrogen and then transferred to a 4 ml vial using hexane. 1 ml of sulfuric acid was added and after vigorous shaking supernatant was transferred to another 4 ml vial. The recovered supernatant was dried under nitrogen and transferred to a 2 ml vial using hexane. Hexane was again dried under nitrogen gas and finally 0.5 ml of toluene was added. Extracts were analyzed on an Agilent Tech HP6890 Gas chromatography system equipped with a HP 5 MS column (30m X 0.25 mm i.d X 0.25 mm thickness) and a Ni µ-ECD detector. The injector temperature was 280°C, and the detector temperature was 290 °C. The oven temperature program was 20°C/min from 60°C to 140°C, 6°C/min from 140°C to 160°C, 15°C/min from 160°C to 220°C, 20°C/min from 220°C to 280°C hold for 5 min.

**Statistics** - We performed statistical analysis using Students “t” test. When required, comparisons between multiple groups were made by analysis of variance using ANOVA. A probability level of 0.05 was considered significant.

**RESULTS**

Aroclor 1254 administration induces premature birth in IL-10⁻/⁻ mice. We initially examined the dose dependent effects of Aroclor 1254 when injected i.p. in wild type or IL-10⁻/⁻ pregnant mice. Based on pilot experiments, we established that Aroclor 1254 injected from gestational day (gd) 4 through gd 10 or 12 at 500 µg/mouse had adverse effects on pregnancy outcome. Although this dose showed no effect in wild type mice, it induced preterm birth in IL-10⁻/⁻ mice. It is possible that not all PCB congeners in Aroclor 1254 impart adverse pregnancy outcome thus requiring a seemingly high dose of this PCB mixture for optimal effects. We next performed an expanded set of experiments involving multiple matings using the above described dose of Aroclor 1254 and i.p. injections. As shown in Table 1, Aroclor 1254 induced preterm delivery only in IL-10⁻/⁻ mice on gd 17 compared to term delivery (gd 20) in vehicle (corn oil) treated IL-10⁻/⁻ mice and vehicle or Aroclor 1254 treated wild type animals. Preterm delivery in IL-10⁻/⁻ mice was accompanied by reduced litter size, placental weight, and fetal weight. Multiple mating experiments resulted in similar pregnancy outcomes. These results
demonstrate that IL-10 deficiency is associated with significant adverse \textit{in utero} effects of PCB.

\textbf{Aroclor 1254 treatment causes defective righting reflexes}. Since neurocognitive anomalies have been reported in epidemiological studies of children born to PCB-exposed mothers (31,32), we examined whether newborns from Aroclor 1254-treated IL-10\(^{-/}\) mice suffered from any neurological defects. Righting reflex, a developmental neurologic activity, is a postural reaction that enables an animal to turn over its four feet on ground when placed on its back or side. The righting reflex has been previously used for newborns of rodents (33). We monitored PCB-induced loss of righting reflex in pups born to wild type and IL-10\(^{-/}\) mice. Examination of 7 day old pups from corn oil or Aroclor 1254-treated wild type and IL-10\(^{-/}\) mice revealed that pups born to Aroclor 1254-treated IL-10\(^{-/}\) mice (n=13) failed to exhibit righting reflexes in multiple experiments (Fig. 1a). Since pups born to PCB-treated IL-10\(^{-/}\) mice were born prematurely, we repeated these observations on multiple occasions until 21 day of life and observed similar righting reflex defects.

