SEMI-ORTHOGONAL DECOMPOSITIONS OF GIT QUOTIENT STACKS

ˇSPELA ˇSPENKO AND MICHEL VAN DEN BERGH

Abstract. If $G$ is a reductive group acting on a linearized smooth scheme $X$ then we show that under suitable standard conditions the derived category $\mathcal{D}(X^{ss}/G)$ of the corresponding GIT quotient stack $X^{ss}/G$ has a semi-orthogonal decomposition consisting of derived categories of coherent sheaves of rings on $X^{ss}/G$ which are locally of finite global dimension. One of the components of the decomposition is a certain non-commutative resolution of $X^{ss}/G$ constructed earlier by the authors. As a concrete example we obtain in the case of odd Pfaffians a semi-orthogonal decomposition of the corresponding quotient stack in which all the parts are certain specific non-commutative crepant resolutions of Pfaffians of lower or equal rank which had also been constructed earlier by the authors. In particular this semi-orthogonal decomposition cannot be refined further since its parts are Calabi-Yau.

The results in this paper complement results by Halpern-Leistner, Ballard-Favero-Katzarkov and Donovan-Segal that assert the existence of a semi-orthogonal decomposition of $\mathcal{D}(X/G)$ in which one of the parts is $\mathcal{D}(X^{ss}/G)$.

1. Introduction

1.1. Main result. Throughout $k$ is an algebraically closed base field of characteristic 0. All schemes are $k$-schemes. If $\Lambda$ is a right noetherian ring then we write $\mathcal{D}(\Lambda)$ for $\mathcal{D}^{b}_{\text{coh}}(\Lambda)$, the bounded derived category of right $\Lambda$-modules with finitely generated cohomology. Similarly for a noetherian scheme/stack $X$ we write $\mathcal{D}(X) := \mathcal{D}^{b}_{\text{coh}}(X)$ and if $\mathcal{A}$ is a quasi-coherent sheaf of noetherian algebras on a stack $\mathcal{X}$ then we write $\mathcal{D}(\mathcal{A})$ for $\mathcal{D}^{b}_{\text{coh}}(\mathcal{A})$.

Definition 1.1.1. Let $\mathcal{D}$ be a triangulated category. A semi-orthogonal decomposition $\mathcal{D} = (\mathcal{D}_i | i \in I)$ is a list of triangulated subcategories $(\mathcal{D}_i)_{i \in I}$ of $\mathcal{D}$ indexed by a totally ordered set $I$ such that

During part of this work she was also a postdoc with Sue Sierra at the University of Edinburgh. Partly she was supported by L’Oréal-UNESCO scholarship “For women in science”.

The second author is a senior researcher at the Research Foundation Flanders (FWO). While working on this project he was supported by the FWO grant G0D8616N: “Hochschild cohomology and deformation theory of triangulated categories”.

Substantial progress on this project was made during visits of the authors to each other’s host institutions. They respectively thank the University of Hasselt and the University of Edinburgh for their hospitality and support.
Theorem 1.1.2. \(\pi\) is generated by \(D_i, i \in I\). I.e. it is the smallest triangulated subcategory of \(D\) containing \(D_i, i \in I\).

(2) \(\text{Hom}(D_i, D_j) = 0\) for \(j < i\).

Let \(X\) be a scheme. A presheaf of triangulated categories \(\widetilde{E}\) on \(X\) consists of triangulated categories \(\widetilde{E}(U)\) for all open subschemes \(U \subseteq X\) together with exact restriction functors \(\widetilde{E}(U) \to \widetilde{E}(V)\) for \(V \subseteq U\) satisfying the usual compatibilities. A triangulated subpresheaf \(\widetilde{F}\) of \(\widetilde{E}\) is a collection of triangulated subcategories \(\widetilde{F}(U) \subseteq \widetilde{E}(U)\) compatible with restriction.

A semi-orthogonal decomposition \(\widetilde{E} = (\widetilde{E}_i | i \in I)\) is a list of triangulated subpresheaves \((\widetilde{E}_i)_{i \in I}\) of \(\widetilde{E}\) indexed by a totally ordered set \(I\) such that for each open \(U \subseteq X\) we have a semi-orthogonal decomposition \(\widetilde{E}(U) = (\widetilde{E}_i(U) | i \in I)\).

If \(X\) is noetherian then we write \(\widetilde{D}_X\) for the presheaf of triangulated categories \(U \mapsto \mathcal{D}(U)\) on \(X\). For a quasi-coherent sheaf of noetherian algebras \(\mathcal{A}\) on \(X\) we similarly put \(\widetilde{D}_{\mathcal{A}}(U) = \mathcal{D}(\mathcal{A} \mid U)\).

Let \(G\) be a reductive group acting on a \(k\)-scheme \(X\) such that a “good quotient” \(\pi : X \to X/G\) exists (see §3.3 below). Then we define a presheaf of triangulated categories \(\mathcal{D}_{X/G}\) on \(X/G\) as follows: if \(U \subseteq X/G\) is open then we put \(\mathcal{D}_{X/G}(U) = \mathcal{D}(U \times_{X/G} X/G)\).

**Theorem 1.1.2.** Let \(G\) be a reductive group acting on a smooth variety \(X\) such that a good quotient \(\pi : X \to X/G\) exists and put \(\mathcal{D} = \mathcal{D}_{X/G}\). There exist one-parameter subgroups \(\lambda_i : G_m \to G\) of \(G\), open subgroups \(H^{\lambda_i}\) of \(G^{\lambda_i}\), and finite dimensional \(H^{\lambda_i}\)-representations \(U_i\), such that \(\mathcal{D} = \langle \ldots, \mathcal{D}_{-2}, \mathcal{D}_{-1}, \mathcal{D}_0 \rangle\) with \(\mathcal{D}_i \cong \mathcal{D}_{\Lambda_i}\) for sheaves of \(\mathcal{O}_{X/G}^{\lambda_i}\)-algebras (viewed as \(\mathcal{O}_{X/G}\)-algebras) defined by \(\Lambda_i \cong (\text{End}(U_i) \otimes_k \pi_* \mathcal{O}_{X^{\lambda_i}})^{H^{\lambda_i}}\). The restrictions of \(\Lambda_i\) to affine opens have finite global dimension.

In this theorem the notation \((-)^{\lambda_i}\) was used for the fixed points under \(\lambda_i\) (see §3.3 below). Note that \(G^{\lambda_i}\) is a reductive subgroup of \(G\) (see §3.6) acting on \(X^{\lambda_i}\).

Theorem 1.1.2 applies in particular to GIT stack quotients of the form \(X^{ss}/G\) where \(X\) is a smooth projective variety over an affine variety equipped with an ample linearization. In that way Theorem 1.1.2 complements [HL15, Theorem 2.10] (and similar results in [BFK, DSH]) which constructs a semi-orthogonal decomposition of \(\mathcal{D}(X/G)\) in which one of the parts is \(\mathcal{D}(X^{ss}/G)\).

1. **The linear case.** The proof of Theorem 1.1.2 will be reduced ultimately to the case that \(G\) is connected and \(X\) is a representation. In this section we give a more precise description of the semi-orthogonal decomposition in this case.

We first need to introduce more notation. Let \(T \subseteq B\) be a maximal torus and a Borel subgroup in \(G\). Let \(X(T)\) and \(Y(T) = X(T)^{\vee}\) be respectively the character group of \(T\) and the group of one-parameter subgroups of \(T\). Let the roots of \(B\) be the negative roots and let \(X(T)^{+}\), \(Y(T)^{+}\) be the (anti-)dominant cones in \(X(T)\) and \(Y(T)\). Let \(\beta \in X(T)_{\mathbb{R}}\) be half the sum of the positive roots.

Let \(W\) be a finite dimensional \(G\)-representation of dimension \(d\) such that \(X = W^{\vee}\) and let \(R = k[X] = \text{Sym}(W)\). Let \((\beta_i)_{i=1}^d \in X(T)\) be the \(T\)-weights of \(W\). For

---

*Variety here means an integral separated noetherian \(k\)-scheme.*
λ ∈ Y(T)− define the following subsets of X(T)R

\[ \Sigma_\lambda = \left\{ \sum_i a_i \beta_i \mid a_i \in \mathbb{Z}, \langle \lambda, \beta_i \rangle = 0 \right\}, \quad \Sigma := \Sigma_0. \]

We denote Σ_0 = \text{relint}\Sigma_\lambda = \{\sum_i a_i \beta_i \mid a_i \in \mathbb{Z}, \langle \lambda, \beta_i \rangle = 0\}. With W_\lambda we denote the coinvariants for the action of \lambda (i.e. the quotient space of \mathcal{W} obtained by dividing out the weight vectors \omega_i such that \langle \lambda, \beta_i \rangle \neq 0). We further denote (see also \[\text{above} below):

\[ G^{\lambda,+} = \{ g \in G \mid \lim_{t \to 0} \lambda(t)g\lambda(t)^{-1} \text{ exists} \}, \]

(Note that G^\lambda = G^{\lambda,+}/\text{rad} G^{\lambda,+} is the reductive Levi factor of G^{\lambda,+} containing T.) Let \mathcal{W} = N(T)/T be the Weyl group of G, and let W_{G^\lambda} \subset \mathcal{W} be the Weyl group of G^\lambda. We write \rho_\lambda \in X(T)R for half the sum the positive roots of G^\lambda and X(T)^\lambda for the G^\lambda-dominant weights inside X(T). For \chi \in X(T)^\lambda we write V_{G^\lambda}(\chi) = \text{Ind}_{G^\lambda \cap B}^G \chi. Le V_{G^\lambda}(\lambda) is the irreducible G^\lambda-representation with highest weight \chi (or sometimes also a G^{\lambda,+}-representation with the unipotent radical acting trivially). Note that G^\lambda acts on W_\lambda (when we consider it as G^{\lambda,+} representation we let \text{rad} G^{\lambda,+} act trivially). For a W_{G^\lambda}-invariant \nu \in X(T)_R we put \mathcal{L}_{r,\lambda,\nu} = X(T)^\lambda \cap (\nu - \rho_\lambda + r \Sigma_f^0), \mathcal{U}_{r,\lambda,\nu} = \bigoplus_{\mu \in \mathcal{L}_{r,\lambda,\nu}} V_{G^\lambda}(\mu), A_{r,\lambda,\nu} = (\text{End}(U_{r,\lambda,\nu}) \otimes_k \text{Sym}(W_\lambda))^G.

\textbf{Proposition 1.2.1.} \[\text{[SVdB17a Theorem 1.4.1]}\] Assume r ≥ 1. Then one has gl \text{dim} A_{r,\lambda,\nu} < \infty.

\textbf{Proof.} As \nu is W_{G^\lambda}-invariant, this follows from \[\text{[SVdB17a Theorem 1.4.1]}\] in the case \Sigma_f^0 = \Sigma_f. Let \Gamma = -\rho + \{\sum_i a_i \beta_i \mid a_i \leq 0\}, \Gamma^0 = \text{relint}\Gamma. It is easy to modify the proof to hold also if \Sigma_f^0 \subseteq \Sigma_f. To replace \Sigma in \[\text{[SVdB17a Theorem 1.4.1]}\] with \Sigma^0 one only needs to show that Hom(P_\mathcal{E}, P_\lambda) = 0 if \chi \not\in \Gamma^0, and this follows by the same proof as \[\text{[SVdB17a Lemma 11.3.1]}\]. To replace \Sigma_f^0 by r \Sigma_f^0 is also easy. \[\square\]

We say that x ∈ X is T-stable if x has finite stabilizer and closed T-orbit. In the case X = Spec \mathcal{W} the existence of a T-stable point is equivalent to the cone spanned by the weights (\beta_i)_i of \mathcal{W} being equal to X(T)_R.

\textbf{Proposition 1.2.2.} Let \mathcal{D} = \mathcal{D}(X/G) and assume that X has a T-stable point. Then there exist \rho_i ≥ 1, \lambda_i ∈ Y(T)^- and W_{G^\lambda_i}-invariant \nu_i ∈ X(T)_R such that \mathcal{D} = (\ldots, \mathcal{D}_{-2}, \mathcal{D}_{-1}, \mathcal{D}_0), \mathcal{D}_{-i} \cong \mathcal{D}(A_{r_i, \lambda_i, \nu_i}), is a semi-orthogonal decomposition of \mathcal{D}. Moreover we may assume \mathcal{D}_0 \cong \mathcal{D}(A_{1,0,0}).

\textbf{Remark 1.2.3.} The reader will note that (under suitable genericity conditions) A_{1,0,0} is the non-commutative resolution of X/G constructed in \[\text{[SVdB17a Cor. 1.5.2]}\].

\textbf{Remark 1.2.4.} In Proposition \[\text{[1.2.2]}\] we assume that X has a T-stable point. This hypothesis is not very restrictive in view of \[\text{[above]}\] below. Roughly speaking if X does not have a T-stable point then one may easily obtain a semi-orthogonal decomposition of \mathcal{D}(X/G) involving a set of \mathcal{D}(X'/G') such that X' has a T'-stable point for T' a maximal torus of G'.
1.3. **Refined decompositions.** The semi-orthogonal decompositions in Theorem 1.1.2 and Proposition 1.2.1 are not optimal. At the cost of extra technicalities one may decompose the parts $D_{-i}$ further by essentially repeating the procedure which is used to obtain the decomposition of $D$ itself. This leads to the natural problem to produce a decomposition which cannot be refined further in the sense that the parts admit no non-trivial semi-orthogonal decompositions. The latter is in particular the case if the parts are all of the form $D(\Lambda)$ where $\Lambda$ is a (possibly twisted) non-commutative crepant resolution (NCCR) of its center [Leu12, VdB04, Wem16]. In §8 we will discuss this problem in the case that $W$ is “quasi-symmetric”, i.e. the sum of the weights of $W$ on each line through the origin is zero.

It is shown in [ŠVdB17a, §1.6] that in this case, by replacing $\Sigma$ by a polygon of roughly half the size, one obtains smaller non-commutative resolutions for $X//G$.

Under favourable conditions one may even obtain NCCRs.

Likewise in §8 we will show that if $W$ is quasi-symmetric one may obtain corresponding more refined semi-orthogonal decomposition of $D(X/G)$ which again under favorable conditions consists entirely of (twisted) NCCR parts. So they cannot be refined further. See §8 in particular Corollary 8.5. As an example we mention the following explicit result which refines our construction of NCCRs for odd Pfaffians in [ŠVdB17a].

**Proposition 1.1** (see Proposition 8.9). Let $2n < h$, $W = V^h$, where $V$ is $2n$-dimensional vector space equipped with a non-degenerate skew-symmetric bilinear form, $G = \text{Sp}_{2n}(k)$, and let $Y_{2n,h} = W//G$ be the variety of skew-symmetric $h \times h$-matrices of rank $\leq 2n$. We denote by $\Lambda_j$ the NCCR of $Y_{2j,h}$ given by [ŠVdB17a Proposition 6.1.2] (by convention we put $\Lambda_0 = k$). If $h$ is odd then $D(X/G)$ has a semi-orthogonal decomposition $\langle \ldots, D_{-2}, D_{-1}, D_0 \rangle$ with $D_0 \cong D(\Lambda_n)$ such that each $D_{-i}$ for $i > 0$ is of the form $D(\Lambda_j)$ for some $j < n$.

Other examples we discuss are quasi-symmetric toric representations, representations of $\text{SL}_2$ and the analogue of Proposition 1.1 for ordinary determinantal varieties.

2. **Acknowledgement**

The second author thanks Jørgen Vold Rennemo and Ed Segal for interesting discussions regarding this paper. The authors thank Agnieszka Bodzenta and Alexey Bondal for their interest in this work and for useful comments on the first version of this paper.

3. **Preliminaries**

3.1. **Strongly étale morphisms.** Let $G$ be reductive group. If $G$ acts on an affine $k$-scheme $X$ then we put $X//G = \text{Spec } k[X]^G$. This is a special case of a “good quotient” (see §3.3 below). Let $f : X \to Y$ be a $G$-equivariant morphism between affine $G$-schemes. Following [Lun73, MPK94 App. D] we say that $f$ is strongly étale if $X//G \to Y//G$ is étale and the induced morphism $X \to Y \times_{Y//G} X//G$ is an

---

2The indecomposability of (twisted) NCCR’s seems to be well known to experts. It may be easily proved in a similar way as [ŠVdB17b Lemma A.4].

3See also [HLS16] where, again under appropriate conditions, it is shown that these NCCRs are of geometric origin in the sense that they are derived equivalent to suitable $X^{ss}//G$. 

Lemma 3.1.1. Assume that \( f : X \to Y \) is a strongly étale \( G \)-equivariant morphism of affine schemes and let \( H \) be a reductive subgroup of \( G \). Then \( f \) is strongly étale as \( H \)-equivariant morphism.

Proof. From the fact that \( H \) is reductive we easily obtain
\[
k[X] = (k[Y] \otimes k[Y]|_H k[X]^G)^H = k[Y]^H \otimes k[Y]|_H k[X]^G.
\]
Thus
\[
k[Y] \otimes k[Y]|_H k[X] = k[Y]^H \otimes k[Y]|_H k[X]^G = k[Y] \otimes k[Y]|_H k[X] = k[X].
\]

3.2. The Białynicki-Birula decomposition in the affine case. We use [Dri13] as a reference for some facts about the Białynicki-Birula decomposition [BB73]. Let \( R \) be a commutative \( k \)-algebra equipped with a rational \( G_m \)-action \( \lambda : G_m \to \text{Aut}_k(R) \). This \( G_m \)-action induces a grading on \( R = \bigoplus_n R_n \). We define \( R_\lambda := R/I. \ R_\lambda^\pm := R/I^\pm. \) Note
\[
(R_\lambda^\pm)_0 = R^\lambda.
\]
If \( X = \text{Spec} R \) then we also write \( X^\lambda = \text{Spec} R^\lambda, \ X^\lambda^\pm = \text{Spec} R^\lambda^\pm. \) It follows from [Dri13] §1.3.4 that \( X^\lambda \) is the subscheme of fixed points of \( X \) and \( X^\lambda^+, X^\lambda^- \) are respectively the attractor and repeller subschemes of \( X \). According to [Dri13] Prop 1.4.20], \( X^\lambda, X^\lambda^\pm \) are smooth if this is the case for \( X \).

Lemma 3.2.1. Assume that \( f : X \to Y \) is a strongly étale \( G_m \)-equivariant morphism of affine schemes, with the action denoted by \( \lambda \). Then
\[
X^\lambda = X \times_Y Y^\lambda
\]
\[
X^\lambda^+ = X \times_Y Y^\lambda^+
\]
\[
X^\lambda^- = X \times_Y Y^\lambda^-.
\]

Proof. We have
\[
k[X] = k[Y] \otimes k[Y]|_\lambda k[X]^G
\]
since \( f \) is a strongly étale \( G_m \)-equivariant morphism, and this isomorphism is clearly compatible with the grading on both sides. Thus
\[
k[X]_n = k[Y]_n \otimes k[Y]|_\lambda k[X]_0.
\]
The lemma now follows easily from the definitions.

3.3. The Białynicki-Birula decomposition when there is a good quotient. We use the following definition from [Bri] (see the discussion after Prop. 1.29 in loc. cit.).

Definition 3.3.1. Let \( G \) be a reductive group and let \( \pi : X \to Y \) be a \( G \)-equivariant morphism of \( k \)-schemes. Then \( \pi \) is a good quotient if the following holds
\[
\begin{align*}
(1) & \quad \pi \text{ is affine,} \\
(2) & \quad \mathcal{O}_Y = (\pi_* \mathcal{O}_X)^G.
\end{align*}
\]
It is easy to see that a good quotient is unique, if it exists. Therefore following tradition we will usually write $Y = X//G$. We have already used this notation in the case that $X$ is affine. Note the following

**Lemma 3.3.2.** Assume that $G$ is a reductive group acting on a $k$-scheme $X$ such that $X//G$ exists. Let $H$ be a reductive subgroup of $G$. Then $X//H$ also exists.

**Proof.** Let $\pi : X \to X//G$ be the good quotient. It is easy to verify that $X//H = \text{Spec}(\pi_* \mathcal{O}_X)^H$. \hfill $\square$

Assume now that $X$ is a $k$-scheme on which $G_m$ acts via $\lambda : G_m \to \text{Aut}(X)$. Assume that a good quotient $\pi : X \to X//G_m$ exists. If $U \subset X//G_m$ is an open affine subvariety then we may define closed subvarieties $\pi^{-1}(U)^\lambda$, $\pi^{-1}(U)^\lambda,\pm$ of $\pi^{-1}(U)$ as in §3.2 and according to Lemma 3.2.1 these are compatible with restrictions for $U' \subset U$. Hence we may glue these closed subvarieties to obtain $X^\lambda$, $X^{\lambda,\pm} \subset X$. One may verify that $X^\lambda$, $X^{\lambda,\pm}$ are still the fixed points and the attractor/repeller subschemes for $\lambda$.

### 3.4. Good quotients and geometric invariant theory

One way to obtain good quotients is via the machinery of geometric invariant theory [MFK94]. Let $G$ be a reductive group and let $X$ be a $G$-equivariant $k$-scheme which is projective over an affine scheme, equipped with a $G$-equivariant ample line bundle $\mathcal{M}$. If $f \in \Gamma(X, \mathcal{M}^{\otimes n})^G$, $n > 0$, then $X_f := \{f \neq 0\} \subset X$ is affine and $G$-equivariant. The semi-stable locus in $X$ is defined as $X^{ss} = \bigcup_f X_f$. This is an open subvariety of $X$ which has a good quotient $X^{ss}//G$ which may be obtained by gluing $X_f//G = \text{Spec} k[X_f]^G$ for varying $f$. Another way to obtain $X^{ss}//G$ is as follows: let $\Gamma^*_s(X) = \bigoplus_n \Gamma(X, \mathcal{M}^{\otimes n})^G$. Then $X^{ss}//G = \text{Proj} \Gamma^*_s(X)^G$.

The following result, whose proof we omit since we do not use it, gives an alternative description of $X^{ss,\lambda}$, $X^{ss,\lambda,\pm}$ in the GIT setting.

**Proposition 3.4.1.** Let $G$ be a reductive group and let $X$ be a $G$-equivariant $k$-scheme which is projective over an affine scheme. Let $\mathcal{M} \in \text{Pic}(X)$ be a $G$-equivariant ample line bundle on $X$ and let $X^{ss} \subset X$ be the corresponding semi-stable locus.

Let $R = \Gamma^*_s(X)$ and let $\lambda$ be a one-parameter subgroup of $G$. Then $\lambda$ acts on $R$ in a way which is compatible with the grading and $X^{ss,\lambda}$, $X^{ss,\lambda,\pm}$ are the closed subschemes of $X^{ss}$ defined by the (graded) quotient rings $R^{\lambda}$, $R^{\lambda,\pm}$ of $R$ (see [3.2]).

### 3.5. Good quotients and local generation

Let $X/k$ be a quasi-compact, quasi-separated $G$-scheme for a reductive group $G/k$ such that a good quotient $\pi : X \to X//G$ exists. It is easy to see that then $X//G$ is quasi-compact and quasi-separated as well. Below we write $\pi_* : X//G \to X//G$ for the corresponding stack morphism. Note that both $\pi_*$ and $\pi_{**}$ are exact.

Below we use some notations and concepts related to derived categories which were introduced in [3.2]. We recall some properties of $D_{\text{Qch}}(X//G)$.

**Theorem 3.5.1.**

1. $D_{\text{Qch}}(X//G)$ is compactly generated.
2. An object in $D_{\text{Qch}}(X//G)$ is compact if and only if it is perfect. I.e. if and only if its image in $D(X)$ is perfect.
3. If $X$ is separated then $D_{\text{Qch}}(X//G) = D(\text{Qch}(X//G))$. 

For every affine open $U$ of $D$ say that the full subcategory of $\text{Definition 3.5.2}$. Proof. (1) follows from [HR17, Thm B]. It also follows from this result and the proof of [Nee92] Lemma 2.2 that every compact object is perfect. On the other hand it is easy to see that in this case every perfect object is compact. This proves (2). Finally (3) follows from [HNR, Thm 1.2]. □

For an open $U \subset X/G$ we write $\tilde{U} = U \times_{X/G} X \subset X$.

**Definition 3.5.2.** Let $(E_i)_{i \in I}$ be a collection of perfect objects in $D_{Qch}(X/G)$. We say that the full subcategory of $D_{Qch}(X/G)$, spanned by all objects $F$ such that for every affine open $U \subset X/G$ the object $F|U$ is in the smallest thick subcategory of $D_{Qch}(\tilde{U}/G)$ containing $(E_i|\tilde{U})_i$, is locally classically generated by $(E_i)_{i \in I}$.

Let us say that $F, G \in D_{Qch}(X/G)$ are locally isomorphic if there exists a covering $X/G = \bigcup_{j \in I} U_j$ such that $F|\tilde{U}_j \cong G|\tilde{U}_j$ for all $i$. It is convenient to call a subcategory of $D_{Qch}(X/G)$ locally closed if it is closed under local isomorphism.

**Lemma 3.5.3.** Let $(E_i)_{i \in I}$ be a collection of perfect objects in $D_{Qch}(X/G)$ and let $F \in \text{Perf}(X/G)$. Let $X/G = \bigcup_{j=1}^n U_j$ be a finite open affine covering of $X/G$. If for all $j$ one has that $F|\tilde{U}_j$ is in the smallest thick subcategory of $D_{Qch}(\tilde{U}_j/G)$ containing $(E_i|\tilde{U}_j)_i$ then $F$ is in the subcategory of $D_{Qch}(X/G)$ locally classically generated by $(E_i)_{i \in I}$.

Proof. Let $U \subset X/G$ be an affine open. We have to show that $F|\tilde{U}$ is in the smallest thick subcategory of $D_{Qch}(\tilde{U}/G)$ containing $(E_i|\tilde{U})_i$. By replacing $X/G$ by $U$ and refining the cover $U = \bigcup_{j \in I} U \cap U_j$ to an affine one we reduce to the case that $X/G$ is itself affine. In particular by Theorem 3.5.1 as affine schemes are separated, $D_{Qch}(X/G)$ is the derived category of $G$-equivariant $k[X]$-modules. The affine $U_j$ yield $G$-equivariant flat extensions $k[\tilde{U}_j]$ of $k[X]$.

Let $E$ be the smallest cocomplete triangulated subcategory of $D_{Qch}(X/G)$ containing $(E_i)_{i \in I}$ and similarly let $E_j$ be the smallest cocomplete triangulated subcategory of $D_{Qch}(U_j/G)$ containing $(E_i|\tilde{U}_j)_i$. By the Brown representability theorem [Nee96] Theorem 4.1 there is a unique distinguished triangle

$$F_0 \to F \to F_1 \to$$

where $F_0 \in E$ and $F_1 \in E^\perp$. Since $U_j$ is affine it is easy to see that $F_1|\tilde{U}_j \in E_j^\perp$. But by hypothesis $F|\tilde{U}_j \in E_j$ and thus $F_1|\tilde{U}_j = 0$. Since this is true for all $j$ we conclude $F_1 = 0$ and hence $F \in E$. Since $F$ is compact and $E$ is compactly generated by Theorem 3.5.1 the conclusion follows from [Nee92] Lemma 2.2. □

**Lemma 3.5.4.** The category $\text{Perf}(X/G)$ is locally classically generated by $(V \otimes_k O_X)_V$ where $V$ runs through the irreducible representations of $G$.

Proof. We may assume that $X$ is affine and then it is clear. □

It will be convenient to pick for every $E \in D_{Qch}(X/G)$ a $K$-injective resolution $E \to I_E$ and to define $\pi_{ss} \text{RHom}_{X/G}(E, F)$ as the complex of sheaves $U \to \text{Hom}_{D_{Qch}}(I_E|\tilde{U}, I_F|\tilde{U})^G$ on $X/G$. With this definition $\Lambda := \pi_{ss} \text{REnd}_{X/G}(E) := \pi_{ss} \text{RHom}_{X/G}(E, E)$ is a sheaf of DG-algebras on $X/G$ and $\pi_{ss} \text{RHom}_{X/G}(E, F)$ is a sheaf of right $\Lambda$-DG-modules.

**Remark 3.5.5.** Note that if $U \subset X/G$ is affine then $\Lambda|U$ is the sheaf of DG-algebras associated to the DG-algebra $\text{REnd}_{\tilde{U}/G}(E)$. We will use this routinely below.
Lemma 3.5.6. Assume that \( \mathcal{D} \subset D_{Qch}(X/G) \) is locally classically generated by the perfect complex \( E \) and let \( \Lambda = \pi_* \mathcal{R}\text{End}_{X/G}(E) \) be the sheaf of DG-algebras on \( X/G \) as defined above. The functors
\[
\mathcal{D} \to \text{Perf}(\Lambda) : F \mapsto \pi_* \mathcal{R}\text{Hom}_{X/G}(E, F),
\]
\[
\text{Perf}(\Lambda) \to \mathcal{D} : H \mapsto H \otimes_{\Lambda} E,
\]
are well-defined (the second functor is computed starting from a \( K \)-flat resolution\(^4\) of \( H \)) and yield inverse equivalences between \( \mathcal{D} \) and \( \text{Perf}(\Lambda) \).

Proof. The two functors are adjoint functors between \( D_{Qch}(X/G) \) and \( D(\Lambda) \). The fact that they define functors between \( \mathcal{D} \) and \( \text{Perf}(\Lambda) \) can be checked locally. The fact that the unit and counit are invertible can also be checked locally. \( \Box \)

Lemma 3.5.7. Assume that \( X \) is a smooth \( k \)-scheme. Let \( E \in D(X/G) \). If \( \Lambda = \pi_* \mathcal{R}\text{End}_{X/G}(E) \) is a sheaf of algebras of finite global dimension when restricted to affine opens in \( X/G \) then the induced fully faithful functor (see Lemma 3.5.6)
\[
I : \mathcal{D}(\Lambda) \to \mathcal{D}(X/G) : H \mapsto H \otimes_{\Lambda} E
\]
is admissible (i.e. it has a left and a right adjoint).

Proof. The right adjoint to \( I \) is given \( \pi_* \mathcal{R}\text{Hom}_{X/G}(E, -) \). To construct the left adjoint note that there is a duality \( \mathcal{D}(\Lambda)^{\vee} \to \mathcal{D}(\Lambda) \) given by \(( - )^{\vee} := \mathcal{R}\text{Hom}_{\Lambda}(-, \Lambda) \). One checks that the left adjoint to \( I \) is given by \( \pi_* \mathcal{R}\text{Hom}_{X/G}(-, E)^{\vee} \). \( \Box \)

The following result shows that semi-orthogonal decompositions can be constructed locally.

Proposition 3.5.8. Let \( I \) be a totally ordered set. Assume \( \mathcal{D} \subset \text{Perf}(X/G) \) is locally classically generated by a collection of locally closed subcategories \( \mathcal{D}_i \subset \text{Perf}(X/G) \). Assume \( \pi_* \mathcal{R}\text{Hom}_{X/G}(\mathcal{D}_i, \mathcal{D}_j) = 0 \) for \( i > j \). Then \( \mathcal{D} \) is generated by \( (\mathcal{D}_i) \), and in particular we have a semi-orthogonal decomposition \( \mathcal{D} = \langle \mathcal{D}_i \mid i \in I \rangle \).

Proof. It is clear that we may first reduce to the case that \( I \) finite and then to \( |I| = 2 \). Hence we assume \( I = \{1, 2\} \). In the same vein we may reduce to the case that the \( \mathcal{D}_i \) are locally classically generated by single perfect complexes \( (E_i)_{i=1,2} \).

Put \( \Lambda_i = \pi_* \mathcal{R}\text{End}_{X/G}(E_i) \).

Let \( F \in \mathcal{D} \). Then for every affine \( U \subset X/G, F|\hat{U} \) is in the thick subcategory of \( \text{Perf}(\hat{U}/G) \) generated by \( E_1|\hat{U}, E_2|\hat{U} \) (by the definition of local classical generation, cfr. Definition 3.5.2).

Put \( F_2 = \pi_* \mathcal{R}\text{Hom}_{X/G}(E_2, F) \otimes_{\Lambda_2} E_2 \). Since \( \mathcal{R}\text{Hom}_{X/G}(E_2, E_1) = 0 \) we deduce (checking locally) that \( \pi_* \mathcal{R}\text{Hom}_{X/G}(E_2, F) \in \text{Perf}(\Lambda_2) \) and hence that \( F_2 \in \mathcal{D}_2 \). Put \( F_1 = \text{cone}(F_2 \to F) \). Then we obtain \( \pi_* \mathcal{R}\text{Hom}_{X/G}(E_2, F_1) = 0 \) (again checking locally). Let \( C \) be the cone of \( \pi_* \mathcal{R}\text{Hom}_{X/G}(E_1, F_1) \otimes_{\Lambda_1} E_1 \to F_1 \). Since \( \pi_* \mathcal{R}\text{Hom}_{X/G}(E_i, C) = 0 \) for \( i = 1, 2 \) we conclude \( C = 0 \) and thus \( F_1 = \pi_* \mathcal{R}\text{Hom}_{X/G}(E_1, F_1) \otimes_{\Lambda_1} E_1 \). It follows that if \( U \subset X/G \) is affine then \( F_1|\hat{U} \)

\(^4\)Such a \( K \)-flat resolution is constructed in the same way as for DG-algebras (see [Ke93, Theorem 3.1.1b]). One starts from the observation that for every \( M \in D(\Lambda) \) there is a morphism \( \bigoplus_{i \in I} \mu_i(\Lambda|U_i) \to M \) with open immersions \( (j_i: U_i \to X/G)_{i \in I} \), which is an epimorphism on the level of cohomology.
is in the cocomplete subcategory of $D_{\text{Qcoh}}(X/G)$ generated by $E_1\bar{U}$. Since $E_1\bar{U}$, $F_1\bar{U}$ are compact we conclude by [Nee92] Lemma 2.2 that $F_1\bar{U}$ is in the thick subcategory of $\text{Perf}(U/G)$ generated by $E_1\bar{U}$. As this is true for all $U$ we obtain that $F_1 \in D_1$. Hence $D$ is generated by $D_1$, $D_2$.

3.6. The Bialynicki-Birula decomposition for reductive algebraic groups.

We recall the following.

**Proposition 3.6.1.** [Spr98] Proposition 8.4.5, Exercise 8.4.6(5), Theorem 13.4.2

Let $G$ be a connected reductive algebraic group and let $\lambda : G_m \to G$ be a one-parameter subgroup of $G$. Then $G^\lambda$, $G^{\lambda, \pm}$ are connected subgroups of $G$. Moreover the $G^{\lambda, \pm}$ are parabolic subgroups of $G$ and $G^\lambda$ is the Levi-subgroup of $G^{\lambda, \pm}$.

We recall the following.

**Lemma 3.6.2.** Let $G$ be a connected reductive algebraic group with $T \subset B \subset G$ being a maximal torus and a Borel subgroup of $G$. Let $\lambda \in Y(T)^-$ and $\chi \in X(T)^+$ and let $V(\chi)$ be the irreducible $G$-representation with highest weight $\chi$. Then $\text{Res}_{G^\lambda}^G V(\chi) = V(G^\lambda(\chi)) \oplus \bigoplus V(G^\lambda(\mu_i))$ with $\langle \lambda, \mu_i \rangle > \langle \lambda, \chi \rangle$.

**Proof.** This is similar to the proof that $\chi$ occurs with multiplicity one among the weights of $V(\chi)$ [Jan87] Proposition 2.4]. All the weights $\mu$ of $V(\chi)$ satisfy $\langle \lambda, \mu \rangle \geq \langle \lambda, \chi \rangle$ as $\lambda \in Y(T)^-$. Hence we have a decomposition $V(\chi) = V(\chi)^\lambda \oplus V(\chi)^+$ where $V(\chi)^+$ is the span of the weight vectors with weights $\mu$ such that $\langle \lambda, \mu \rangle > \langle \lambda, \chi \rangle$. It is clear that this is a decomposition as $G^\lambda$-modules. If $V(\chi)^\lambda$ is decomposable then it is easy to see that its indecomposable summands generate distinct $G$-subrepresentations of $V(\chi)$ which is impossible.

Since $V(\chi)^\lambda$ contains the weight vector with weight $\chi$ we must have $V(\chi)^\lambda = V(G^\lambda(\chi))$. \hfill \Box

3.7. The $G/G_e$-action on weights. Let $G$ be a reductive group such that $T \subset B \subset G_e$ are respectively a maximal torus and a Borel subgroup of $G_e$.

Let $g \in G$ and $\sigma_g = g \cdot \cdot g^{-1} \in \text{Aut}(G_e)$. Then $\sigma_g(T) \subset \sigma_g(B)$ are respectively a maximal torus and a Borel subgroup of $G_e$. Thus there exists $g_0 \in G_e$ such that $g_0 \sigma_g(T)g_0^{-1} = T$, $g_0 \sigma_g(B)g_0^{-1} = B$.

In the sequel if $\bar{g} \in G/G_e$ then we write $\sigma_{\bar{g}} \in \text{Aut}(G_e)$ for $g_0 g$ where $g_0 g$ is an element of the coset $\bar{g}$ such that $g_0 g$ preserves $(T, B)$. Since $g_0$ is unique up to multiplication by an element of $T$, $\sigma_{\bar{g}}$ is well defined up to conjugation by an element of $T$. Since $\sigma_{\bar{g}}$ preserves $(T, B)$ it yields a well defined action on $X(T)$ via $\chi \mapsto \chi \circ \sigma_{\bar{g}}$ which preserves $X(T)^+$. We will write $\bar{g}(\chi)$ for $\chi \circ \sigma_{\bar{g}}^{-1}$. There is also an action of $G/G_e$ on $Y(T)$ given by $\lambda \mapsto \sigma_{\bar{g}} \circ \lambda$. Finally we have

$\langle \lambda, \chi \circ \sigma_{\bar{g}} \rangle = \langle \sigma_{\bar{g}} \circ \lambda, \chi \rangle$.

If $\lambda \in Y(T)$ then we will write $(G/G_e)^\lambda \subset G/G_e$ for the stabilizer of $\lambda$ under the $G/G_e$-action on $Y(T)$. Let $\bar{G}^\lambda$ be the inverse image of $(G/G_e)^\lambda$ in $G$. There is an obvious inclusion $(G/G_e)^\lambda \subset G_e G^\lambda/G_e = G^\lambda/G_e^\lambda$. We will write $H^\lambda$ for the (open) subgroup of $G^\lambda$ such that $G^\lambda_e \subset H^\lambda$ and $H^\lambda / G_e^\lambda = (G/G_e)^\lambda$. So $G^\lambda / G_e = H^\lambda / G_e^\lambda$.