\textbf{Aquaporin 1 is a novel target of Aroclor 1254 in utero-placental tissue}. To our surprise, Aroclor 1254-treated IL-10\(^{-/}\) mice appeared to have increased amniotic fluid volume. In humans, amniotic fluid volume dysregulation and risk factors have been associated with intraterine infections and inflammation, preterm birth, and postnatal developmental defects (34-36). We quantified amniotic fluid volume in Aroclor 1254-treated animals collected on gd 13 as described in Methods and found a 2 fold increase in amniotic fluid (Fig. 1b). These data imply that either prematurity or PCB-mediated defects in fluid volume regulation cause amniotic fluid increase in pregnant IL-10\(^{-/}\) mice in response to Aroclor 1254 exposure. Our intriguing observations on preterm delivery and increased amniotic fluid in IL-10\(^{-/}\) mice in response to Aroclor 1254 treatment (Table 1 and Fig. 1b) point to angiogenesis-linked mechanisms. Angiogenesis and fluid volume regulation play critical roles in normal placentation and fetal development. Aquaporins, first described as water channels (37), have been shown to be present in the placenta (38) and to participate in angiogenesis (39) and fluid volume regulation (40,41). We hypothesized that aquaporins (AQP) could serve as novel targets of PCBs for preterm delivery and increase in amniotic fluid. AQP 1, 3, 8, and 9 have been shown to be expressed in the placental microenvironment (38). To test our hypothesis, we evaluated the expression of these AQP in utero-placental tissue obtained on gd 13 by semi-quantitative RT-PCR (Fig. 2a) and immunoblotting (Fig. 2b and c). We did not detect any differences in the mRNA expression of AQP1, 3, 8, and 9 in tissue from untreated or Aroclor 1254-treated wild type or IL-10\(^{-/}\) mice (Fig. 2a). Surprisingly, we observed a significant reduction in the amounts of AQP1 protein in Aroclor 1254-treated IL-10\(^{-/}\) mice compared to other AQP (Fig. 2b and c). It is thus possible that PCBs only affect post-transcriptional or post-translational regulation of AQP1 and further experiments are warranted to decipher such pathways.

We next attempted to verify Aroclor 1254-mediated \textit{in vivo} effects on AQP1 expression by immunohistochemical analysis of formalin-fixed utero-placental tissue from IL-10\(^{-/}\) and wild type mice. As shown in Fig. 2d, significant staining for AQP1 was observed in gd 13 utero-placental tissue from corn oil-treated IL-10\(^{-/}\) mice. The section is marked to identify the mesometrial zone (M), decidua basalis (D), placental zone (P), and transformed spiral arteries (SA). AQP1 was strongly present around transformed spiral arteries and in the decidua basalis region. In contrast, AQP1 staining was poor in utero-placental tissue from Aroclor 1254-treated IL-10\(^{-/}\) mice, suggesting a pivotal role of this aquaporin in endovascular activity and angiogenesis leading to spiral artery remodeling. No obvious differences between treated and untreated conditions were observed in wild type mice for AQP1 staining (data not shown). Thus, we suggest that AQP1 is a novel target of Aroclor 1254 and its poor levels were associated with defective angiogenic processes at the maternal-fetal interface.

\textbf{Aroclor 1254 treatment disrupts spiral artery remodeling in IL-10\(^{-/}\) mice}.—Histological assessment and localization of AQP1 in the utero-placental tissue suggested adverse effects of Aroclor 1254 on spiral artery transformation. Physiological spiral artery transformation is a critical angiogenic event during placentation and
has been reported to be defective in preeclamptic and preterm labor deliveries in humans (42,43). Morphometric analysis of the H&E sections of uteroplacental units from multiple animals was carried out to confirm the toxicant-induced effects on spiral artery remodeling. Using SPOT™ Advanced software the diameters of spiral arteries opening into the myometrium were recorded. As shown in Fig. 2e and f, IL-10−/− mice exposed to Aroclor 1254 show dramatic reduction in diameter and area of the spiral arteries, suggesting that Aroclor 1254 significantly inhibited the transformation of these blood vessels. On the other hand, no significant changes were observed in tissue from wild type mice (Fig. 2f).

Aroclor 1254 treatment of human first trimester trophoblast cells results in inhibition of AQP1. As described above, mouse AQP1 is a potent target of PCBs. However, we can not preclude the possibility that Aroclor 1254-mediated effects on AQP1 were limited to the mouse maternal-fetal interface. To further demonstrate that AQP1 was also a PCB target at the human maternal-fetal interface, we measured protein levels of AQP1, 3, 8 and 9 in Aroclor 1254-treated human HTR8 cells, representing first trimester trophoblasts, by FACS analysis and immunoblotting. Notably, despite similar levels of expression in untreated cells, we detected significant inhibition of AQP1 when analyzed by FACS (Fig. 3a) without affecting AQP5 (Fig. 3b), AQP8 (Fig. 3c) and AQP9 (Fig. 3d). We further confirmed the Aroclor 1254-induced inhibition of AQP1 by Western blotting (Fig. 3e) and densitometry analysis (Fig. 3f). These results in Aroclor 1254 treated human extravillous trophoblast cells support our finding in IL-10−/− mice. Similar results were observed in other first trimester trophoblast cell lines, SWAN 71 and 3A (data not shown).