For $\chi \in X(T)^+$ we put $V_G(\chi) := \text{Ind}_{G_e}^G \chi$. Note that if $G$ is not connected then $V_G(\chi)$ will usually not be simple. We have

$$\text{Res}_{G_e}^G V_G(\chi) = \bigoplus_{\bar{g} \in G/G_e} \sigma_{\bar{g}} V_G(\chi)$$
and
\[(3.3) \quad \sigma_g V_{G_e}(\chi) \cong V_{G_e}(\chi \circ \sigma_g).\]

4. Reduction settings

Now we introduce our main technical tool to obtain semi-orthogonal decompositions of \(D(X/G)\). In §4.1 we introduce the concept of a \emph{reduction setting}. In §4.2 we give our main technical result about such reduction settings. Subsequent sections are concerned with the construction of reduction settings. Since the definitions and results are quite technical and not so easy to motivate, the reader is advised to skim this section on first reading and come back to it afterwards.

4.1. Definition. Let \(G\) be a reductive group such that \(T \subset B \subset G_e\) are respectively a maximal torus and a Borel subgroup of \(G_e\).

Below we consider the situation where \(G\) acts on a variety \(X\). In that case we also put for \(\chi \in X(T)^+\)
\[P_\chi = V_G(\chi) \otimes_k O_X \in \text{coh}(X/G).\]
To indicate context we may also write \(P_{G,\chi}, P_{G,X,\chi},\) etc.

If \(\mathcal{L} \subset X(T)^+\) then we put \(P_\mathcal{L} = \bigoplus_{\chi \in \mathcal{L}} P_\chi\). We make the following definition (using some notation introduced in §4.1).

Definition 4.1.1. A \emph{reduction setting} is a tuple \((G, B, T, X, \mathcal{L}, \chi, \lambda)\) with the following properties:

1. \(G\) is a reductive group and \(T \subset B \subset G_e\) are respectively a maximal torus and a Borel subgroup of \(G\).
2. \(\chi \in X(T)^+\).
3. \(\lambda \in Y(T)^-\).
4. \(\mathcal{L}\) is a finite subset of \(X(T)^+\) invariant under \(G/G_e\).
5. \(\forall \mu \in \mathcal{L} : \langle \lambda, \chi \rangle < \langle \lambda, \mu \rangle\).
6. \(X\) is a smooth \(G\)-equivariant \(k\)-scheme such that a good quotient \(\pi : X \to X/G\) exists (with associated stack morphism \(\pi_* : X/G \to X/\!\!/G\)).
7. (We will show in Lemma 4.1.2 below that (5) implies (4.1))

\[\pi_* \text{RHom}_{X/G} \left( P_{G,\mathcal{L}}, \text{RInd}_{G_e^\lambda_+}^G (V_{G_e^\lambda_+} (\chi) \otimes_k j_* O_{X^\lambda_+}) \right) = 0\]
where \(j\) is the inclusion \(X^\lambda_+ \subset X\). Consider the map

\[P_{G,X} = \text{RInd}_{G_e^\lambda_+}^G (V_{G_e^\lambda_+} (\chi) \otimes O_X) \to \text{RInd}_{G_e^\lambda_+}^G (V_{G_e^\lambda_+} (\chi) \otimes k j_* O_{X^\lambda_+})\]

obtained by applying \(\text{RInd}_{G_e^\lambda_+}^G (V_{G_e^\lambda_+} (\chi) \otimes -)\) to the obvious map \(O_X \to j_* O_{X^\lambda_+}\). Combining (4.2) with (4.1) we obtain from the axioms of triangulated categories a canonical map

\[\text{cone} \left( \pi_* \text{Hom}_{X/G} (P_{G,\mathcal{L}}, P_{G,X}) \otimes_{\pi_* \text{End}_{X/G} (P_{G,\mathcal{L}})} P_{G,\mathcal{L}} \to P_{G,X} \right) \] 
\[\to \text{RInd}_{G_e^\lambda_+}^G (V_{G_e^\lambda_+} (\chi) \otimes_k j_* O_{X^\lambda_+}).\]

We require that (4.3) is an isomorphism.

The following lemma is necessary to complete Definition 4.1.1.

Lemma 4.1.2. Assume that \(\mathcal{L}\) is as in Definition 4.1.1(5). Then (4.1) holds.
Proof. By using an affine covering of $X/G$ we may assume that $X$ is affine. By adjointness we have

$$R\text{Hom}_{X/G}(P_G, \mathcal{L}, R\text{Ind}^G_{G_\chi}(V_{G_\chi}(\chi) \otimes_k \mathcal{O}_{X^{\chi,+}}))$$

$$= \bigoplus_{\mu \in \mathcal{L}} \text{Hom}_{G_\chi}(\text{Res}_{G_\chi}^G \text{Ind}_{G_\chi}^G V_{G_\chi}(\mu), R\text{Ind}^G_{G_\chi}(V_{G_\chi}(\chi) \otimes_k k[X^{\chi,+}])).$$

By the $G/e$-invariance of $\mathcal{L}$, the simple summands of $(\text{Res}_{G_\chi}^G \text{Ind}_{G_\chi}^G V_{G_\chi}(\mu))_{\mu \in \mathcal{L}}$ are precisely the $(V_{G_\chi}(\mu))_{\mu \in \mathcal{L}}$ (see [3.2, 3.3]). In other words it suffices to prove that for every $\mu$ such that $\langle \lambda, \mu \rangle > \langle \lambda, \chi \rangle$ one has

$$\text{Hom}_{G_\chi}(V_{G_\chi}(\mu), R\text{Ind}^G_{G_\chi}(V_{G_\chi}(\chi) \otimes_k k[X^{\chi,+}])) = 0$$

Note

$$R\text{Ind}^G_{G_\chi}(V_{G_\chi}(\chi) \otimes k[X^{\chi,+}]) = R\text{Ind}^G_{G_\chi}(R\text{Ind}^G_B(\chi \otimes k[X^{\chi,+}]))

= R\text{Ind}^G_{G_\chi}(R\text{Ind}^G_B(\chi \otimes k[X^{\chi,+}]))

= R\text{Ind}^G_B(\chi \otimes k[X^{\chi,+}]).$$

Using the fact that the weights $\mu$ of $k[X^{\chi,+}]$ all satisfy $\langle \lambda, \mu \rangle \leq 0$ (see [3.2] we conclude as in the proof of [SVdB17a, Lemma 11.2.1] that the cohomology of $R\text{Ind}^G_B(\chi \otimes k[X^{\chi,+}])$ are direct sums of $V_{G_\chi}(\mu)$ with $\langle \lambda, \mu \rangle \leq \langle \lambda, \chi \rangle$. This finishes the proof. \hfill $\square$

4.2. Reduction settings and $R\text{Hom}$. The following technical result will be our main application of reduction settings.

**Proposition 4.2.1.** Assume that we have a reduction setting $(G, B, T, \chi, \lambda)$ and assume $\chi' \in X(T)^+$ is such that $\langle \lambda, \chi \rangle = \langle \lambda, \chi' \rangle$ and $\langle \lambda, \bar{g}(\chi') \rangle > \langle \lambda, \chi \rangle$ for all $\bar{g} \notin (G/e)^\lambda$. Let $i_\lambda : X^\lambda//H^\lambda \to X/G$ (see [3.2 for notation) be induced from $X^\lambda \to X$. It is clear that $i_\lambda$ is affine so $i_{\lambda, *} \text{ is exact.}$ Let $\pi_{s, \lambda}$ be the canonical map $X^{\lambda//H^\lambda} \to X^{\lambda//H^\lambda}$.

We have isomorphisms

$$\pi_{s, *} R\text{Hom}_{X/G}(R\text{Ind}^G_{G_\chi}(V_{G_\chi}(\chi) \otimes k \mathcal{O}_{X^{\chi,+}}), R\text{Ind}^G_{G_\chi}(V_{G_\chi}(\chi') \otimes k \mathcal{O}_{X^{\chi,+}}))$$

$$\cong i_{\lambda, s, \lambda, *} R\text{Hom}_{X^{\lambda//H^\lambda}}(P_{H^\lambda, X^{\lambda//H^\lambda}, X^{\lambda//H^\lambda}}, P_{H^\lambda, X^{\lambda//H^\lambda}, X^{\lambda//H^\lambda}}).$$

Moreover such isomorphisms are compatible with composition when applicable.

**Proof.** The right-hand side of (4.6) only has cohomology in degree zero. Hence it is sufficient to construct an isomorphism like (4.6) in the affine case, in a way which is compatible with restriction. So we now assume $X$ is affine. Using (4.1) (applied with $\chi$ replaced by $\chi'$) and (4.3) we may replace the first argument to $R\text{Hom}_{X/G}(-, -)$ in (4.6) by $B_{G, X}$ and as $P_{G, X} \cong \text{Ind}^G_{G_\chi} V_{G_\chi}(\chi) \otimes k[X]$, by adjointness we have to construct an isomorphism

$$R\text{Hom}_{G}(\text{Ind}^G_{G_\chi} V_{G_\chi}(\chi), R\text{Ind}^G_{G_\chi}(V_{G_\chi}(\chi') \otimes k[X^{\chi,+}]))$$

$$\cong \text{Hom}_{H^\lambda}(\text{Ind}^{H^\lambda}_{G_\chi} V_{G_\chi}(\chi), \text{Ind}^{H^\lambda}_{G_\chi} V_{G_\chi}(\chi') \otimes k[X^{\lambda//H^\lambda}]).$$
We do this next. We have

\[ (4.8) \quad \text{RHom}_G(\text{Ind}_{G_e}^G V_e(\chi), \text{RInd}_{G_e}^G (V_{G^2}(\chi') \otimes_k k[X^{\lambda,-}])) \]

\[ \cong \text{Hom}_{G_{\lambda}^+}(\text{Res}_{G_e}^{G_{\lambda}^+} (\text{Res}_{G_e}^G V_e(\chi)), V_{G^2}(\chi') \otimes_k k[X^{\lambda,-}]) \]

\[ \cong \bigoplus_{\tilde{g} \in G_{\lambda}^+ / G_e} \text{Hom}_{G_{\lambda}^+}((\text{Res}_{G_e}^{G_{\lambda}^+}) \circ \sigma_{\tilde{g}})(V_e(\chi), V_{G^2}(\chi') \otimes_k k[X^{\lambda,-}]) \]

where the last isomorphism follows by (3.3), the assumption \( \langle \lambda, \tilde{g}(\chi) \rangle > \lambda \chi \)' for all \( \tilde{g} \not\in (G / G_e)^\lambda = G^\lambda / G_e \) and the fact that all the weights \( \mu \) of \( k[X^{\lambda,-}] \) satisfy \( \langle \lambda, \mu \rangle \leq 0 \) by (3.2).

Assume \( \tilde{g} \in (G / G_e)^\lambda = G^\lambda / G_e \). By Lemma 3.6.2 as a \( G^\lambda \)-representation \( V_{G_e}(\chi \circ \sigma_{\tilde{g}}) \) is a direct sum of \( V_{G_E}(\chi \circ \sigma_{\tilde{g}}) \) and representations of the form \( V_{G^2}(\mu) \) with \( \langle \lambda, \mu \rangle > \lambda \chi \circ \sigma_{\tilde{g}} = \lambda \chi \). For similar reasons as above such \( V_{G^2}(\mu) \) cannot contribute to the right-hand side of (4.8) so that (4.8) is isomorphic to

\[ (4.9) \quad \bigoplus_{\tilde{g} \in G_{\lambda}^+ / G_e} \text{Hom}_{G_{\lambda}^+}((\sigma_{\tilde{g}} \circ \sigma_{\tilde{g}})(V_e(\chi), V_{G^2}(\chi') \otimes_k k[X^{\lambda,-}]) \]

\[ \cong \bigoplus_{\tilde{g} \in G_{\lambda}^+ / G_e} \text{Hom}_{G_{\lambda}^+}(V_{G^2}(\chi \circ \sigma_{\tilde{g}}), V_{G^2}(\chi') \otimes_k k[X^{\lambda,-}]) \]

where the second isomorphism follows again by considering \( \lambda \)-weights and (3.1). To finish the proof we recall that by definition \( \bar{G}^\lambda / G_e = H^\lambda / G_e \) and by (3.2)

\[ \bigoplus_{\tilde{g} \in H^\lambda / G_e} V_{G^2}(\chi \circ \sigma_{\tilde{g}}) = \text{Res}_{G_e}^{H_{G_e}} \text{Ind}_{G_e}^{G_{\lambda}^+} V_{G^2}(\chi). \]

It now suffice to apply the adjunction \( (\text{Res}_{G_e}^{H_{G_e}}, \text{Ind}_{G_e}^{G_{\lambda}^+}) \) to the right-hand side of (4.9) to obtain (4.7).

The compatibility with composition is a straightforward but tedious verification. \( \square \)

4.3. Reduction to unit components. We have the following convenient fact.

**Proposition 4.3.1.** Assume that \( G \) is a reductive group acting on a smooth variety \( X \). If \( (G_e, B, T, X, L, \chi, \lambda) \) is a reduction setting then so is \( (G, B, T, X, L, \chi, \lambda) \).

**Proof.** We only have to verify that (4.3) is an isomorphism and to do so we may assume that \( X \) is affine. We use Lemma 4.3.2 below. Assume that (4.10) holds for \( G = G_e \). Then applying the functor \( \text{Ind}_{G_e}^{G_{\lambda}^+} \) yields that it holds for \( G \). \( \square \)

**Lemma 4.3.2.** Assume that \( X \) is affine and assume that conditions (1.10) in Definition 4.1.1 hold. Let \( (P_{G, L}) \) be the smallest cocomplete subcategory of \( D_{Qch}(X / G) \) containing \( P_{G, L} \). Then (4.10) is an isomorphism if and only if

\[ (4.10) \quad P^* := \text{cone}(P_{G, X} \to \text{RInd}_{G_e}^{G_{\lambda}^+} (V_{G^2}(\chi) \otimes_k j_* j^* O_{X^{\lambda,-}}))[-1] \in \langle P_{G, L} \rangle. \]
Moreover in that case \( P^* \cong \text{Hom}_{X/G}(P_{G, \mathcal{L}}, P_{G, X}) \). In particular\(^5\) \( P^* \) may be represented by a complex in degrees \( \leq 0 \) whose entries are direct sums of \( P_{\mu, \mu} \)’s in \( \mathcal{L} \).

Proof. Since \( P_{G, \mathcal{L}} \) is compact by Theorem 4.4.2, the inclusion functor \( (P_{G, \mathcal{L}}) \hookrightarrow D_{\text{Qch}}(X/G) \) has a right adjoint by Brown representability [Nee96]. Moreover one checks that it is explicitly given by

\[
R = \text{RHom}_{X/G}(P_{G, \mathcal{L}}, -) \otimes_{\text{End}_{X/G}(P_{G, \mathcal{L}})} P_{G, \mathcal{L}}.
\]

So (4.3) is an isomorphism if and only if we have a distinguished triangle

\[
R(P_{G, X}) \to P_{G, X} \to \text{RInd}_{G_\mathcal{L}}^{G}(V_{G_\mathcal{L}}(\chi) \otimes_k \mathcal{O}_{X_{\mathcal{L}, +}}) \to \text{cone}(P_{G, X} \to \text{RInd}_{G_\mathcal{L}}^{G}(V_{G_\mathcal{L}}(\chi) \otimes_k \mathcal{O}_{X_{\mathcal{L}, +}}))[-1] \to
\]

where the first arrow is the counit. This in turn is true if and only if

\[
(P_{G, X}) \to \text{cone}(P_{G, X} \to \text{RInd}_{G_\mathcal{L}}^{G}(V_{G_\mathcal{L}}(\chi) \otimes_k \mathcal{O}_{X_{\mathcal{L}, +}}))[-1] \to
\]

is an isomorphism (and in that case \( P^* \cong R(P_{G, X}) \)). Clearly if (4.11) is an isomorphism then (4.10) holds. Conversely assume that (4.10) holds. Then (4.11) is a morphism in \( (P_{G, \mathcal{L}}) \). To test if it is an isomorphism we may apply \( \text{RHom}_{X/G}(P_{G, \mathcal{L}}, -) \). But then (4.11) becomes the identity by (4.1). Hence we are done. \( \square \)

4.4. Reduction to closed subschemes. We will create reduction settings first in the linear case (\( X \) being a representation) and then we will restrict them to closed subschemes. To do this will use the following theorem:

Theorem 4.4.1. Let \( G \) be a reductive group and let \( Y \subset X \) be a closed embedding of smooth \( G \)-varieties. If \( (G, B, T, X, \mathcal{L}, \chi, \lambda) \) is a reduction setting then so is \( (G, B, T, Y, \mathcal{L}, \chi, \lambda) \).

To prove this we may assume that \( X \) is affine. We first discuss a special case.

Lemma 4.4.2. Assume that \( (G, X, Y) \) are as in the statement of Theorem 4.4.1 but with \( X \) affine. Assume in addition that there is a \( G_m \)-action on \( X \) in a way which commutes with the \( G \)-action such that \( k[X] \) has only weights \( \geq 0 \) and \( k[Y] = k[X]^G \). Then the conclusion of Theorem 4.4.1 holds.

Proof. Assume that \( (G, B, T, X, \mathcal{L}, \chi, \lambda) \) is a reduction setting. If we replace the \( \text{End}_{X/G}(P_{G, \mathcal{L}}) \)-module \( \text{Hom}_{X/G}(P_{G, \mathcal{L}}, P_{G, X}) \) in (4.3) by its projective resolution we obtain a resolution

\[
(4.12) \quad P^*_X \cong \text{cone}(P_{G, X, X} \to \text{RInd}_{G_\mathcal{L}}^{G}(V_{G_\mathcal{L}}(\chi) \otimes_k k[X_{\mathcal{L}, +}]))[-1]
\]

as in Lemma 4.3.2 (we have switched to coordinate ring notation). Moreover we may assume that this resolution is \( G_m \)-equivariant. In addition since \( k[X_{\mathcal{L}, +}] \) is a quotient of \( k[X] \) it only has \( G_m \)-weights \( \geq 0 \) and this property is not affected by applying \( \text{RInd}_{G_\mathcal{L}}^{G}(V_{G_\mathcal{L}}(\chi) \otimes_k -) \). We conclude that as \( G \times G_m \)-equivariant \( k[X] \)-module \( P^*_X \) may be assumed to be a direct sum of \( P_{G, X, \mu} \otimes_k \sigma_n, n \geq 0 \) where \( \sigma_n \)

\( ^5 \)Replacing \( \text{Hom}_{X/G}(P_{G, \mathcal{L}}, P_{G, X}) \) with its projective resolution over \( \text{End}_{X/G}(P_{G, \mathcal{L}}) \).

\( ^6 \)Here we use that \( X \) is affine to identify global and local Hom’s.

\( ^7 \)If the \( G_m \)-action is denoted by \( \gamma \) then this condition may also be written as \( Y = X^{\gamma} \), \( X = X^{\gamma_{-}} \).
is the $G_m$-character $z \mapsto z^n$ and $\mu \in \mathcal{L}$. We then have
\[
(PG, x, \mu \otimes_k \sigma_n)^{G_m} = \begin{cases} 
PG, y, \mu & \text{if } n = 0 \\
0 & \text{if } n > 0 
\end{cases} 
\]
Taking $G_m$-invariants of \eqref{eq:1.12} we now get a similar resolution
\[
P^*_Y \cong \text{cone}(PG, Y, X \to \text{RInd}_{G^C_X}^{G_C}(V_G^C(\chi) \otimes_k k[X^{\lambda,+}])^{G_m}[-1]).
\]
Furthermore since the $G$ and $G_m$-action do not interfere with each other we have
\[
\text{RInd}_{G^C_X}^{G_C}(V_G^C(\chi) \otimes_k k[X^{\lambda,+}])^{G_m} = \text{RInd}_{G^C_X}^{G_C}(V_G^C(\chi) \otimes_k k[X^{\lambda,+}])^{G_m}
\]
and finally using the description of $k[X^{\lambda,+}]$ in \eqref{eq:3.2} we easily see that $k[X^{\lambda,+}]^{G_m} = k[Y^{\lambda,+}]$. We conclude that \eqref{eq:4.10} holds for $Y$. This finishes the proof by Lemma \ref{lem:4.3.2}.

We will now reduce the proof of Theorem \ref{thm:4.4.1} to the special case considered in Lemma \ref{lem:4.4.2} using the Luna slice theorem.

**Lemma 4.4.3.** Let $G$ be a linear algebraic group acting on an affine variety $X$ and let $P \in D_{\text{Qch}}(X/G)$. Assume that $P$ is zero in the neighborhood of any point with closed orbit, i.e. any $x \in X$ such that $Gx$ is closed has an open neighborhood $U_x$ such that $P|U_x = 0$. Then $P = 0$.

**Proof.** Put $U' = \bigcup_x U_x$ and $U = GU'$. Then $P|U = 0$ so it is sufficient to prove $U = X$. Assume this is not the case. Since $X - U$ is closed and $G$-invariant it contains a closed orbit (e.g. an orbit of minimal dimension). This is an obvious contradiction.

**Lemma 4.4.4.** If $(G, B, T, X, \mathcal{L}, \chi, \lambda)$ is such that the conditions \eqref{eq:1.12} from Definition \ref{def:4.3} hold, and such that $X$ is affine, then write $C_X$ for the cone of \eqref{eq:1.3}. If $\alpha : Z \to X$ is a strongly étale $G$-equivariant morphism then $\alpha^*(C_X) = C_Z$.

**Proof.** This ultimately boils down to $\alpha^*\mathcal{O}_{X^{\lambda,+}} = \mathcal{O}_{Z^{\lambda,+}}$ which is true thanks to Lemma \ref{lem:3.2.1}.

**Proof of Theorem 4.4.1** We assume that $(G, B, T, X, \mathcal{L}, \chi, \lambda)$ is a reduction setting and $X$ is affine. Thus $C_X = 0$ and we have to deduce from it $C_Y = 0$. According to Lemma \ref{lem:4.3.3} it suffices to do this in the neighborhood of any closed orbit. So let $GY$ be a closed orbit in $Y$ and let $N_Y$ be a $G_y$-invariant complement to $T_y(GY)$ in $T_y(Y)$. Then according to the Luna slice theorem \cite{Lun73} there is an affine $G_y$-invariant “slice” $y \in S \subset Y$ to the orbit of $y$ and strongly $G_y$-equivariant étale morphism $S \to N_Y$ which sends $y$ to $0$ such that the induced maps
\[
Y \xrightarrow{\beta} G \times_{G^C Y} S \xrightarrow{\beta} G \times_{G^C Y} N_Y
\]
are strongly étale. Then by Lemma \ref{lem:4.4.4} we have $\alpha^*(C_Y) = \beta^*(C_{G \times_{G^C Y} N_Y})$. Thus it is sufficient to prove that $C_{G \times_{G^C Y} N_Y} = 0$.

By assumption $GY$ is closed in $X$. Let $V$ be a $G_y$-invariant complement to $T_y(Y)$ in $T_y(X)$ and put $N_X := N_Y \oplus V$. Since $C_X = 0$, by the same reasoning as above we conclude that $C_{G \times_{G^C Y} N_X}$ is zero in a neighborhood of the zero section of $G \times_{G^C Y} N_X \to G/G^C Y$. However note that since $C_{G \times_{G^C Y} N_X}$ is natural, it is in particular equivariant for the scalar $G_m$-action on $N_X$. So in fact $C_{G \times_{G^C Y} N_X} = 0$.

Now let $G_m$ act on $N_X = N_Y \oplus V$ by acting trivially on $N_Y$ and with weight $-1$ on $V$. Then the inclusion $G \times_{G^C Y} N_Y \hookrightarrow G \times_{G^C Y} N_X$ falls under the setting considered
in Lemma \[4.3.2\] We conclude from this lemma that \( C_{G^+} \cdot N_Y = 0 \), finishing the proof. \( \square \)

4.5. Reduction settings in the connected linear case. We use the notation and conventions introduced in \[4.2\]. We need the twisted Weyl group action of \( \mathcal{W} \) on \( X(T) \): \( w \star \chi := w \chi + \rho - \bar{\rho} \). If \( \chi \in X(T) \) and there is some \( w \star \chi \) which is dominant then we write \( \chi^+ = w \star \chi \). Otherwise \( \chi^+ \) is undefined.

Proposition 4.5.1. Let \( G \) be a connected reductive group and assume \( B, T, \chi, \lambda, \mathcal{L} \) satisfy (4.14) in Definition 4.4.1. Let \( X = W^\vee \) where \( W \) is a \( G \)-representation with weights \( \beta_1, \ldots, \beta_d \). Assume \( (\chi + \beta_i + \cdots + \beta_{i-p})^+ \in \mathcal{L} \) for all \( i \neq \{i_1, \ldots, i_p\} \subseteq \{1, \ldots, d\} \), \( i_j \neq i_{j'} \) for \( j \neq j' \) such that \( (\chi + \beta_i + \cdots + \beta_{i-p})^+ \) is defined. Then \( (G, B, T, X, \mathcal{L}, \chi, \lambda) \) is a reduction setting.

Proof. We only have to verify (4.3). We denote by \( K_\lambda \) the subspace of \( W \) spanned by the weight vectors \( w_j \) such that \( \langle \lambda, \beta_j \rangle > 0 \). Note that \( \text{Spec} \text{Sym}(W/K_\lambda) \cong X^{\lambda+} \). In [SVdB17a] (11.3) we constructed a quasi-isomorphism

\[
C_{\lambda, \chi} \rightarrow \mathcal{R} \text{Ind}_{G^+, \lambda}(V_{G^*, \chi} \otimes_k [X^{\lambda+}]),
\]

where \( C_{\lambda, \chi} \) is a complex of the form

\[
C_{\lambda, \chi} \overset{\text{def}}{=} \bigoplus_{p \leq 0, q \geq 0} \mathcal{R}^q \text{Ind}_{G^+, \lambda}(\chi \otimes_k \wedge^p K_\lambda) \otimes_k [X][-p - q], d
\]

We showed that after forgetting the differential \( C_{\lambda, \chi} \) is a sum of \( G \)-equivariant projective modules of the form \( P_\mu \) where the \( \mu \) are among the weights

\[
(\chi + \beta_{i_1} + \beta_{i_2} + \cdots + \beta_{i_{p}})^+
\]

(with each such expression occurring at most once) where \( \{i_1, \ldots, i_{p}\} \subset \{1, \ldots, d\} \), \( i_j \neq i_{j'} \) for \( j \neq j' \) and \( \langle \lambda, \beta_i \rangle > 0 \) [SVdB17a] Lemma 11.2.1. Moreover there is a single copy of \( P_\chi \) which lives in degree zero. It is not explicitly stated in loc. cit. but it follows easily from the construction that this copy of \( P_\chi \) yields an inclusion \( P_\chi \rightarrow C_{\lambda, \chi} \) such that the composition \( P_\chi \rightarrow C_{\lambda, \chi} \rightarrow \mathcal{R} \text{Ind}_{G^+, \lambda}(V_{G^*, \chi} \otimes_k [X^{\lambda+}]) \) is the canonical morphism exhibited in (4.2).

Let \( C'_{\lambda, \chi} = C_{\lambda, \chi}/P_\chi \). Then by the fact that (4.13) is a quasi-isomorphism we have \( C'_{\lambda, \chi} \cong \text{cone}(P_\chi \rightarrow \mathcal{R} \text{Ind}_{G^+, \lambda}(V_{G^*, \chi} \otimes_k [X^{\lambda+}]))) \). Since by hypothesis the summands \( P_\mu \) of \( C'_{\lambda, \chi} \) are summands of \( P_\mathcal{L} \) we find that (4.10) holds and hence we are done by Lemma (4.3.2). \( \square \)

5. Partitioning \( X(T)^+ \)

5.1. Preliminaries. We assume we are in the setting of \[4.2\] In particular \( G \) is connected and acts on a representation \( X = W^\vee \). We now introduce some extra notation: We let \( \Phi \subset X(T) \) be the roots of \( G \). We write \( \Phi^- \) for the negative roots of \( G \) (the roots of \( B \)) and \( \Phi^+ \) for the positive roots. We choose a positive definite \( W \)-invariant quadratic form \( \langle - , - \rangle \) on \( X(T)^\mathbb{R} \). If \( \alpha \in \Phi \) then \( \alpha \in Y(T)^\mathbb{R} \) is the corresponding coroot defined by \( \langle \alpha, \chi \rangle = 2(\alpha, \chi)/(\alpha, \alpha) \) and the associated reflection on \( X(T)^\mathbb{R} \) is defined by \( s_\alpha(\chi) = \chi - (\alpha, \chi)\alpha \). We put \( \Phi^\vee = \{ \alpha \mid \alpha \in \Phi \} \).

We set \( \Phi_+ = \{ \alpha \in \Phi \mid \langle \lambda, \alpha \rangle = 0 \} \). We denote by \( \Phi_+^\chi = \Phi_+ \cap \Phi_\chi \) the set of positive roots of \( G^\chi \).
Let us recall a slightly extended version of [SVdB17a Corollary D.3.] with the same proof.

**Lemma 5.1.1.** Let \( \lambda \in Y(T)_{\mathbb{R}} \), \( w \in \mathcal{W} \), \( \chi \in X(T) \) such that \( w*\chi \) is dominant. Then \( \langle \lambda, w*\chi \rangle \leq \langle \lambda, \chi \rangle \) with equality if and only if \( w \in \mathcal{W}_G^\chi \).

**Proof.** When comparing with [SVdB17a Corollary D.3.] note that in loc. cit. the role of \( \lambda \) is played by \( y \), which is assumed to be dominant, rather than anti-dominant which is the case here. So the inequalities are reversed.

Since \( \chi^+ := w*\chi \) is dominant we have \( \chi^+ = s_{\alpha_1} \cdots s_{\alpha_l} \chi \) such that for each \( \chi_i := s_{\alpha_1} \cdots s_{\alpha_l} \chi \) the inequality \( \langle \alpha_{i+1}, \chi_i \rangle \leq -2 \) holds.

In loc. cit. it is shown that \( \langle \lambda, w*\chi \rangle \leq \langle \lambda, \chi \rangle \). Going through the proof we see that the only possibility for equality to occur is when \( \langle \lambda, \alpha_i \rangle = 0 \) for all \( i \). But then \( w' := s_{\alpha_1} \cdots s_{\alpha_l} \in \mathcal{W}_G^\chi \). Since \( \chi^+ \) is dominant it has trivial stabilizer for the \( * \)-action. Since \( (ww'^{-1})^* \chi^+ = \chi^+ \) we conclude \( w = w' \in \mathcal{W}_G^\chi \). \( \square \)

We will also need the following variant.

**Lemma 5.1.2.** Let \( \lambda \in Y(T)_{\mathbb{R}} \), \( w \in \mathcal{W} \), \( \chi \in X(T) \) such that \( w\chi \) is dominant. Then \( \langle \lambda, w\chi \rangle \leq \langle \lambda, \chi \rangle \) with equality if and only if \( w\chi \in \mathcal{W}_G^\chi \).

**Proof.** The proofs is along the same lines as the proof of Lemma 5.1.1 except that \( w\chi \) may have non-trivial stabilizer. This accounts for the slightly weaker conclusion. \( \square \)

We define

\[
T^+_\chi = \{ i \mid \langle \lambda, \beta_i \rangle > 0 \}, \quad T^0_\chi = \{ i \mid \langle \lambda, \beta_i \rangle = 0 \}, \quad T^-_\chi = \{ i \mid \langle \lambda, \beta_i \rangle < 0 \}.
\]

A point \( x \in X \) is stable if it has closed orbit and finite stabilizer. \( X \) has a \( T \)-stable point if and only if for every \( \lambda \in Y(T) \setminus \{0\} \) there exists \( i \) such that \( \langle \lambda, \beta_i \rangle > 0 \) (i.e., not all the weights lie in a half space defined by the hyperplane through the origin).

**In the rest of this section we assume that \( X = W^\vee \) has a \( T \)-stable point.**

### 5.2. Expression of \( \chi \) in terms of faces of \( \Sigma \).

As \( X \) has a \( T \)-stable point, 0 lies in the interior of the positive span of \( (\beta_i)_i \), and in particular \( -\rho + \bigcup_1 r\Sigma = X(T)_0 \), thus every \( \chi \neq -\rho \in X(T) \) lies in the relative interior of a unique proper face of \( -\rho + r\Sigma \) for a unique \( r > 0 \). We will partition the set \( X(T)^+ \) according to the relative interiors of faces of \( -\rho + r\Sigma \) to which its elements belong. However for convenience we will not use the faces directly but rather some equivalent combinatorial data associated to them.

For a set \( S \) let \( \mathcal{P}(S) \) be its power set. We put a partial ordering \( \prec \) on \( \mathbb{R}^+ \times \mathcal{P}(\{1, \ldots, d\})^3 \) by declaring \( (r, S^+, S^-, S^0) \prec (r', S'^+, S'^-, S'^0) \) if either \( r < r' \) or else \( r = r' \), \( S^+ \subset S'^+ \) and \( S^- \subset S'^- \). If \( S = (S^+, S^-, S^0) \) then we write \( |S| = (|S^+|, |S^-|, |S^0|) \).

Let \( \mathbb{R}^+ \times \mathbb{N}^3 \) be equipped with the (total) lexicographic ordering. There is an order preserving map

\[
(\mathbb{R}^+ \times \mathcal{P}(\{1, \ldots, d\})^3, \prec) \to (\mathbb{R}^+ \times \mathbb{N}^3, <) : (r, S) \mapsto (r, |S|)
\]

whose fibers are incomparable among each other.
Lemma-Definition 5.2.1. (1) For \( \chi \neq -\bar{\rho} \in X(T) \) there exists an expression of the form

\[
\chi = -\bar{\rho} - r \sum_{i \in S^+} \beta_i + 0 \sum_{i \in S^-} \beta_i + \sum_{i \in S^0} b_i \beta_i,
\]

where \( S^+ \neq \emptyset, r > 0, \forall i : -r < b_i < 0 \) and \( S^+ \coprod S^- \coprod S^0 = \{1, \ldots, d\} \).

There is a unique tuple \((r_\chi, S_\chi) := (r_\chi, S^+_\chi, S^-_\chi, S^0_\chi)\), for which \((r_\chi, |S_\chi|)\) is minimal among tuples attached to such expression of the form (5.2). If \( \chi = -\bar{\rho} \) then we put by convention \( r_\chi = 0, S^+_\chi = S^-_\chi = 0 \) (although (5.2) is then not true). Below we refer to this situation as the “trivial case”.

(2) If \( \chi \in X(T)^+ \) then there exists \( \lambda \in Y(T)^- \) with the properties: \( S^-_\chi = T^-_\lambda, S^+_\chi = T^+_\lambda, S^0_\chi = T^0_\lambda \).

Remark 5.2.2. If \( \chi \in X(T)^+ \) then the trivial case is equivalent to \( G = T \) and \( \chi = 0 \).

Remark 5.2.3. It will follow from the proof of Lemma 5.2.1 as well as Lemma 5.2.4 below that the data \((r_\chi, S_\chi)\) identifies which proper face \( F \) of \(-\bar{\rho} + r_\chi \Sigma\) contains \( \chi \) in its relative interior. Reformulating Lemma 5.2.4 one has

\[
\text{relint } F = \left\{ -\bar{\rho} - r_\chi \sum_{i \in S^+_\chi} \beta_i + \sum_{i \in S^0_\chi} b_i \beta_i \mid \forall i : -r_\chi < b_i \right\}
\]

Furthermore \( \lambda \) as in Lemma 5.2.1(2) defines an appropriately chosen supporting plane for that face. Finally the \( \prec \)-ordering is opposite to the ordering given by inclusion of faces.

Proof of Lemma 5.2.1. The existence of an expression with minimal \(|S_\chi|\) is obvious. To prove the uniqueness of the associated tuple \((r_\chi, S_\chi)\) assume that there are two minimal expressions with different associated tuples. Taking their average we obtain an expression which is strictly smaller than both the original expressions, contradicting the minimality.

We will now prove (2). If we are in the trivial case then we take \( \lambda = 0 \). So we will now assume we are not in the trivial case. We take \( r \) minimal such that \( \chi \in -\bar{\rho} + r \Sigma \) (and hence \( r_\chi = r \)). By [SvB17a, Lemma C.2] (and as all \( \beta_i \in X(T) \)) there exists \( 0 \neq \lambda \in Y(T) \) such that \( \langle \lambda, \chi \rangle < \langle \lambda, \mu \rangle \) for all \( \mu \in -\bar{\rho} + r \Sigma \) and \( \chi \) can be written as

\[
\chi = -\bar{\rho} - r_\chi \sum_{i \in T^+_\lambda} \beta_i + \sum_{i \in T^0_\lambda} b_i \beta_i,
\]

\(-r_\chi < b_i < 0\). Thus by Lemma 5.2.4 below \( \chi + \bar{\rho} \) is in the relative interior of the face of \( r \Sigma \) defined by the supporting half plane \( \langle \lambda, \chi + \bar{\rho} \rangle \leq \langle \lambda, - \rangle \). Let \( w \in W \) be such that \( w \lambda \in Y(T)^- \). By the discussion preceding the [SvB17a, (11.4)] \( \langle w \lambda, \chi + \bar{\rho} \rangle < \langle w \lambda, - \rangle \) is still a supporting half plane for \( r \Sigma \). It is easy to see that the corresponding face must be equal to \( w F \). Since the face still contains \( \chi + \bar{\rho} \) we must have \( F = w F \). It follows again from Lemma 5.2.4 below that (5.4) remains true with \( \lambda \) replaced by \( w \lambda \). So we now assume \( \lambda \in Y(T)^- \).

By Observation (3) in the proof of [SvB17a, Theorem 1.4.1] (applied to both boundaries of the interval \([-r_\chi, 0]\)) we find that in any expression of the form (5.2) we must have \( T^+_\lambda \subset S^+, T^-_\lambda \subset S^- \). Since \(|S^-_\chi|, |S^+_\chi|\) is minimal this implies \( S^+_\chi = T^+_\lambda, S^-_\chi = T^-_\lambda, S^0_\chi = T^0_\lambda \), establishing (2).
We have used the following result.

**Lemma 5.2.4.** Let \( \chi \in X(T)_R \), \( 0 \neq \lambda \in Y(T)_R \) be such that the equation \( \langle \lambda, \chi \rangle = \langle \lambda, - \rangle \) defines a supporting half-plane of \( \bar{\Sigma} \). Then \( \chi \) is in the relative interior of the corresponding face if and only if \( \chi \) can be written as

\[
\chi = -\sum_{i \in T^+_\lambda} \beta_i + \sum_{i \in T^-_\lambda} b_i \beta_i,
\]

with \(-1 < b_i < 0\).