Inhibition of endovascular interactions between trophoblasts and endothelial cells by PCB and AQP1 blocking antibody. Based on the data presented above, we next aimed to demonstrate that inhibition of AQP1 by Aroclor 1254 treatment of HTR8 cells results in defective endovascular cellular interactions required for optimal spiral artery transformation. We and others have recently developed a three-dimensional culture system on matrigel that mimics endovascular cross talk between trophoblast cells and endothelial cells (44,45). We carried out trophoblast-endothelial cells interactions on matrigel in the absence or presence of Aroclor 1254, AQP1 blocking antibody, or Aroclor 1254 and estradiol. Doses of Aroclor 1254, AQP1 blocking antibody, and estradiol were determined based on pilot experiments. As shown in Fig. 4a, co-culture of HTR8 cells and HUVECs on matrigel leads to rapid formation of three- dimensional tube structures. Incubation in the presence of either Aroclor 1254(Fig. 4b) or AQP1 blocking antibody (Fig. 4c) disrupted tube formation between HTR8 cells and HUVEC cells. This demonstrated that PCB-mediated inhibition of AQP1 or its blocking by an antibody in trophoblast cells elicited detrimental effects on endovascular activity of these cells. On the other hand, estradiol blocked Aroclor 1254 effects and restored tube formation (Fig. 4d). Importantly, the rescue of tube formation by estradiol was due to reversal of Aroclor 1254-induced suppression of AQP1 (Fig. 4e). We also demonstrate that Aroclor 1254 strongly inhibited tube formation in a single cell culture of endothelial cells (Fig. 5h, lower panel), suggesting that PCBs have direct effect on endothelial cells. These effects are not due to poor cell survival of HTR8 or HUVECs as we did not detect any cell death in response to Aroclor 1254 treatment (data not shown).

IL-10 functions as anti-PCB cytokine. Pregnancy complications observed only in IL-10−/− mice exposed to Aroclor 1254 suggested a protective role of IL-10. However, pregnancy anomalies in these animals could also arise through non-IL-10 pathways. To demonstrate that IL-10 functions as an anti-PCB cytokine, we performed experiments to assess the ability of IL-10 to rescue PCB-mediated in vivo and in vitro effects. As shown in Fig.5a-i, administration of recombinant mouse IL-10 on gd 5 and 8 rescued the phenotypic and molecular anomalies induced by Aroclor 1254. IL-10 treatment rescued preterm birth caused by Aroclor 1254 in IL-10−/− mice (Fig. 5a), and prevented the toxicant-induced increase in amniotic fluid (Fig. 5b). Importantly, administration of recombinant IL-10 significantly reversed the Aroclor-1254-induced loss of righting reflex (Fig. 5c), suggesting a key role played by
IL-10 during pregnancy and post-natal neurodevelopment. Moreover, recombinant IL-10 reversed the Aroclor 1254-induced reduction in transformed spiral arteries in IL-10<sup>−/−</sup> mice (Fig. 5d and e). At the molecular level, IL-10 co-treatment reversed the Aroclor 1254-induced suppression of AQP1 expression in the placental tissue (Fig. 5f and g), implicating IL-10 as an anti-PCB cytokine. Moreover, recombinant human IL-10 rescued Aroclor 1254-induced disruption of three-dimensional tube formation involving endothelial cells alone or dual culture of endothelial cells and trophoblasts (Fig. 5h). Quantification of tube formation in response to different doses of Aroclor 1254 or in combination with different doses of recombinant IL-10 is graphically shown in Fig. 5i. While Aroclor 1254 disrupted in vitro endovascular interactions, co-treatment with recombinant IL-10 significantly rescued Aroclor 1254-mediated disruption in a dose dependent manner, supporting in vivo protective effects of IL-10 on spiral artery remodeling.

**Sensitivity of IL-10<sup>−/−</sup> mice to in utero anomalies is not associated with differential placental transport of Aroclor 1254.** Our in vivo data in IL-10<sup>−/−</sup> mice are intriguing but one could argue that IL-10<sup>+/+</sup> mice were more susceptible to PCBs compared to wild type mice because of excessive placental transport of the toxicant. Thus, we assessed placental and fetal presence of Aroclor 1254 in IL-10<sup>−/−</sup> and wild type mice. Placenta and fetus from corn oil and Aroclor 1254-treated wild type and IL-10<sup>−/−</sup> mice were processed for PCB extraction and analysis by gas chromatography. Optimal parameters were established for the Aroclor 1254 mixture and corn oil treated placenta. The data presented in Fig. 6 supports the notion that there was a similar placental and fetal exposure to PCBs in both wild type and IL-10<sup>−/−</sup> strains. It appears that all congener peaks of Aroclor 1254 were present in all tissues analyzed compared to total absence of these peaks in tissues from corn oil treated (control) IL-10<sup>−/−</sup> mice (Fig. 6) or their wild type counterparts (data not shown). These observations imply that the predisposition in IL-10<sup>−/−</sup> mice to preterm birth was not due to excessive or congener specific PCB transport in this strain.