**Proof.** Let \( H \) be the hyperplane \( \langle \lambda, \chi \rangle = \langle \lambda, - \rangle \). Then \( F = H \cap \bar{\Sigma} \) is given by those \( \mu = \sum_i c_i \beta_i \) such that \( \langle \lambda, \chi \rangle = \langle \lambda, \mu \rangle \) and

\[
\begin{align*}
  i \in T^+_\lambda &\Rightarrow c_i = -1, \\
  i \in T^-_\lambda &\Rightarrow c_i = 0, \\
  i \in T^0_\lambda &\Rightarrow c_i \in [-1, 0].
\end{align*}
\]

This follows in fact from Observation (3) in the proof of [ˇSVdB17a, Theorem 1.4.1] (applied to both boundaries of the interval \([-1, 0]\)). It follows that \( \text{relint } F \) is given by those \( \mu = \sum_i c_i \beta_i \) such that \( \langle \lambda, \chi \rangle = \langle \lambda, \mu \rangle \) and

\[
\begin{align*}
  i \in T^+_\lambda &\Rightarrow c_i = -1, \\
  i \in T^-_\lambda &\Rightarrow c_i = 0, \\
  i \in T^0_\lambda &\Rightarrow c_i \in [-1, 0].
\end{align*}
\]

Applying this with \( \mu = \chi \) yields what we want. \( \Box \)

**Lemma 5.2.5.** Assume that \( \lambda \in Y(T)^- \) corresponds to \( \chi \in X(T)^+ \) as in Lemma 5.2.1(2). Then the following properties hold

1. Let \( \mu \in X(T)^+ \). If \( (r_\chi, S_\chi) \not\leq (r_\mu, S_\mu) \) then \( \langle \lambda, \chi \rangle < \langle \lambda, \mu \rangle \). Similarly if \( (r_\chi, S_\chi) = (r_\mu, S_\mu) \) then \( \langle \lambda, \chi \rangle = \langle \lambda, \mu \rangle \).

2. the sets \( \{ \beta_i | i \in S^+_\lambda \} \), \( \{ \beta_i | i \in S^-_\lambda \} \) are \( W_{G_\lambda} \)-invariant.

**Proof.** (2) is immediate from Lemma 5.2.1(2) since \( \lambda \) is stabilized by \( W_{G_\lambda} \).

Now we verify (1). Again it is sufficient to consider the non-trivial case. The second claim is easy so we discuss the first one. We have

\[
\mu = -\bar{\rho} - r_\mu \sum_{i \in S^+_\mu} \beta_i + \sum_{i \in S^0_\mu} b_i \beta_i,
\]

with \(-r_\mu < b_i < 0\). Write \( \beta_i = \langle \lambda, \beta_i \rangle \). Then using Lemma 5.2.1(2)

\[
\langle \lambda, \chi \rangle = -\langle \lambda, \bar{\rho} \rangle - r_\chi \sum_{i \in T^+_\lambda} \beta_i
\]

(5.5)
If the total inequality will be strict if any of the following conditions hold:

\[(5.8)\]

Then (5.6) holds.

Proof. To prove (1) we have to show

\[(5.7)\]

which is equivalent to any of the following conditions holding

\[S^+ \cap T^-_\lambda \neq \emptyset \quad \text{or} \quad S^0 \cap (T^+_\lambda \cup T^-_\lambda) \neq \emptyset \quad \text{or} \quad (S^+_\mu \cup S^0_\mu) \not\supset T^+_\lambda,\]

which is equivalent to any of the following conditions holding

\[S^+ \not\supset T^+_\lambda \quad \text{or} \quad S^- \not\supset T^-_\lambda \quad \text{or} \quad S^0 \not\supset T^0_\lambda.\]

To prove (1) we have to show

\[(r_\chi, S_\chi) \not\preceq (r_\mu, S_\mu) \Rightarrow \langle \lambda, \chi \rangle < \langle \lambda, \mu \rangle.\]

The condition on the left hand side is equivalent to any of the following conditions holding

\[r_\chi > r_\mu \quad \text{or} \quad r_\chi = r_\mu \text{ and } T^+_\chi \not\subseteq S^+_\mu \quad \text{or} \quad r_\chi = r_\mu \text{ and } T^-_\chi \not\subseteq S^-_\mu.\]

If \(r_\chi > r_\mu\) then \(\langle \lambda, \chi \rangle < \langle \mu, \chi \rangle\) by comparing (5.6) to (5.5) using the fact that

\[S^+_\chi = T^+_\lambda \neq \emptyset.\]

If \(r_\chi = r_\mu\) then (1) follows by comparing (5.7) with (5.8). \(\square\)

Corollary 5.2.6. Let \(\chi \in X(T)^+\) be such that \(r_\chi \geq 1\) and let \(\lambda \in Y(T)^-\) be as in Lemma 5.2.4 [5]. If \(p > 0\) and \(\mu = \chi + \beta_{i_1} + \cdots + \beta_{i_p}\), where \(\{i_1, \ldots, i_p\} \subset\{1, \ldots, d\}\), \(i_j \neq i_j'\) for \(j \neq j'\) and \(\langle \lambda, \beta_{i_j} \rangle > 0\), then \((r_\mu^+, |S_\mu|) < (r_\chi, |S_\chi|)\). Moreover, \(\langle \lambda, \chi \rangle < \langle \lambda, \mu^+ \rangle\).

Proof. By the property (2) in Lemma 5.2.4 every \(k\) for which \(\langle \lambda, \beta_k \rangle > 0\) belongs to \(S^+\) and thus \(r_\mu < r_\chi\) or \(r_\mu = r_\chi\) and \(|S_\mu| < |S_\chi|\). In other words \((r_\mu, |S_\mu|) < (r_\chi, |S_\chi|)\).

As \((r_\mu, |S_\mu|)\) depends only on the \(W\)-orbit of \(\mu\) for the \(*\)-action, we also have \((r_\mu^+, |S_\mu|) < (r_\chi, |S_\chi|)\) and hence \((r_\mu^+, |S_\mu|) \not\preceq (r_\chi, |S_\chi|)\). Property (1) in Lemma 5.2.5 implies \(\langle \lambda, \mu^+ \rangle > \langle \lambda, \chi \rangle\). \(\square\)
Lemma 5.2.7. Let \( \chi \in X(T)^+ \) and let \( \lambda \) be as in Lemma 5.2.1(2). Then the set
\[
\{ \chi' \in X(T)^+ \mid (r_{\chi'}, S_{\chi'}) = (r_{\chi}, S_{\chi}) \}
\]
is equal to
\[
(\nu - \bar{\rho}_\lambda + r_{\chi} \Sigma^0_{\lambda}) \cap X(T)^+
\]
where
\[
\nu = -\bar{\rho} + \bar{\rho}_\lambda + \chi_p.
\]
Moreover \( \nu \) is \( W_{G^\lambda} \)-invariant.

Proof. The fact that \( \nu \) is \( W_{G^\lambda} \)-invariant is a direct consequence of Lemma 5.2.5(2) and the standard fact that \(-\bar{\rho} + \bar{\rho}_\lambda \) is \( W_{G^\lambda} \)-invariant.

By Lemma 5.2.1 and (5.3) we have
\[
\{ \chi' \in X(T)^+ \mid (r_{\chi'}, S_{\chi'}) = (r_{\chi}, S_{\chi}) \} = (-\bar{\rho} + \chi_p + r_{\chi} \Sigma^0_{\lambda}) \cap X(T)^+.
\]

By Lemma 5.2.8 below we may rewrite this as
\[
\{ \chi' \in X(T)^+ \mid (r_{\chi'}, S_{\chi'}) = (r_{\chi}, S_{\chi}) \} = (-\bar{\rho} + \chi_p + r_{\chi} \Sigma^0_{\lambda}) \cap X(T)^\lambda
\]
which is the same as
\[
(\nu - \bar{\rho}_\lambda + r_{\chi} \Sigma^0_{\lambda}) \cap X(T)^\lambda.
\]

We have used the following result.

Lemma 5.2.8. Let \( \chi \in X(T)^+ \) and let \( \lambda \) be as in Lemma 5.2.1(2). If \( \chi \in X(T)^+ \) and \( \chi' \in X(T)^\lambda \) are such that \( (r_{\chi'}, S_{\chi'}) = (r_{\chi}, S_{\chi}) \) then \( \chi' \in X(T)^+ \).

Proof. We assume that we are not in the trivial case otherwise there is nothing to do. We first verify \( s_{\alpha} \cdot \chi' \neq \chi' \) for all \( \alpha \in W \). This implies that \( \chi' \) exists. Assume on the contrary that \( s_{\alpha} \cdot \chi' = \chi' \) for some \( \alpha \). By the uniqueness of the minimal expression in Lemma 5.2.1 we obtain that \( S^+_{\chi'} = S^+_{\chi} = T^+_{\lambda} \) is \( s_{\alpha} \)-invariant. Using the formula (5.3) we find \( \langle \lambda, \chi' \rangle = \langle \lambda, s_{\alpha} \cdot \chi \rangle \). Then Lemma 5.1.1 implies \( s_{\alpha} \in W_{G^\lambda} \).

However this is excluded by the fact that \( s_{\alpha} \cdot \chi' = \chi' \) and \( \chi' \in X(T)^\lambda \).

Assume \( \chi' \notin X(T)^+ \). By the above discussion there exists \( 1 \neq w \in W \) such that \( w \cdot \chi' \) is dominant. Furthermore \( w \notin W_{G^\lambda} \) as \( \chi' \in X(T)^\lambda \). Then Lemma 5.1.1 implies \( \langle \lambda, w \cdot \chi' \rangle < \langle \lambda, \chi' \rangle = \langle \lambda, \chi \rangle \).

As \( (r_{w \cdot \chi'}. S_{w \cdot \chi'}) = (r_{\chi'}, S_{\chi'}) \) we deduce \( (r_{\chi}, S_{\chi}) \neq (r_{w \cdot \chi'}, S_{w \cdot \chi'}) \).

Then property (11) in Lemma 5.2.8 implies \( \langle \lambda, \chi \rangle \leq \langle \lambda, w \cdot \chi' \rangle \). This is a contradiction.

5.3. \( G/G_e \)-action on \( X(T)^+ \). Here we allow \( G \) to be non-connected. \( W \) is still a \( G \)-representation. We apply the previous results with \( G \) replaced by \( G_e \). In particular \( T \subset B \subset G_e \). As we have seen in (3.7) the group \( G/G_e \) acts on \( X(T)^+ \) via \( g(\chi) = \chi \circ \sigma_g^{-1} \).

Since \( G/G_e \) also acts on the weights on \( W \), it may be made to act on \( \{1, \ldots, d\} \) via \( g(i) = j \) if \( \beta_j = \beta_i \circ \sigma_g^{-1} \). This action extends to an action of \( G/G_e \) on the partially ordered set \( (\mathbb{R}^+ \times \mathcal{P}(\{1, \ldots, d\}))^3, \prec) \) introduced above.
Lemma 5.3.1. The map
\[
(X(T)^+) \to \mathbb{R}^+ \times \mathcal{P}(\{1, \ldots, d\})^3 : \chi \mapsto (r_\chi, S_\chi)
\]
is $G/G_e$-equivariant. Moreover if $\chi \in X(T)^+$, $\bar{g} \in G/G_e$ and $\lambda \in Y(T)^-$ is as in Lemma 5.2.1(2), then $\sigma_{\bar{g}} \circ \lambda \in Y(T)^-$ satisfies property (2) in Lemma 5.2.1 for $\chi \circ \sigma_{\bar{g}}$. Consequently, $(T_\sigma^\pm, T^0_\sigma)$ for $\chi \circ \sigma_{\bar{g}}$.

Proof. Let $\chi \in X(T)^+$. As usual we may assume we are in the non-trivial case. We obtain an expression of $\chi \circ \sigma_{\bar{g}}$ of the form (5.2) with $\beta_i$ replaced by $\beta_i \circ \sigma_{\bar{g}}$. Since this expression in minimal for $\chi \circ \sigma_{\bar{g}}$ (as otherwise applying $- \circ \sigma_{\bar{g}}^{-1}$ would give a smaller expression for $\chi$), $(r_{\chi \circ \sigma_{\bar{g}}}, S_{\chi \circ \sigma_{\bar{g}}}) = \tilde{g}^{-1}(r_\chi, S_\chi)$.

As $\langle \lambda, \beta \circ \sigma_{\bar{g}} \rangle = \langle \sigma_{\bar{g}} \circ \lambda, \beta \rangle$ for all $\beta \in X(T)$, it easy to verify $\sigma_{\bar{g}} \circ \lambda \in Y(T)^-\bar{g}$ satisfies property (2) in Lemma 5.2.1 for $\chi \circ \sigma_{\bar{g}}$. This implies in particular the last assertion of the lemma. \hfill \Box

5.4. Reduction settings. Here we allow $G$ to be again non-connected.

Lemma 5.4.1. There exists a total ordering $< \in \mathbb{R}^+ \times \mathcal{P}(\{1, \ldots, d\})^3$ such that the following conditions hold.

1. If $(r, [S]) < (r', [S'])$ then $(r, S) < (r', S')$.
2. If $(r, S) < (r', S')$ and $(r, S)$ and $(r', S')$ are in different $G/G_e$-orbits then $\bar{g}(r, S) < \bar{h}(r', S')$ for all $\bar{g}, \bar{h}$ in $G/G_e$.

Proof. The map (5.1) is $G/G_e$-equivariant. We choose an arbitrary totally ordering on the fibers of (5.1) compatible with condition (2). Combining this with (1) completely fixes $<$. \hfill \Box

Remark 5.4.2. It is clear that any total ordering $<$ as in Lemma 5.4.1 refines the partial ordering $\prec$.

Lemma-Definition 5.4.3. It is possible to choose for any $\chi \in X(T)^+$ a $\lambda_\chi \in Y(T)^-$ such that the following conditions are satisfied

1. $\lambda = \lambda_\chi$ satisfies the property (2) in Lemma 5.2.1
2. If $(r_\chi, S_\chi) = (r_\chi, S_\chi)$ then $\lambda = \lambda_\chi$.
3. We have $\lambda_{\chi \circ \sigma_{\bar{g}}} = \sigma_{\bar{g}} \circ \lambda_\chi$ for all $\bar{g} \in G/G_e$.
4. If $\bar{g}(T^\pm_{\lambda_\chi}, T^0_{\lambda_\chi}) = (T^\pm_{\lambda_\chi}, T^0_{\lambda_\chi})$ then $\sigma_{\bar{g}} \circ \lambda_\chi = \lambda_\chi$.

Proof. Choose representatives $(r_\chi, S_\chi)$ for the orbits of the $G/G_e$-action on the image of (5.10). For each $i$ choose $\lambda'_i \in Y(T)^-$ such that $S^-_{\chi_i} = T^0_{\lambda'_i}$, $S^+_{\chi_i} = T^0_{\lambda'_i}$, $S^0_{\chi_i} = T^0_{\lambda'_i}$ as in Lemma 5.2.1(2). Let $G_i \subset G/G_e$ be the stabilizer of $(r_{\chi_i}, S_{\chi_i})$ and put $\lambda_i = \sum_{\bar{g} \in G_i} \sigma_{\bar{g}} \circ \lambda'_i$. Then it is easy to see that we still have $S^-_{\chi_i} = T^0_{\lambda_i}$, $S^0_{\chi_i} = T^0_{\lambda'_i}$, and moreover $\sigma_{\bar{g}} \circ \lambda_i = \lambda_i$ if $\bar{g} \in G_i$.

Now for $\chi \in X(T)^+$ write $(r_\chi, S_\chi) = \bar{h}(r_{\chi_i}, S_{\chi_i})$ for suitable $i$ and $\bar{h} \in G/G_e$. Then we put $\lambda_\chi = \sigma_{\bar{h}} \circ \lambda_i$. It is clear that this is well defined and has the requested properties. \hfill \Box

Lemma 5.4.4. Let $(\lambda_\chi)_{\chi}$ be as in Lemma 5.4.3. We have for $\bar{g} \in G/G_e$:

$$(\lambda_\chi, \bar{g}(\chi)) \geq (\lambda_\chi, \chi)$$

with equality if and only if $\bar{g} \in (G/G_e)^{\lambda_\chi}$. 

Proof. By (5.10) we have
\[(r_{\tilde{g}(\chi)}, S_{\tilde{g}(\chi)}) = \tilde{g}(r_{\chi}, S_{\chi}).\]
Hence in particular
\[(r_{\tilde{g}(\chi)}, |S_{\tilde{g}(\chi)}|) = (r_{\chi}, |S_{\chi}|)\]
and so \((r_{\chi}, S_{\chi}) \neq (r_{\tilde{g}(\chi)}, S_{\tilde{g}(\chi)})\). It follows from Lemma 5.2.6 that
\[(\lambda_{\chi}, \chi) \leq (\lambda_{\chi}, \tilde{g}(\chi)).\]
Also by Lemma 5.2.5 equality will happen precisely when \((r_{\tilde{g}(\chi)}, S_{\tilde{g}(\chi)}) = (r_{\chi}, S_{\chi})\)
which by (5.11) implies that \(\tilde{g}\) stabilizes \(S_{\chi} = (T_{\chi}^{+}, T_{\chi}^{-}, T_{\chi}^{0})\). By Lemma 5.4.4 this implies \(\tilde{g} \in (G/G_{e})^{\chi}\).

Below we fix \((\lambda_{\chi})_{\chi}\) as in Lemma 5.4.3 and we choose a total ordering on \(\mathbb{R}^{+} \times \mathcal{P}(\{1, \ldots, d\})^{3}\) as in Lemma 5.4.1. We put the induced ordering on \(I := \{(r_{\chi}, S_{\chi}) \mid \chi \in X(T)^{+}\} \subset \mathbb{R}^{+} \times \mathcal{P}(\{1, \ldots, d\})^{3}\). As a totally ordered set we have \(I \cong \mathbb{N}\). For \(i \in I\) we put \(F_{i} = \{\chi \in X(T)^{+} \mid (r_{\chi}, S_{\chi}) = i\}\). This gives a \(G/G_{e}\)-equivariant partition
\[(5.12) \quad X(T)^{+} = \bigsqcup_{i \in I} F_{i}.
\]
In each \(F_{i}\) we choose one representative which we denote by \(\chi_{i}\). We write \(\lambda_{i} = \lambda_{\chi_{i}}, r_{i} = r_{\chi_{i}}, S_{i} = S_{\chi_{i}}\). By our choice of \(\lambda_{\chi}\) and the definition of \(F_{i}\), \((r_{i}, \lambda_{i}, S_{i})\) depends only on \(i \in I\) and not on the choice of \(\chi_{i} \in F_{i}\).

For \(j \in I\) we write
\[
L_{<j} = \bigcup_{i \in I, i < j} F_{i} \subset X(T)^{+},
\]
\[
L_{\leq j} = \bigcup_{i \in I, i \leq j} F_{i} \subset X(T)^{+}.
\]
Let \(J \subset I\) be the minimal representatives for the orbits of the action of \(G/G_{e}\) on \(I\).

By the choice of \(J\) and property (2) in Lemma 5.4.1 the set \(\{i \in I \mid i < j\}\) is \(G/G_{e}\)-invariant if \(j \in J\) and hence the same is true for \(L_{<j}\).

**Corollary 5.4.5.** Let \(j \in J\) with \(r_{j} \geq 1\) and \(\chi \in F_{j}\). Then \((G, B, T, X, L_{<j}, \chi, \lambda_{j})\) is a reduction setting.

**Proof.** We may reduce to the case that \(X\) is affine. Then by Theorem 4.4.1 and Proposition 4.3.1 we may assume \(G = G_{e}\) and \(X = W^{\vee}\). Thus we need to verify the assumptions of Proposition 4.5.1. They are satisfied by Corollary 5.2.6 due to the choice of \(\lambda_{j} = \lambda_{\chi}\) for every \(\chi \in F_{j}\). \(\square\)

6. Proofs of the semi-orthogonal decompositions

In this section we will prove Theorem 1.1.2 and along the way we will also prove Proposition 1.2.2 and Corollary 7.2. We continue to use the notations introduced in the previous section.

For the proof of Theorem 1.1.2 we select a finite open affine covering \(X/G = \bigsqcup_{i} U_{i}\) and put \(X_{i} = \pi^{-1}(U_{i})\). Thus \(X = \bigsqcup_{i} X_{i}\) for \(G\)-equivariant affine \(G\)-varieties \(X_{i}\). We choose a \(G\)-representation \(W\) such that \(W^{\vee}\) has a \(T\)-stable point together with a closed \(G\)-equivariant embedding \(\bigsqcup_{i} X_{i} \hookrightarrow W^{\vee}\). We use \(W\) to construct
Proof. (1) We claim that Proposition 6.1. The arguments below will be based on “reduction to the affine case”, i.e. to one of the $X_i$.

For $j \in I$ let $\mathcal{D}_{<j}$ be the triangulated subcategories of $\mathcal{D}(X/G)$ locally classically generated by $P_{\mathcal{L}_{<j}}$, $P_{\mathcal{L}_{<j}}$ as in (5.5) and put $\Lambda_{<j} = \pi_* \mathcal{E}nd_{X/G}(P_{\mathcal{L}_{<j}})$.

For $j \in J$ let $\mathcal{D}_j$ be the triangulated subcategory of $\mathcal{D}(X/G)$ locally classically generated by $(\mathcal{R}\text{Ind}_{\mathcal{L}_{<j},\chi}^\circlearrowleft (V_{\mathcal{L}_{<j}}(\chi) \otimes \mathcal{O}_{\mathcal{L}_{<j},+}) \mid \chi \in F_j)$.

For a $\mathcal{W}_{\mathcal{G}_x}$-invariant $\nu \in X(T)_R$ we put

$$L_{r,\lambda,\nu} = X(T)^\lambda \cap (\nu - \bar{\rho}_\lambda + r\Sigma^0),$$

$$U_{r,\lambda,\nu} = \bigoplus_{\mu \in \mathcal{L}_{r,\lambda,\nu}} \text{Ind} H^\lambda_{\mathcal{G}_x} \mathcal{V}_{\mathcal{G}_x}(\mu),$$

$$\Lambda_{r,\lambda,\nu} = (\text{End}(U_{r,\lambda,\nu}) \otimes_k \mathcal{O}_{X^\lambda})^H.$$

Proposition 12.2 and Theorem 12.2 will be consequences of the following proposition.

Proposition 6.1. (1) If $j \notin J$ then $\mathcal{D}_{<j} = \mathcal{D}_{\leq j}$.

Assume that $j \in J$ is such that $r_j \geq 1$. Then

(2) $\mathcal{D}_{<j} \cong D(\Lambda_{<j})$ and $\Lambda_{<j}$ has finite global dimension when restricted to affine opens in $X/G$.

(3) $\mathcal{D}_j \cong D(\Lambda_{r_j,\lambda_j,\nu_j})$ for $\nu_j = -\bar{\rho} + \bar{\rho}_{\lambda_j} + (\chi_j)_p$ (where $(\chi_j)_p$ was introduced in (5.2) and $\Lambda_{r_j,\lambda_j,\nu_j}$ has finite global dimension when restricted to affine opens in $X/G$.

(4) $\mathcal{D}_{\leq j} = \langle \mathcal{D}_j, \mathcal{D}_{<j} \rangle$ is a semi-orthogonal decomposition of $\mathcal{D}_{\leq j}$.

(5) One has $\mathcal{D}(X/G) = \bigcup_{j \in J} \mathcal{D}_j$.

Proof. (1) We claim that $\bigoplus_{\chi \in \mathcal{L}_{<j}} V(\chi) = \bigoplus_{\chi \in \mathcal{L}_{<j}} V(\chi)$. We only have to prove that if $\chi \in F_j$ then $V(\chi)$ is a summand of $\bigoplus_{\chi \in \mathcal{L}_{<j}} V(\chi)$. Since $j \notin J$ there is $\bar{g} \in G/G_x$ such that $\bar{g}(j) \not\in j$. Put $\chi' = \bar{g}(\chi) \in F_{\bar{g}(j)} \subset \mathcal{L}_{<j}$. Using (5.2), (4.10) we obtain

$$V(\chi') = \text{Ind}_{\mathcal{G}_x}^{\mathcal{G}_x} V_{\mathcal{G}_x}(\chi')$$

$$= \text{Ind}_{\mathcal{G}_x}^{\mathcal{G}_x} V_{\mathcal{G}_x}(\chi)$$

$$\cong \text{Ind}_{\mathcal{G}_x}^{\mathcal{G}_x} V_{\mathcal{G}_x}(\chi)$$

$$= V(\chi).$$

(2) The fact that $\mathcal{D}_{<j} = D(\Lambda_{<j})$ follows from Lemma 5.5.6. To prove that $\Lambda_{<j}$ is locally of finite global dimension we may restrict to the case that $X$ is affine. To prove that $\text{gldim} \Lambda_{<j} < \infty$, by [SVdB17a] Thm. 4.3.1, Lem. 4.5.1 it suffices to consider the case $X = W^v$ and $G = G_x$. We denote $\mathcal{P}_{\mathcal{L}_{<j},\chi} = \text{Hom}_{X/G}(P_{\mathcal{L}_{<j}}, P_{\chi})$. By [SVdB17a] Lem. 11.1.1 it is enough to show that $\text{pd} \mathcal{P}_{\mathcal{L}_{<j},\chi} < \infty$ for every $\chi \in X(T)^+$. Assume that there exists $\chi$ such that $\text{pd} \mathcal{P}_{\mathcal{L}_{<j},\chi} = \infty$ and take $\chi \in X(T)^+$ with minimal $(r_{\chi},|S_\chi|)$. Then $(r_{\chi},|S_\chi|) \nleq (r_{\mu},|S_\mu|)$ for all $\mu \in \mathcal{L}_{<j}$ (for otherwise $\chi \in \mathcal{L}_{<j}$ and hence $\text{pd} \mathcal{P}_{\mathcal{L}_{<j},\chi} = 0$). Let $\lambda = \lambda_{\chi}$. It follows from Lemma 5.2.3 (1) that $\langle \lambda, \chi \rangle < (\lambda, \mu)$ for all $\mu \in \mathcal{L}_{<j}$. Thus, $C_{\mathcal{L}_{<j},\lambda,\chi} := \text{Hom}_{X/G}(P_{\mathcal{L}_{<j}}, C_{\lambda,\chi})$ is acyclic by (4.13) and the fact that the $\lambda$-weights of $k[X^{\lambda,+}]$ are $0$ (see 3.2). We have $(r_{\chi'},|S_{\chi'}|) < (r_{\lambda},|S_{\lambda}|)$.
for all $\tilde{P}_{L_{<j},\chi} \neq \tilde{P}_{L_{<j},\chi}'$ that appear in $C_{L_{<j},\chi}$ by (4.15) and Corollary 5.2.6. Hence $\text{pdim } \tilde{P}_{L_{<j},\chi} < \infty$ by the minimality assumption, and therefore $\text{pdim } \tilde{P}_{L_{<j},\chi}' < \infty$, a contradiction.

Now we use the fact that $(G, B, T, X, L_j, \chi)$ is a reduction setting for $\chi \in F_j$ by Corollary 5.4.5. Let us abbreviate $D_{j,\chi} = R\text{Ind}_{G_{\lambda_j}}^{G_{\lambda_j}+}(V_{G_{\lambda_j}+}(\chi) \otimes_k \mathcal{O}_{X_{\lambda_j}+})$. By Proposition 4.2.1 we have

$$\pi_* \mathcal{E}nd_{X/G}(\bigoplus_{\chi \in F_j} D_{j,\chi}) = \pi_* \mathcal{E}nd_{X/H^\lambda}(\bigoplus_{\chi \in F_j} P_{H^\lambda,\chi})$$

and the latter is equal to $\Lambda_{r_j, \lambda_j, \nu_j}$ by Lemma 5.2.7.

To prove that $\Lambda_{r_j, \lambda_j, \nu_j}$ locally has finite global dimension we may reduce to the affine case. Then by [ˇSVdB17a, Thm. 4.3.1, Lem. 4.5.1] we may reduce to the case $G = G_e$ and $X = W^\vee$. Finally we invoke Proposition 1.2.1.

(5) This follows from Lemma 3.5.4.

Proof of Theorem 1.1.2. Put

$$j_0 = \min\{j \in J \mid r_j \geq 1\}.$$ 

Then we have by Lemma 3.5.6 $D_{\leq j_0} = D(\Lambda_{1,0,0})$. Now write

$$\{j \in J \mid r_j \geq 1\} = \{j_0, j_1, j_2, \ldots\}.$$ 

Put $D_0 = D_{\leq j_0}$. And for $i > 0$ let $D_{-i}$ be the right orthogonal of $D_{\leq j_{i-1}} = D_{<j_i}$ in $D_{\leq j_i}$. By Proposition 6.1 (1), (4), (5) we have a semi-orthogonal decomposition

$$D(X/G) = \langle \ldots, D_{-2}, D_{-1}, D_0 \rangle$$

and by Proposition 6.1 (3) each of the $D_{-1}, D_{-2}, \ldots$ has the required form. The corresponding statement for $\tilde{D}_{X/G}$ follows by replacing $X/G$ by open subschemes. \qed

Remark 6.2. If follows from Lemma 3.5.7 that $D_{-j} \subset D(X/G)$ and $D_{\leq j}$ for $j \in J$ are admissible.

Proof of Proposition 1.2.2. This corresponds to the special case $X = W^\vee$ in the proof of Theorem 1.1.2. \qed

7. The case that $X$ does not have a $T$-stable point.

In this section we will assume throughout that $G$ is connected and that $X$ is a connected smooth $G$-variety such that a good quotient $X/G$ exists. We will give an alternative semi-orthogonal decomposition of $D(X/G)$ in case $X$ does not have a $T$-stable point.

Lemma 7.1. Assume that $X$ does not have a $T$-stable point. Then at least one of the following settings holds:

(1) There is a non-trivial normal connected subgroup $K$ of $G$ acting trivially on $X$.

(2) There is a non-trivial central one parameter group $\nu : G_m \to Z(G)$ such that $X = X^{\nu,+}$.
Proof. Since $X$ does not have a $T$-stable point we have

$$X = \bigcup_{\sigma \in X(T) - \{0\}} X^{\sigma, +}. \tag{7.1}$$

It is well-known and easy to see that there are only a finite number of distinct $X^{\sigma, +}$. Indeed: by covering $X/G$ by a finite number of affines, it suffices to verify this in the affine case and then it follows by embedding $X$ into a representation. Hence since the union in (7.1) is finite and $X$ is irreducible we find that there is some $\sigma \in X(T) - \{0\}$ such that $X = X^{\sigma, +}$.

It follows that $X = X^{w\sigma, +}$ for every $w \in \mathcal{W}$. Put $\nu = \sum_{w \in \mathcal{W}} w\sigma$. Then $\nu$ is a $\mathcal{W}$-invariant 1-parameter subgroup of $T$ and in particular its image is contained in the center of $G$.

We claim $X^{\nu, +} = X$, $X^{\nu} \subset X^\sigma$. We may check this in the case that $X$ is affine. Let $C \subset X(T)_R$ be the cone spanned by the weights of $k[X]$. Since $X^{\nu, +} = X$ we have $\langle \sigma, C \rangle \leq 0$. Since $C$ is $\mathcal{W}$-invariant we immediately deduce $\langle \nu, C \rangle \leq 0$ and hence $X^{\nu, +} = X$.

To prove $X^{\nu} \subset X^\sigma$ we have to verify that if $\chi \in C$ and $\langle \nu, \chi \rangle = 0$ then $\langle \sigma, \chi \rangle = 0$. To prove this it suffices to observe that $\langle \nu, \chi \rangle = \sum_{w \in \mathcal{W}} \langle \sigma, w^{-1} \chi \rangle$ and this can only be zero if $\langle \sigma, w^{-1} \chi \rangle = 0$ for all $w \in \mathcal{W}$.

If $\nu \neq 0$ then we are in situation (2). If $\nu = 0$ then $X^{\nu} = X$. Hence also $X^{\nu} = X$ by the above discussion. Therefore (1) holds with $K$ being the identity component of ker($G \to Aut(X)$). The group $K$ is not trivial as it contains $im \sigma$. \hfill $\square$

To continue it will be convenient to slightly generalize our setting in a similar way as [SVdB17a Thm 1.6.3]. We will however use different notations which are more adapted to the current setting. We will assume that $G$ contains a finite central subgroup $A$ acting trivially on $X$ with $\tilde{G} := G/A$. Let $X(A) := \text{Hom}(A, G_m)$ be the character group of $A$. For $\tau \in X(A)$ let $\mathcal{D}(X/G)_\tau$ be the triangulated subcategory of $\mathcal{D}(X/G)$ consisting of complexes on which $A$ acts as $\tau$. We have an orthogonal decomposition

$$\mathcal{D}(X/G) = \bigoplus_{\tau \in X(A)} \mathcal{D}(X/G)_\tau \tag{7.2}$$

and moreover $\mathcal{D}(X/G)_0 = \mathcal{D}(X/\tilde{G})$. In general we should think of $\mathcal{D}(X/G)_\tau$ as a twisted version of $\mathcal{D}(X/\tilde{G})$.

**Proposition 7.2.** Let $\tau \in X(A)$. Then there exists a semi-orthogonal decomposition of $\mathcal{D}(X/G)_\tau$ of the form described in Theorem 1.1.3.

**Proof.** Let the notation be as in [6]. We have $A \subset T$. Let $\bar{T} = T/A$. Then there is an exact sequence

$$0 \to X(\bar{T}) \to X(T) \to X(A) \to 0. \tag{7.3}$$

Let $X(\bar{T})_\tau \subset X(T)$ be the inverse image of $\tau \in X(A)$. Let $\chi \in F_j \cap X(\bar{T})_{\tau}$. Since $A$ acts trivially on $X$, it acts with the character $\tau$ on the right-hand side of (1.3) with $\mathcal{L} = \mathcal{L}_{<j}$. Since $\pi_{\ast \ast} \mathcal{H}om_{X/G}(P_{G, \chi'}, P_{G, \chi}) = 0$ if $\chi' \notin X(T)_{\tau}$, (1.3) is thus still an
isomorphism if we replace \( \mathcal{L}_{<j} \) by \( \mathcal{L}_{<j,\tau} = \mathcal{L}_{<j} \cap X(\bar{T})_{\tau} \). Put
\[
\Lambda_{<j,\tau} = \pi_{ss} \text{End}_{X/G}(P_{\mathcal{L}_{<j,\tau}}),
\]
\[
\Lambda_{j,\tau} = X(\bar{T})^{\lambda_j} \cap (\nu - \bar{p}_{\lambda_j} + r_j \Sigma_j^0),
\]
\[
U_{j,\tau} = \bigoplus_{\mu \in \mathcal{L}_{j,\tau}} \text{Ind}_{G_{\lambda_j}}^{U_{\lambda_j}} V_{\lambda_j}^\mu(\mu),
\]
\[
\Lambda_{j,\tau} = (\text{End}(U_{j,\tau}) \otimes_k \mathcal{O}_{X^{\lambda_j}})^{H_{\lambda_j}}.
\]
We have \( \Lambda_{<j} = \bigoplus_{\tau \in X(A)} \Lambda_{<j,\tau}, \Lambda_j = \bigoplus_{\tau \in X(A)} \Lambda_{j,\tau}. \) As \( \Lambda_{<j} \) and \( \Lambda_j \) have finite global dimension when restricted to affine opens in \( X/G \), the same holds for \( \Lambda_{<j,\tau}, \Lambda_{j,\tau}. \) Arguing as above we thus obtain a semi-orthogonal decomposition \( \mathcal{D}_{<j,\tau} = \langle \mathcal{D}_{j,\tau}, \mathcal{D}_{<j,\tau} \rangle \) (with the obvious definitions for \( \mathcal{D}_{j,\tau}, \mathcal{D}_{<j,\tau} \), \( \mathcal{D}_{<j,\tau} \cong \mathcal{D}(\Lambda_{<j,\tau}), \mathcal{D}_{j,\tau} \cong \mathcal{D}(\Lambda_{j,\tau}) \)). Then the proof continues as before. \( \square \)

If \( K \) is a connected normal subgroup of \( G \) then we will define a pseudo-complement of \( K \) as a connected normal subgroup \( Q \) of \( G \) such that \( K \) and \( Q \) commute, \( G = KQ \) and \( K \cap Q \) is finite. It follows easily from [Spr98, Theorem 8.1.5, Corollary 8.1.6] that such a pseudo-complement always exists.

**Proposition 7.3.** Assume \( X \) does not have a \( T \)-stable point and that we are in the situation of Lemma [7.4]. Let \( Q \) be a pseudo-complement of \( K \) in \( G \). Then there is a finite central subgroup \( A_Q \) of \( Q \) acting trivially on \( X \) such that there is an orthogonal decomposition
\[
\mathcal{D}(X/G)_{\tau} \cong \bigoplus_{\mu \in \mathcal{L}_{\tau}} \mathcal{D}(X/Q)_{\mu},
\]
for a suitable collection of \( (\mu_i)_{i \in I} \in X(A_Q) \).

**Proof.** Let \( \tilde{G} := K \times Q \to G \) be the multiplication map and let \( \tilde{A} \subset K \times Q \) be the inverse image of \( A \). Let \( A_K \subset K, A_Q \subset Q \) be the images of \( \tilde{A} \) under the projections \( K \times Q \to K, Q \). It is easy to see that \( A_Q \) acts trivially on \( X \). Let \( \tilde{\tau} \) be the composition \( \tilde{A} \to A \xrightarrow{\tau} G_m. \) In a similar way, if \( \mu \in X(A_K) \) or \( \mu \in X(A_Q) \) then we denote by \( \tilde{\mu} \) the element of \( X(\tilde{A}) \), obtained by composing \( \mu \) with the appropriate projections \( \tilde{A} \to A_K, A_Q. \)

We have
\[
\mathcal{D}(X/G)_{\tau} = \mathcal{D}(X/\tilde{G})_{\tilde{\tau}}.
\]
Let \( \text{Irr}(K) \) be the set of isomorphism classes of irreducible representations of \( K \). We have an orthogonal decomposition
\[
\bigoplus_{V \in \text{Irr}(K)} \mathcal{D}(X/Q) \to \mathcal{D}(X/\tilde{G}) : (\mathcal{F}_V)_{\tau} \mapsto \bigoplus_{V \in \text{Irr}(K)} V \otimes_k \mathcal{F}_V.
\]
If \( V \in \text{Irr}(K) \) then \( A_K \) acts on \( V \) via a character which we denote by \( \chi_V \in X(A_K). \) Combining (7.5) and (7.6) yields
\[
\mathcal{D}(X/G)_{\tau} \cong \bigoplus_{(\mu, \nu) \in X(A_Q) \times \text{Irr}(K), \tilde{\mu} + \tilde{\chi}_V = \tilde{\tau}} \mathcal{D}(X/Q)_{\mu}
\]
which implies (7.4). \( \square \)
Proposition 7.4. Assume $X$ does not have a $T$-stable point and that we are in the situation of Lemma 7.2. Let $Q$ be a pseudo-complement of $\text{im} \nu$ in $G$. Then there is a finite central subgroup $A_Q$ of $Q$ acting trivially on $X^\nu$ such that there is a semi-orthogonal decomposition
\[(7.7) \quad \mathcal{D}(X/G)_\nu = \langle \mathcal{D}(X^\nu/Q)_{\mu_i} \mid i \in I \rangle \]
for a suitable totally ordered set $I$ and a collection of $(\mu_i)_{i \in I} \in X(A_Q)$.