**DISCUSSION**
treatment. Moreover, recombinant IL-10 reversed the PCB-induced decrease in spiral arteries, implying its protective role in at the maternal-fetal interface. These observations are further supported by IL-10-mediated rescue of PCB-induced disruption of tube formation in both single cell and dual cell three-dimensional models of angiogenesis. Given these observations, it will be important to examine the effects of single coplanar and non-coplanar congeners and reversal of their effects by IL-10. Although, estradiol was able to rescue the PCB-induced disruption of tube formation and suppression of AQP1 expression in vivo, pregnancy rescue experiments with administration of estradiol are not feasible. In this context, it is well documented that estrogen receptors are expressed at the maternal-fetal interface. However, for successful pregnancy outcome the levels of estrogen and progesterone are critical. The estrogen levels wane off once implantation takes place with concomitant increase in progesterone (50). It is thus possible that alterations in these highly choreographed levels of hormones due to exogeneous administration of estradiol would compromise pregnancy.

The identification of AQP1 as a novel PCB target at the maternal-fetal interface in mice and in human trophoblasts is noteworthy. AQPs were first identified as water channels and are small membrane proteins (37). Although there are 13 known mammalian proteins that increase permeability of not only water but other small molecules such as glycerol and urea, their individual presence is strictly organ specific (47). The placenta has been shown to express a spectrum of AQPs, particularly AQP1, 3, 8 and 9 (38). Importantly, AQP1 has been shown to regulate angiogenesis (39) and amniotic fluid volume (40,41,47). In this regard, our results on Aroclor1254-mediated inhibition of AQP1 are intriguing. Reduced AQP1 levels were associated with defective spiral artery transformation in IL-10 -/- mice and an AQP1 blocking antibody disrupted endovascular interactions between human trophoblast cells and endothelial cells in vitro. In addition, Aroclor 1254 treatment of human trophoblasts resulted in AQP1 inhibition and disruption of endovascular interaction with endothelial cells. We thus propose that AQP1 is a critical molecule in programming angiogenesis and spiral artery transformation in the pregnant uterus.

In the present study, our data clearly reveal novel targets and pathways for PCB-mediated effects that control highly choreographed events at the maternal-fetal interface and can lead to better understanding of gene-environment biology in general.

FOOTNOTES

We thank Kim Boekelheide and James Padbury for their thoughtful critique and suggestions for the manuscript. This work was supported in part by Superfund Basic Research Program Award (P42ES013660) and NCRR award (P20RR018728).

The abbreviations used are: PCB, polychlorinated biphenyls; AQP, aquaporins; HUVEC, human umbilical vein endothelial cells; A-1254, Aroclor 1254
FIGURE LEGENDS

Fig 1. Characterization of postnatal neurocognitive anomaly and amniotic fluid regulation in response to *in utero* exposure to Aroclor 1254 (A-1254). Panel (a) depicts righting reflex in 7 days old pups. Pups born to vehicle (corn oil) or A-1254-treated wild type mice and corn oil treated IL-10^-/- mice showed normal righting reflex, whereas pups born to IL-10^-/- mice treated with A-1254 showed loss of righting reflex (encircled in red). Panel (b) shows amniotic fluid volume dysregulation in A-1254-treated IL-10^-/- mice. No significant change was observed in amniotic fluid volume in wild type mice. Amniotic fluid was collected on gd 13 from at least 6 mice from each group. Values are mean +/- s.d. A-1254-treated mice showed a significant difference (* P<0.05).

Fig 2. A-1254 treatment inhibits the protein expression of AQP1. Panel (a) shows semi-quantitative RT-PCR for AQP1, 3, 8, and 9 mRNA expressions in utero-placental tissue from gd 13. A-1254 did not affect expression of any of aquaporins at mRNA level. Panel (b) shows Western blots for AQP1, 3, 8, and 9. A-1254 treatment reduces AQP1 protein level in IL-10^-/- mouse placenta while protein levels of AQP3, 8, and 9 remained unaltered. Panel (c) shows average densitometric analysis of intensities of AQP1, 3, 8, 9 protein bands normalized to β-actin from a number of experimental samples. A-1254 significantly reduced AQP1 protein levels in IL-10^-/- placental tissue. Panel (d) shows immunohistochemistry for AQP1 in utero-placental sections (10x magnification) from IL-10^-/- mice. A-1254 treatment reduced AQP1 protein staining and significantly changed the morphology of myometrium compared to tissue from corn oil-treated mice. Mesometrial zone (M), decidua basalis (D), placental zone (P), and transformed spiral arteries (SA) are marked, (10x magnification). Panel (e) shows the morphometry of representative spiral arteries in utero-placental sections from wild type and IL-10^-/- mice stained with H&E (40x magnification). A-1254 treatment of pregnant IL-10^-/- mice resulted in poor remodeling of spiral arteries as indicated by their reduced size as compared to those from corn oil-treated (vehicle) or wild type mice. The diameters of spiral arteries expressed as µm were measured and stamped using SPOT Advanced software. One representative data set is shown out of three experiments performed. Panel (f) represents quantitatively the average area of the spiral arteries of at least six spiral arteries per implantation site from three independent animals per group.

Fig 3. A-1254-mediated modulation of AQP1 protein levels in human trophoblast HTR8 cells. Representative FACS histograms are shown for (a) AQP1, (b) AQP3, (c) AQP8, and (d) AQP9 in response to 24 hr treatment of HTR8 cells with A-1254 (25 µg/ml). Panel (e) shows a Western blot for AQP1 levels in trophoblast HTR8 cells in response to A-1254. One representative data set is shown out of three experiments performed. Panel (f) shows the average densitometry values of AQP1 normalized to β-actin from three Western blot experiments.

Fig 4. Effect of A-1254 treatment or AQP1 blocking on endovascular interactions between HTR8 trophoblast cells and HUVECs. HUVECs (EC, labeled with red cell tracker) and HTR8s (labeled with green cell tracker) were cultured overnight on matrigel in presence or absence of A-1254. The capillary tube formation was recorded as described in Methods. Representative figures of EC-directed tube formation by HTR8 cells (4x magnification) are shown: (a) In presence of normal pregnancy serum (NPS), (b) trophoblasts pretreated with AQP1 blocking antibody, (c) in presence of NPS spiked with A-1254 (10 µg/ml), (d) in presence of NPS spiked with Estradiol (E2) (1 µM) and A-1254 (25 µg/ml). (e) Representative FACS analysis of AQP1 expression in trophoblast HTR8 cells showing E2-mediated rescue of AQP1 suppression. One representative data set is shown out of three separate experiments performed.
Fig 5. Recombinant IL-10 rescues PCB-induced in vivo and in vitro pregnancy anomalies. A-1254 (500 µg/ml, gd 4-12) or combination with mouse IL-10 (500 ng/mouse, gd 5 and 8) or corn oil (vehicle) was administered to IL-10−/− pregnant mice (n=3 per group). Panel (a) shows the IL-10-mediated rescue of pregnancy to term in A-1254-treated mice. Panel (b) shows the IL-10-mediated prevention of amniotic fluid volume increase due to A-1254 treatment. Panel (c) shows the average response time of righting reflex. IL-10 treatment significantly reversed A-1254-induced loss of righting reflex. Panel (d) shows representative spiral arteries in utero-placental sections from IL-10−/− mice stained with H&E (40x magnification). Recombinant IL-10 significantly reversed the A-1254-induced poor remodeling of spiral arteries to levels comparable to those from corn oil-treated (vehicle). Panel (e) represents quantitatively the average area of the spiral arteries of at least six spiral arteries per implantation site from three independent animals per group. Panel (f) shows the Western blot for AQP1 in placental tissue. IL-10 treatment neutralizes the AQP1 suppression caused by A-1254 treatment. Panel (g) shows the average densitometry values of placental AQP1 normalized to β-actin from three Western blot experiments. Panel (h, Upper panel) shows human IL-10-mediated (100 ng/ml) rescue of A-1254 (10 µg/ml)-induced disruption of angiogenesis on endothelial cell (labeled red)-trophoblast (labeled green) dual cell tube formation assay. Panel (h, Lower panel) shows IL-10-mediated (100 ng/ml) rescue of A-1254 (10 µg/ml)-induced disruption of angiogenesis on endothelial cell tube formation assay. The endothelial cells were labeled red and overlaid with phase contrast image. All the images were recorded at 4x magnification. Panel (i) shows the quantification of tube formation in dual cell and single cell models of angiogenesis with different doses of A-1254 or A-1254 (10 µg/ml) in combination with different doses of IL-10. The average number of tubes/vacuoles formed was quantified from triplicate experiments by counting the number of tube-like structures formed by connected capillary bridge in four different fields (4x magnification) by two independent investigators. Values are expressed as mean ± s.d. ** P<0.05.