Proof. Without loss of generality we may, and we will, assume that $\nu$ is injective. We put $K = \text{im} \nu \cong G_m$ and we borrow the associated notation from the proof of Proposition 7.3. One checks that in this case $A_Q$ acts indeed trivially on $X^\nu$. The set $\text{Irr}(K)$ is equal to $\{ (\chi_n)_n \}$ where $\chi_n \in X(K)$ is such that $\chi_n(z) = z^n$.

We know by Lemma 3.5.4 that $\mathcal{D}(X/\hat{G})$ is locally classically generated by $P_{n,V} := (\chi_n \otimes_k V \otimes_k \mathcal{O}_X)_{n,V}$, with $n \in \mathbb{Z}$, $V \in \text{Irr}(Q)$. We also put $P^\nu_V := V \otimes_k \mathcal{O}_{X^\nu} \in \mathcal{D}(X^\nu/Q)$. We claim that if $n \leq m$ one has
\[(7.8) \quad \pi_{s,*} R\text{Hom}_{X/\hat{G}}(P_{n,V}, P_{m,V'}) = \begin{cases} 0 & \text{if } n < m \\ \pi_{s,*} j_{s,*} R\text{Hom}_{X^\nu/Q}(P^\nu_V, P^\nu_{V'}) & \text{if } n = m \end{cases} \]
where $j : X^\nu \to X$ is the embedding and $j_s : X^\nu/Q \to X/\hat{G}$ is the corresponding map of quotient stacks.

To prove this may reduce to the case that $X/\hat{G}$ is affine. Then as usual $\nu$ induces a grading on $k[X]$ which, as $\nu$ is central, is compatible with the $G$-action.

In the affine case $\pi_{s,*} R\text{Hom}_{X/\hat{G}}(P_{n,V}, P_{m,V'})$ is the quasi-coherent sheaf on $X/\hat{G}$ associated to the $k[X^\nu]^G$-module given by $(\text{Hom}(V,V') \otimes_k k[X]_{m-n})^\hat{G}$ which is zero if $n < m$ since the hypothesis $X = X^{\nu,+}$ implies that the grading on $k[X]$ is concentrated in negative degree. Similarly if $n = m$ then we have $(\text{Hom}(V,V') \otimes_k k[X]_{m-n})^\hat{G} = (\text{Hom}(V,V') \otimes_k k[X^\nu])^Q$ finishing the proof of (7.8).

Let $\mathcal{D}_n \subset \mathcal{D}(X/\hat{G})$ be locally classically generated by $(P_{-n,V})_{V \in \text{Irr}(Q)}$. Then using Proposition 3.5.8 and (7.8) we see that we have a semi-orthogonal decomposition
\[(7.9) \quad \mathcal{D}(X/\hat{G}) = \langle \mathcal{D}_n \mid n \in \mathbb{Z} \rangle.\]
The next step is to describe the $\mathcal{D}_n$. We claim that there is an equivalence of categories
\[(7.10) \quad \mathcal{D}_n \to \mathcal{D}(X^{\nu}/Q) : F \mapsto \chi_n \otimes_k Lj^*_n(F).\]
Let $F, F' \in \mathcal{D}_n$. We have to prove that the natural map
\[
\pi_{s,*} R\text{Hom}_{X/\hat{G}}(F, F') \to \pi_{s,*} R\text{Hom}_{X^\nu/Q}(\chi_n \otimes_k Lj^*_n(F), \chi_n \otimes_k Lj^*_n(F'))
\]
is an isomorphism. Using the local global spectral sequence it suffices to prove that
\[
\pi_{s,*} R\text{Hom}_{X/\hat{G}}(F, F') \to \pi_{s,*} Rj_{s,*} R\text{Hom}_{X^\nu/Q}(\chi_n \otimes_k Lj^*_n(F), \chi_n \otimes_k Lj^*_n(F'))
\]
is an isomorphism. To do this we may assume that $X/\hat{G}$ is affine. Then we can check it on the generators $P_{-n,V}$ of $\mathcal{D}_n$ and finally we invoke (7.8).

Combining the equivalence (7.10) with the semi-orthogonal decomposition (7.8) we obtain a semi-orthogonal decomposition
\[
\mathcal{D}(X/\hat{G}) = \langle \mathcal{D}(X^{\nu}/Q) \mid n \in \mathbb{Z} \rangle.
\]
Considering suitable subset of the local generators one obtains in the same way a semi-orthogonal decomposition of \( \mathcal{D}(X/G)_\tau \). To be more precise consider the following set
\[
S = \{ (n, \mu) \in \mathbb{Z} \times A_Q \mid -\tilde{\chi}_n + \tilde{\mu} = \tilde{\tau} \}
\]
Let \( \prec \) be the partial ordering on \( S \) induced from the projection \( S \to \mathbb{Z} \), i.e. \( (n, \mu) \prec (n', \mu') \) if and only if \( n < n' \). Let \( \prec \) be a total ordering on \( S \) which refines \( \prec \). Then we have a semi-orthogonal decomposition
\[
\mathcal{D}(X/G)_\tau = \langle \mathcal{D}(X/Q)_\mu \mid (n, \mu) \in S \rangle.
\]
Combining this with the identification (7.5) yields (7.7).

\[\square\]

Remark 7.5. Even if \( A = 0 \) (and hence \( \mathcal{D}(X/G)_\tau = \mathcal{D}(X/G) \)), the group \( A_Q \) and the twisting characters \( \mu_i \) will generally be non-trivial in Propositions 7.3, 7.4.

Remark 7.6. Note that in Propositions 7.3, 7.4 we have \( \dim Q < \dim G \). Thus we have made genuine progress. By repeatedly applying Propositions 7.3, 7.4 we reduce to a semi-orthogonal decomposition of \( \mathcal{D}(X/G)_\tau \) involving a set of \( \mathcal{D}(X'/G')_{\tau'} \) such that \( X' \) has a \( T' \)-stable point for \( T' \) a maximal torus of \( G' \), thus justifying Remark 1.2.4 (and also making it more precise).

8. The quasi-symmetric case

In this section we refine the semi-orthogonal decomposition of \( \mathcal{D}(X/G) \) given in Proposition 1.2.2 in the quasi-symmetric case. In some cases the refined decomposition consists of (twisted) non-commutative crepant resolutions of certain quotient singularities for reductive groups.

8.1. Main result. Let \( W \) be a finite dimensional \( G \)-representation of dimension \( d \) such that \( X = W^\vee \). Let \((\beta_i)_{i=1}^d \in X(T)\) be the \( T \)-weights of \( W \). Throughout this section we assume that \( W \) is quasi-symmetric; i.e., for every line \( \ell \subset X(T)_\mathbb{R} \) through the origin we have \( \sum_{\beta_i \in \ell} \beta_i = 0 \).

Let \( \Delta \subset \mathbb{R}^n \) be a bounded closed convex polygon. For \( \varepsilon \in \mathbb{R}^n \) parallel to the linear space spanned by \( \Delta \) put
\[
\Delta_\varepsilon = \bigcup_{r > 0} \Delta \cap (r \varepsilon + \Delta),
\]
\[
\Delta_{\pm \varepsilon} = \Delta_\varepsilon \cap \Delta_{-\varepsilon}.
\]

We say that a \( W \)-invariant \( \varepsilon \in X(T)_\mathbb{R} \) is generic for \( \Delta \) if it parallel to \( \Delta \) but not parallel to any face of \( \Delta \). Note that such \( \varepsilon \) does not necessarily exist - for example there may be no non-zero \( W \)-invariant vectors at all. We shall say that \( \varepsilon \) is weakly generic for \( \Delta \) if it is parallel to \( \Delta \) but not parallel to faces of \( \Delta \) for which there exist non-parallel \( W \)-invariant vectors.

Let \( 0 \neq \lambda \in Y(T)^- \) and let \( A \) be a finite central subgroup of \( G^\lambda \) which acts trivially on \( X^\lambda = (W_\lambda)^\vee \). Fix \( \tau \in A \) and \( W_{G^\lambda} \)-invariant \( \varepsilon, \nu \in X(T)_\mathbb{R} \).

We denote \( \bar{T} = T/A \) and \( X(\bar{T})_\tau \) the inverse image of \( \tau \in X(A) \) under the natural projection map \( X(T) \to X(A) \) (see (7.3)), and we write \( X(\bar{T})^\lambda \) for the \( G^\lambda \)-dominant weights inside \( X(\bar{T})_\tau \).
Put
\[ \mathcal{L}^\xi_{\lambda, \nu, \tau} = X(T)^\lambda \cap (\nu - \tilde{\rho}_\lambda + (1/2)(\Sigma_\lambda + \tau), \]
\[ U^\xi_{\lambda, \nu, \tau} = \bigoplus_{\mu \in \mathcal{L}^\xi_{\lambda, \nu, \tau}} V_{G^\lambda}(\mu), \]
\[ A^\xi_{\lambda, \nu, \tau} = (\text{End} U^\xi_{\lambda, \nu, \tau} \otimes_k \text{Sym} W_\lambda)^{G^\lambda}. \]

As \( \lambda \neq 0 \) acts trivially on \( X^\lambda \) the latter does not have a \( T = T_{G^\lambda} \)-stable point. Since \( W_\lambda \) is also quasi-symmetric, we are in situation of Lemma 7.1(4). We denote by \( Q_\lambda \subset G^\lambda \) a pseudo-complement of the stabilizer subgroup \( \text{Stab}(X^\lambda) \subset G^\lambda \).

Recall the following definition from [ˇSVdB17a]:

**Definition 8.1.** We say that \( W \) is a **generic** \( G \)-representation if

1. \( X \) contains a point with closed orbit and trivial stabilizer.
2. \( X^s \subset X \) is the locus of points that satisfy (1) then \( \text{codim}(X - X^s, X) \geq 2. \)

We say that \( W \) is a pseudo-generic \( G \)-representation if the stabilizing subgroup \( \text{Stab}(X) \) of \( G \) is finite, and \( W \) is a generic \( G/\text{Stab}(X) \)-representation.

**Remark 8.2.** Let \( W, U \) be finite dimensional \( G \)-representations. Assume that \( A = \text{Stab} W \subset G \) is finite. We have \( (SW)^G = (SW)^{G/A} \), and \( (U \otimes SW)^G \cong (U^A \otimes SW)^{G/A} \). As such the results stated in [ˇSVdB17a] for generic representations extend trivially to pseudo-generic representations.

We will need a “crepant” version of Proposition 1.2.1. For the definition of twisted non-commutative resolution (twisted NCCR) we refer to [ˇSVdB17a] Definition 3.2.

**Proposition 8.3.** [ˇSVdB17a] Theorems 1.6.3, 1.6.4] We have \( \text{gl dim} \lambda^\xi_{\lambda, \nu, \tau} < \infty. \) Moreover, if \( W_\lambda \) is a pseudo-generic \( Q_\lambda \)-representation, \( \mathcal{L}^\xi_{\lambda, \nu, \tau} \neq \emptyset \) and

\[ X(T)^\lambda \cap (\nu - \tilde{\rho}_\lambda + (1/2)((\Sigma_\lambda + \tau)_{\pm \epsilon} - \Sigma_\lambda)) = \emptyset \]

then \( \lambda^\xi_{\lambda, \nu, \tau} \) is a twisted NCCR of \( (\text{Sym} W_\lambda)^{G^\lambda} \).

**Proof.** The first part follows by the proof of [ˇSVdB17a] Theorem 1.6.3]. To show that \( \lambda^\xi_{\lambda, \nu, \tau} \) is Cohen-Macaulay we can proceed as in the proof of [ˇSVdB17a] Theorem 1.6.4] since \( X^\lambda \) has a stable \( Q_\lambda \)-point (as \( W_\lambda \) is a pseudo-generic \( Q_\lambda \)-representation).

Then \( \lambda^\xi_{\lambda, \nu, \tau} \) is a twisted NCCR by Remark 8.2 and [ˇSVdB17a] Proposition 4.1.6].

We can now state the main result of this appendix (see [8.3] below for the proof).

**Proposition 8.4.** Let \( X \) have a \( T \)-stable point. There exist \( \lambda_i \in Y(T)^{-}, \) finite central subgroups \( A_i \) of \( G^\lambda \) acting trivially on \( X^\lambda \), \( \tau_i \in X(A_i) \), \( W_{G^\lambda} \)-invariant \( \nu_i, \epsilon_i \in X(T)_B \), such that \( D(X/G) \) has a semi-orthogonal decomposition \( D = \langle \ldots, D_{-2}, D_{-1}, D_0 \rangle \) with \( D_{-i} \cong D(\Lambda^\epsilon_{\lambda_i, \nu_i, \tau_i}) \). Moreover, we may assume \( D_0 \cong D(\Lambda^\epsilon_{0,0,0}) \), and that \( \epsilon_i \) is weakly generic for \( \Sigma_\lambda \).

Combining Propositions 8.3, 8.4] we thus obtain under some favourable conditions a semi-orthogonal decomposition of \( D(X/G) \) consisting of twisted NCCRs.
Corollary 8.5. If for every $\lambda \in Y(T)^-$ either $W_\lambda = \{0\}$ or $W_\lambda$ is a pseudo-generic $Q_\lambda$-representation and the condition (8.1) holds for all $W_{G^\lambda}$-invariant $\nu \in X(T)_\Sigma$ and for all $W_{G^\lambda}$-invariant $\varepsilon \in X(T)_\Sigma$ which are weakly generic for $\Sigma$, and all $\tau \in X(A)$ for an arbitrary finite central subgroup $A$ of $G^\lambda$, then $D(X/G)$ has a semi-orthogonal decomposition $D = \langle \ldots, D_{-2}, D_{-1}, D_0 \rangle$ with $D_{-i} \cong D(\Lambda_{i, \nu, \tau}^\lambda)$, and $\Lambda_{i, \nu, \tau}^\lambda$ is a twisted NCCR of $\lambda$-invariant $\Sigma$.8.2. Examples. Here we list some examples of quotient singularities for reductive groups for which Corollary 8.5 gives a semi-orthogonal decomposition such that its components are NCCRs of singularities of the same type. In the cases below one can verify (8.1) in a similar way as the analogous condition was verified in [SVdB17a].

8.2.1. Torus action. In the case of $G = T$ the condition (8.1) holds for every generic $\varepsilon \in X(T)_\Sigma$, and therefore also for every weakly generic $\varepsilon$ since the two notions coincide in this case. Considering also the pseudo-genericity of $W_\lambda$ we deduce the following proposition.

Proposition 8.6. Assume that on every line $\ell \subset X(T)_\Sigma$ through the origin on which lies a nonzero $\beta_i$ there lie at least two $\beta_i$ on each of its sides. Then the condition in the Corollary 8.5 is satisfied and thus $D(X/G)$ admits a semi-orthogonal decomposition consisting of NCCRs.

8.2.2. $SL_2$-action. Let $G = SL_2 = SL(V)$ for a 2-dimensional vector space $V$. Put $W = \bigoplus_{i=0}^s S^d V, \; c = \{|i | d_i = 0\}$, 

$$s(n) = \begin{cases} n + (n-2) + \cdots + 1 = \frac{(n+1)^2}{4} & \text{if } n \text{ is odd} \\ n + (n-2) + \cdots + 2 = \frac{n(n+2)}{4} & \text{if } n \text{ is even} \end{cases}$$

and $s = \sum_i s(d_i)$. Set $R = (\text{Sym} W)^G, \; M = \bigoplus_{0 \leq i \leq s/2-1} (\text{Sym} W \otimes V^i V)$. 

Proposition 8.7. (1) If $W$ is a sum of $k^c$ and one of the following representations

$$V, S^2V, V \oplus V, V \oplus S^2V, S^2V \oplus S^2V, S^3V, S^4V,$$

then $(\text{Sym} W)^G$ is a polynomial ring, and $D(X/G)$ has a semi-orthogonal decomposition $D = \langle \ldots, D_{-2}, D_{-1}, D_0 \rangle$, with $D_{-i} \cong D(k[x_1, \ldots, x_c])$ for $i > 0, \; D_0 \cong D(R)$.

(2) If $W$ is not as in the case (1) and if $s$ is odd then $D(X/G)$ has a semi-orthogonal decomposition $\langle \ldots, D_{-2}, D_{-1}, D_0 \rangle$ with $D_{-i} \cong D(k[x_1, \ldots, x_c])$ for $i > 0, \; D_0 \cong D(\text{End}_R(M))$.

Proof. We note that every representation of $SL_2$ is quasi-symmetric. Let us first assume that we are in the case (2). We have $\Sigma = \emptyset, s, t$. We want to verify the condition (8.1) for $\lambda = 0$. Note that $\varepsilon = 0$ and $A = 0$. As $s$ is odd, $W$ satisfies (8.1) (cf. [SVdB17a] Theorem 1.4.5 and its proof). Since $s$ is odd it also follows that $W$ is a generic $SL_\lambda$-representation. Moreover if $\lambda \neq 0$ then $W_\lambda$ is a sum of trivial representations and hence $\text{Stab}(W_\lambda) = G^\lambda$. Thus $Q_\lambda$ is the trivial group. So in particular $W_\lambda$ is $Q_\lambda$-generic for $\lambda \neq 0$. Since $Q_\lambda$ is the trivial group for $\lambda \neq 0$ we verify that $\Lambda_{i, \nu, \tau}^\lambda \cong \text{Sym} W_\lambda \cong k[x_1, \ldots, x_c]$ if $\Lambda_{i, \nu, \tau}^\lambda \neq 0$. 

If $W$ is as in $[\mathbf{H}]$ then it is well-known that $(\text{Sym} W)^G$ is a polynomial ring. Therefore $(P_i) \cong \mathcal{D}((\text{Sym} W)^G)$ is admissible in $\mathcal{D}(X/G)$, and thus we can set it to be equal to $\mathcal{D}_0$, and we can adjust the proof of Proposition $[\mathbf{H}, \S 6.1]$ to get as above $\mathcal{D}_{-i} \cong \langle \text{Sym} W, \lambda \rangle \cong k[x_1, \ldots, x_c]$ for $\lambda \neq 0$. \hfill $\square$

8.2.3. Determinantal varieties. Let $n < h$, $W = (V^{*})^{h} \oplus V^h$, $\dim V = n$, $G = \text{GL}(V)$, and let $Y_{n,h} = W \langle V/G \rangle$ be the variety of $h \times h$-matrices of rank $\leq n$. We denote by $\Lambda_j$ the NCCR of $Y_{j,h}$ given by $[\text{SVdB17a}, \S 5.2.2]$ (constructed earlier in $[\text{BLVdB11}, \text{DS14}]$). For convenience we set $\Lambda_0 := k$.

**Proposition 8.8.** Let $\mathcal{D} = \mathcal{D}(X/G)$. Then $\mathcal{D}$ has a semi-orthogonal decomposition $\langle \ldots, \mathcal{D}_{2}, \mathcal{D}_{-1}, \mathcal{D}_0 \rangle$ with $\mathcal{D}_{0} \cong \mathcal{D}(\Lambda_n)$, $\mathcal{D}_{-i} \cong \mathcal{D}(\Lambda_j)$ for some $j < n$.

**Proof.** Let us recall some relevant data from $[\text{SVdB17a}, \S 5]$. Let $L_i \in \mathcal{X}/(T)$ be given by $\text{diag}(z_1, \ldots, z_n) \to z_i$. The weights of $W = V^h \oplus (V^{*})^h$ are $(\pm L_i)_i$, each weight occurring with multiplicity $h$, and a system of positive roots is given by $(L_i - L_j)_i \geq j$.