Fig 6. Transplacental transport of A-1254. Frozen utero-placental tissue from corn oil or A1254-treated pregnant mice was processed for PCB content determination by gas chromatography as described in Methods. Representative gas chromatograms for (a) standard A-1254, (b) tissue from corn oil-treated wild type mice, (c) tissue from A1254-treated wild type mice, (d) tissue from IL-10−/− mouse, (e) wild type fetus, and (f) IL-10−/− fetus. Utero-placental and fetal tissues were collected on gd 13. One representative data set is shown out of four experiments performed.
Table 1: Aroclor 1254 induces preterm birth in C57BL/6 IL-10−/− mice

| Matings                     | Treatment | Preterm birtha | Litter size | Placental weightd | Fetal weighte |
|-----------------------------|-----------|----------------|-------------|-------------------|---------------|
| C57BL/6 x C57BL/6           | Vehicle   | 0/8            | 10.0±0.9    | 93.5±7.5          | 141.4±16.7    |
|                             | A-1254    | 0/9            | 8.3±1.0     | 90.9±5.3          | 136.7±15.7    |
| C57BL/6 IL-10−/− x C57BL/6 IL-10−/− | Vehicle | 0/7            | 9.0±1.0     | 92.9±7.7          | 136.2±17.1    |
|                             | A-1254    | 13/13          | 4.1±1.0*    | 81.1±6.1*         | 119.5±8.9*    |

a Birth on gd 17±0.5
b i.p injection of 100µl vehicle (corn oil) or 500 µg Aroclor 1254 (A-1254) per mouse from gd 4 to gd 12
c Number refer to the number of vaginal plug positive females
d Weight in mg on gd 13
* P<0.05 Student ‘t’ test
All values are expressed as mean ± s.d
Figure 1
Figure 2

(a) RT-PCR analysis showing expression levels of AQP1, AQP3, AQP8, AQP9, and β-actin in Wild type and IL-10−/− mice treated with Vehicle or A-1254.

(b) Western Blot analysis showing expression levels of AQP1, AQP3, AQP8, AQP9, and β-actin in Wild type and IL-10−/− mice treated with Vehicle or A-1254.

(c) Bar graph showing AQP1/β-actin, AQP3/β-actin, AQP8/β-actin, and AQP9/β-actin ratios in Wild type and IL-10−/− mice treated with Vehicle or A-1254.

(d) AQP1 Immunohistochemistry images showing staining in Wild type and IL-10−/− mice treated with Vehicle or A-1254.

(e) H&E staining images showing pathological changes in Wild type and IL-10−/− mice treated with Vehicle or A-1254.

(f) Bar graph showing average area of spiral arteries (µm²) in Wild type and IL-10−/− mice treated with Vehicle or A-1254.

*significant difference compared to Vehicle.
Figure 5

(a) Graph showing amniotic fluid (ml) across different birth (gestational day) stages for IL-10−/− and wild type mice with rIL-10 and A-1254.

(b) Graph showing the average amniotic fluid (ml) for IL-10−/− and wild type mice with rIL-10 and A-1254.

(c) Graph showing the average response time of fighting reflex (sec) for wild type and IL-10−/− mice with A-1254 and rIL-10.

(d) Images of tissue sections stained with IL-10−/−, A-1254, and A-1254+rIL-10.

(e) Graph showing the average area of sprout (mm²) for wild type and IL-10−/− mice with A-1254 and rIL-10.

(f) Western blot analysis of AQP1 and β-actin expression with Vehicle, A-1254, and A-1254+rIL-10.

(g) Bar graph showing ACP1/β-actin expression with Vehicle, A-1254, and A-1254+rIL-10.

(h) Images of tissue sections stained with EC, HTR8, A-1254, and A-1254+rIL-10.

(i) Graph showing the average number of tubes for A-1254, A-1254+HTR8, and EC with different concentrations of A-1254 and rIL-10.
Figure 6
The water channel aquaporin 1 is a novel molecular target of polychlorinated biphenyls for in utero anomalies