The weights of $W_{\lambda}$ are of the form $(\pm L_i)_{i \in S}$ for some subset $S \subset \{1, \ldots, n\}$, each weight occurring with multiplicity $h$, and $Q_{\lambda}$ is isomorphic to $\text{GL}(V_{\lambda})$, where $V_{\lambda}$ is an $|S|$-dimensional vector space. Thus, $W_{\lambda}$ is a $Q_{\lambda}$-generic representation (see $[\text{SVdB17a}, \S 5.1]$). Note that none of the weights of $W$ belongs to the subspace of $\mathcal{X}(T)$ spanned by the roots. Note also that $\mathcal{X} = \sum L_i \in \mathcal{X}(T)$ is $W$-invariant and that the space of $W_{\lambda}$-invariant vectors is spanned by $\sum_{i \in S} L_i$. Thus, it is enough to see that $\sum_{i \in S} L_i$ satisfies $[\mathbf{S}]$ for $\lambda \in \mathcal{X}(T)^{-}$ in order to apply Corollary $8.5$.

Similarly as in the proof of $[\text{SVdB17a}, \S 5.2.2]$ we have for $W_{\lambda}$-invariant $\nu \in \mathcal{X}(T)$

$$\nu - \bar{\rho}_{\lambda} + (1/2)(\bar{\Sigma}_{\lambda})_{\pm \epsilon} =$$

$$\sum_{i \in T_{\lambda}^{+} \cup T_{\lambda}^{-}} r_i L_i - \sum_{i \in T_{\lambda}^{0}} (n - 2i + 1)/2 L_i + \left\{ \sum_{i \in T_{\lambda}^{0}} a_i L_i \mid a_i \in [-h/2, h/2] \right\} =$$

$$\nu - \bar{\rho}_{\lambda} + (1/2)\bar{\Sigma}_{\lambda},$$

which implies $[\mathbf{S}]$.

Moreover, from the previous paragraph it also follows that the components of the semi-orthogonal decomposition from Proposition $[\mathbf{S}]$ are in this case isomorphic to the NCCRs of $Y_{j,h}$, $1 \leq j \leq n$, or to $\mathcal{D}(k)$.

8.2.4. Pfaffian varieties. Let $2n < h$, $W = V^h$, where $V$ is a $2n$-dimensional vector space equipped with a non-degenerate skew-symmetric bilinear form, $G = \text{Sp}_{2n}(k)$, and let $Y_{2n,h} = W \langle V/G \rangle$ be the variety of skew-symmetric $h \times h$-matrices of rank $\leq 2n$. We denote by $\Lambda_j$ the NCCR of $Y_{2j,h}$ given by $[\text{SVdB17a}, \S 6.1.2]$. For convenience we set $\Lambda_0 := k$.

**Proposition 8.9.** If $h$ is odd then $\mathcal{D}(X/G)$ has a semi-orthogonal decomposition $\langle \ldots, \mathcal{D}_{2}, \mathcal{D}_{-1}, \mathcal{D}_0 \rangle$ with $\mathcal{D}_{0} \cong \mathcal{D}(\Lambda_n)$, $\mathcal{D}_{-i} \cong \mathcal{D}(\Lambda_j)$ for some $j < n$.

**Proof.** We recall some fragments of $[\text{SVdB17a}, \S 6.1]$. We assume that $(v_i)_i$ is a basis for $V$ such that the skew-symmetric form on $V$ is given by $\langle v_i, v_{i+n} \rangle = 1$, $\langle v_i, v_j \rangle = 0$ for $j \neq i \pm n$. Let $T \subset \text{Sp}(V)$ be the maximal torus $\{ \text{diag}(z_1, \ldots, z_n, z_1^{-1}, \ldots, z_n^{-1}) \}$ and let $L_i \in \mathcal{X}(T)$ be given by $(z_1, \ldots, z_n) \to z_i$. The weights of $W = V^h$ are
(±L_i)_j, each occurring with multiplicity h, and a system of positive roots is given by (L_i - L_j)_{k>j}, (2L_i), \bar{\rho} = nL_1 + (n - 1)L_2 + \cdots + L_n,
\Sigma = \{\sum_i a_i L_i \mid a_i \in [-h, h]\}.

For \lambda \in Y(T) and W_{G\lambda}-invariant \nu \in X(T)_R we thus have
\nu - \bar{\rho} + (1/2)\Sigma = \sum_{i \in T^\lambda \cup T^-} r_i L_i - \sum_{i \in T^\lambda} (n-1+i)L_i + \left\{\sum_{i \in T^0} a_i L_i \mid a_i \in [-h/2, h/2]\right\}

It easily follows that the boundary of this set does not intersect X(T) if h is odd, thus the condition \([5.11]\) holds.

Similarly as in the case of determinantal varieties, W_\lambda is Q_\lambda-generic, and here the semi-orthogonal decomposition consists of the NCCRs of Pfaffian varieties Y_{2k,h}, 1 \leq k \leq n, or D(k). □

8.3. Proof of Proposition 8.4.

8.3.1. Preliminaries. We remind the reader of our standing hypothesis that W is quasi-symmetric. In [63] (see [62, Remark 5.2.3]) we partitioned the set X(T)^+ according to the relative interiors of faces of −\bar{\rho} + r\Sigma, r \geq 1. However, in order to obtain a decomposition by NCCRs we need a finer decomposition of X(T)^+. As indicated in Proposition 8.3 the decomposition parts should be roughly given by slightly shifted faces of −\bar{\rho} + (1/2)\Sigma. To obtain such a decomposition we will inductively refine each face of −\bar{\rho} + r\Sigma. While in [5] we started with r \geq 1, we need here r > 1/2. The following lemma will ensure that this is indeed possible.

We note first that properties of the partition in [63] remain basically unchanged if we replace −\bar{\rho} + r\Sigma by \nu - \bar{\rho} + r\Sigma for a W-invariant \nu \in X(T)_R.

By replacing −\bar{\rho} in the right hand side of (7.2) by \nu - \bar{\rho} we obtain a minimal quadruple which we denote by (\nu, S^\nu_{\mu}) and also a corresponding one-parameter subgroup \lambda^\nu as in Lemma 5.2.1.2. We will omit the extra decoration (−)^\nu in case no confusion can arise.

The following lemma is an improved and slightly generalized version of Corollary 5.2.6 which holds because W is quasi-symmetric.

Lemma 8.10. Let \chi \in X(T)^+ be such that r^\nu_{\mu} > 1/2. If p > 0 and \mu = \chi + \beta_{i_1} + \cdots + \beta_{i_p}, where \{i_1, \ldots, i_p\} \subset \{1, \ldots, d\}, i_j \neq i_{j'} for j \neq j' and \langle \lambda^\delta, \beta_{i_j}\rangle > 0, then (r^\nu_{\mu}, |S^\nu_{\mu}|) < (r^\nu_{\chi}, |S^\nu_{\chi}|). Moreover, \langle \lambda^\nu, \chi \rangle < \langle \lambda^\nu, \mu^\nu \rangle.

Proof. For the first claim we proceed exactly as in the proof of [63, Theorem 1.6.1]. The second claim follows as the corresponding part in Corollary 5.2.6. □

Here we use notation introduced in [7]. For \lambda \in Y(T)^− and for W-invariant \nu \in X(T)_R and \tau \in A we denote
\mathcal{L}_{\lambda,\nu,\tau} = X(T)^\lambda \cap (\nu - \bar{\rho}_\lambda + r\Sigma_\lambda),
D_{\lambda,\nu,\tau}(X/G)_\tau = \langle P_{G^\lambda,\chi} \mid \chi \in \mathcal{L}_{\lambda,\nu,\tau}\rangle,
U_{\lambda,\nu,\tau} = \bigoplus_{\mu \in \mathcal{L}_{\lambda,\nu,\tau}} V_{G^\lambda}(\mu),
A_{\lambda,\nu,\tau} = (\text{End}(U_{\lambda,\nu,\tau}) \otimes_k \text{Sym} W_\lambda)^{G^\lambda}. 
so that in particular

\[ \mathcal{D}_{\lambda,r,\nu}(X/G)_\tau \cong \mathcal{D}(\Lambda_{\lambda,r,\nu,\tau}) \]

We will also use some specializations of these notations in case part of the data \( \lambda, r, \nu, \tau \) is omitted. If \( \lambda \) is omitted then we assume \( \lambda = 0 \). If \( r \) is omitted then we assume that \( r = 1/2 + \epsilon \) where \( \epsilon > 0 \) but arbitrarily small. For example with this convention we have

\[
\mathcal{L}_{\lambda,\nu,\tau} = X(\tilde{T})_\tau^+ \cap (\nu - \bar{\rho}_\lambda + (1/2)\bar{\Sigma}_\lambda), \\
\mathcal{L}_{\nu,\tau} = X(\tilde{T})_\tau^+ \cap (\nu - \bar{\rho} + (1/2)\bar{\Sigma}).
\]

In the other direction, to indicate, context we may also write \( (G, X, \lambda, r, \nu, \tau) \) instead of \( (\lambda, r, \nu, \tau) \), where we allow again \( r \) or \( \lambda \) to be omitted.

**Proposition 8.11.** [SVdB17a, Theorem 1.6.1] Assume \( r > 1/2 \). Then \( \text{gl dim } \Lambda_{r,\nu,\tau} < \infty \). Consequently, \( \mathcal{D}_{r,\nu}(X/G)_\tau \cong \mathcal{D}(\Lambda_{r,\nu,\tau}) \). In particular, (specializing to \( \lambda = 0 \) and \( r = 1/2 + \epsilon \)) \( \text{gl dim } \Lambda_{\nu,\tau} < \infty \) and \( \mathcal{D}_{\nu}(X/G)_\tau \cong \mathcal{D}(\Lambda_{\nu,\tau}) \).

**Lemma 8.12.** Let \( \nu \) be a \( W \)-invariant element of \( X(T)_R \). Using the partition \( (5.12) \) of \( X(T)^+ \), calculated with respect to \( \nu - \bar{\rho} + r\bar{\Sigma} \), \( r > 1/2 \) and using \( (r^*_\chi, S^*_\chi) \), the analogues of Propositions \( 7.1, \, 7.2 \) hold.

**Proof.** Using Lemma 8.10 in place of Corollary 5.2.6 and Proposition 8.11 it is easy to check that the proofs of the semi-orthogonal decompositions in \( [6] \) carry over with the above partition of \( X(T)^+ \), replacing \( \Lambda_{<j}, \mathcal{D}_{<j} \), \( \mathcal{D}_{j} \) by their shifted counterparts \( \Lambda_{<j,\nu}, \mathcal{D}_{<j,\nu}, \mathcal{D}_{j,\nu} \). Consequently, the same holds true also for \( \Lambda_{<j,\nu,\tau}, \mathcal{D}_{<j,\nu,\tau}, \mathcal{D}_{j,\nu,\tau} \) (see proof of Proposition 7.2). \( \square \)

If \( K \) is a connected normal subgroup of \( G \), and \( Q \) is a chosen pseudo-complement, then we denote (as in the proof of Proposition 7.2) by \( \tilde{T} = T_K \times T_Q \) a maximal torus of \( \tilde{G} = K \times Q \), such that \( \tilde{T} \to T \subset G \) (under the multiplication map). Let us denote by \( (\nu_K, \nu_Q) \) the image of \( \nu \in X(T) \) in \( X(\tilde{T}) \).

**Lemma 8.13.** Let \( \nu \in X(T)_R \) be \( W \)-invariant. Assume that there is a non-trivial connected subgroup \( K \) of \( G \) acting trivially on \( X \). Let \( Q \) be a pseudo-complement of \( K \) in \( G \). Then there exist a \( W_Q \)-invariant \( \nu_Q \in X(T_Q)_R \), a finite central group \( \Lambda_Q \) of \( Q \) acting trivially on \( X \), and \( \tau_Q \in X(A_Q) \) such that

\[
\mathcal{L}_{\lambda,\tau_Q} \cong \mathcal{L}_{\lambda,\nu_K,\nu_Q,\tau_Q}
\]

via the natural map \( X(\tilde{T})_\tau \to X(T) \to X(\tilde{T})_\tau \to X(T_Q) \).

**Proof.** The proof is similar to the proof of Proposition 7.3, additionally noting that \( -\bar{\rho} \) decomposes as \( (-\bar{\rho}_K, -\bar{\rho}_Q), \beta_i \) as \( (0, \beta_i) \), \( \nu \) as \( (\nu_Q, \nu_K) \), and \( \tau_Q \in X(A_Q) \) satisfies \( \bar{\tau}_Q + \bar{\nu}_K - \bar{\rho}_K = \bar{\tau} \). \( \square \)

8.3.2. **Proof.** The proof is in two steps. We first decompose \( \mathcal{D}(X/G) \) such that its components are isomorphic to \( \mathcal{D}(\Lambda_{\lambda,\nu,\tau}) \), and then we decompose this further with components isomorphic to \( \mathcal{D}(\Lambda_{\lambda,\nu,\tau}) \).

**Lemma 8.14.** Let \( X \) have a \( T \)-stable point. There exist \( \lambda_i \in Y(T)^- \), finite central subgroups \( A_i \) of \( G^{\lambda_i} \) acting trivially on \( X^{\lambda_i} \), \( \tau_i \in X(A_i) \), \( W_{G^{\lambda_i}} \)-invariant \( \nu_i \in X(T)_R \) such that \( \mathcal{D} = \mathcal{D}(X/G) \) has a semi-orthogonal decomposition \( \mathcal{D} = \langle \ldots, D_{-2}, D_{-1}, D_0 \rangle \) with \( D_{-1} \cong \mathcal{D}(\Lambda_{\lambda,\nu,\tau}) \).
Proof. We decompose $\mathcal{D}$ according to faces of $-\bar{p} + r\Sigma$ assuming $r_j > 1/2$. By Lemmas 8.12, 8.13 and (7.6) we have $\mathcal{D}_{-i} \cong \mathcal{D}_{r_j, (\nu_i)_{Q_{\lambda_j}}} (X^{\lambda_j}/Q_{\lambda_j})_{r_{Q_{\lambda_j}}}$. 

As $\dim X^{\lambda_j} < \dim X$, $\dim Q_{\lambda_j} < \dim G$, $r_j > 1/2$ we can decompose $\mathcal{D}_{-i}$ further. Note that in finitely many steps (as $\mathcal{L}_{r,\nu,\tau}$ is finite) we reach the situation when every component of the decomposition is of the form $\langle P_\chi \mid \chi \in \mathcal{L}_{\lambda,\nu,\tau} \rangle$ for some $\lambda \in Y(T)^{-}$, $W_{G,\lambda}$-invariant $\nu \in X(T)_R$ and $\tau \in X(A)$ for a finite central subgroup $A$ of $G^\lambda$ acting trivially on $X^\lambda$ by Lemma 8.16 below (and the fact that for $r = 1/2 + \epsilon$ we have by definition $\mathcal{L}_{\lambda,\nu,\tau} = \mathcal{L}_{\lambda,\nu,\tau}$).

We now proceed to decompose $\mathcal{D}_{\lambda,\nu}(X/G)_\tau \cong \mathcal{D}(\Lambda_{\lambda,\nu,\tau})$ further.

**Lemma 8.15.** There exist $\lambda_0 = \lambda$, $\lambda_i \in Y(T)^{-}$, $W_{G,\lambda}$-invariant $\nu_i$, $W_{G,\lambda}$-invariant $\varepsilon_i \in X(T)_R$ which are weakly generic for $\Sigma_{\lambda}$, finite central subgroups $A_i$ of $G^\lambda$ acting trivially on $X^{\lambda_i}$, $\tau_i \in X(A_i)$ such that $\mathcal{D} = \langle \mathcal{D}_{-i} \rangle_{\lambda_i}$ has a semi-orthogonal decomposition $\mathcal{D} = \langle \mathcal{D}_{-k, \ldots, -1, D_0} \rangle$ with $\mathcal{D}_{-i} \cong \mathcal{D}(\Lambda_{\lambda_i}^{r_i, \nu_i, \tau_i})$ for $i \geq 0$.

Proof. We choose a $W_{G,\lambda}$-invariant $\varepsilon \in X(T)_R$ weakly generic for $\Sigma_{\lambda}$ and small $a > 0$ such that

$$X(\bar{T})^{\lambda} \cap (\nu - \bar{p} + (1/2)\Sigma_{\lambda}) = X(\bar{T})^{\lambda} \cap (\nu - \bar{p} + a\varepsilon + (1/2)\Sigma_{\lambda})$$

and

$$(8.3) \quad \mathcal{L}_{\lambda,\nu,\tau} = X(\bar{T})^{\lambda} \cap (\nu - \bar{p} + a\varepsilon + r'\Sigma_{\lambda})$$

for some $r' > 1/2$. We take $\delta = \nu + a\varepsilon$, and let $\nu_Q, \tau_Q$ be as in Lemma 8.13 and partition $X(T(Q_{\lambda}))^+$ accordingly. Due to (8.3) and Lemma 8.12 $\mathcal{L}_{\lambda,\nu,\tau} \cong \cup_{l \leq k} F_i$ and there exists $k \geq 0$ such that $\mathcal{L}_{\lambda,\nu,\tau} \cup_{l \leq k} F_i = \mathcal{L}_{\lambda,\nu,\tau}$. We set $\varepsilon_0 = \varepsilon$.

As in the second paragraph of the proof of Lemma 8.14 we can decompose $\langle P_\chi \mid \chi \in F_i \rangle$ further, until the components are isomorphic to $\mathcal{D}_{\lambda,\nu}(X/G)_\tau$ for some $\lambda \in Y(T)^{-}$, $W_{G,\lambda}$-invariant $\nu \in X(T)_R$ and $\tau \in X(A)$ for a finite central subgroup $A$ of $G^\lambda$ acting trivially on $X^\lambda$. Now we can repeat the first part of this proof and decompose $\mathcal{D}_{\lambda,\nu}(X/G)_\tau$ further. We get the desired decomposition by invoking Lemma 8.16 below.

We have used the following technical lemma.

**Lemma 8.16.** Let $\lambda' \in Y(T)^{-}$, $\lambda'' \in Y(T_{Q_{\lambda'}})^{-}$, let $\nu' \in X(T_{Q_{\lambda'}})$ be $W_{G,\lambda''}$-invariant, and let $A'$ be a finite central subgroup of $(Q_{\lambda'})^{\lambda''}$ acting trivially on $(X^{\lambda'})^{\lambda''}$, $\tau' \in X(A')$. There exist $\lambda \in Y(T)^{-}$, $W_{G,\lambda}$-invariant $\nu \in X(T)_R$ and $\tau \in X(A)$ for a finite central subgroup $A$ of $G^\lambda$ acting trivially on $X^\lambda$, $\tau \in X(A)$, such that

$$\mathcal{L}_{Q_{\lambda'}, X^{\lambda'}, X^{\lambda'}, r, \nu', \tau'} \cong \mathcal{L}_{\lambda, \nu, \tau},$$

$$\mathcal{D}_{Q_{\lambda'}, X^{\lambda'}, X^{\lambda'}, r, \nu'} (X^{\lambda'/Q_{\lambda'}})^+ \cong \mathcal{D}_{\lambda, \nu, \tau} (X/G)_\tau \cong \mathcal{D}_{r, \nu_Q} (X^{\lambda'/Q_{\lambda'}})_r.$$

Proof. It is easy to check using Lemma 8.13 that we can take $\lambda = a(\lambda' + b\lambda'')$ for small $b \in Q, a \in \mathbb{N}$ such that $\lambda \in Y(T)^{-}$.

**Proof of Proposition 8.4.** It suffices to combine Lemma 8.14 with Lemma 8.15.
