(Dated: June 10, 2014)

We study gravitational theories with a cosmological constant and the Gauss-Bonnet curvature squared term and analyze the possibility of de Sitter expanding spacetime with a constant internal space. We find that there are two branches of the de Sitter solutions: Both the curvature of the internal space and the cosmological constant are (1) positive and (2) negative. From the stability analysis, we show that the de Sitter solution of the case (1) is unstable, while that in the case (2) is stable. Namely de Sitter solution in the present system is stable if the cosmological constant is negative. We extend our analysis to the gravitational theories with higher-order Lovelock curvature terms. Although the existence and the stability of the de Sitter solutions are very complicated and highly depend on the coupling constants, there exist stable de Sitter solutions similar to the case (2). We also find de Sitter solutions with Hubble scale much smaller than the scale of a cosmological constant, which may explain a discrepancy between an inflation energy scale and the Planck scale.

PACS numbers:

I. INTRODUCTION

It is now commonly believed that there is an inflationary epoch of the early stage of the evolution of our universe \cite{1, 2}. This has been confirmed by the observation of the density fluctuation of the universe \cite{3, 4}. There is also a strong evidence that the present universe exhibits accelerating expansion. These facts prompt us to build cosmological models with accelerating phases. One may achieve this goal by introducing inflation with suitable potential. However it is more desirable if we can derive such models from the first principle or fundamental theory of particle physics without artificial assumptions. The most promising candidate of such a fundamental theory is the ten-dimensional superstring or eleven-dimensional M theory. However, it has been well known that an accelerating universe is difficult to realize for such theories, because there exists the so-called “no-go theorem” \cite{9}, which forbids accelerated expanding spacetime solutions if an internal space is a time-independent non-singular compact manifold without boundary.

Breaking some of the assumptions in the theorem, we can look for a natural inflationary scenario. One possibility is the brane inflation models \cite{10, 11}, in which we assume test branes and do not take into account the back reactions. Another is the S-brane solutions \cite{12}, in which temporal acceleration is possible but unfortunately big enough e-folding and/or long enough expansion was not obtained \cite{13}.

This suggests that the low-energy effective theory which is given by supergravity should have some modification of either the gravity side or matter side of the Einstein equation. A simple extension would be to introduce the cosmological constant, which must be extremely tiny to account for the current observation. From the supergravity point of view, this is not desirable because it is not natural to introduce such a tiny cosmological constant. Fortunately it is known that there are higher-order modifications to the low-energy gravitational action in superstrings. The leading corrections are given by the Gauss-Bonnet (GB) terms in heterotic string \cite{14, 15}. The effects of such terms have been studied in several papers, and interesting results are obtained that the inflationary universe is possible \cite{14, 16}, but some refinement was necessary to achieve enough inflation. Constraints on such models are also discussed in \cite{20}, where it was shown for flux compactification it is not possible to obtain de Sitter solutions. Earlier references on related subjects include \cite{21, 22, 23}.

In these works, no cosmological constant was considered. Recently it has been argued that when the curvature of the extra dimensional space is negative and there is a cosmological constant, one obtains solutions in which both the volume of the extra dimension and expansion rate of the four-dimensional spacetime tends to a constant \cite{30}. Stability of the obtained solutions is also examined. Naively we expect that there is no cosmological constant in the effective low-energy theories of superstrings, but its existence is not excluded. For example, it is known that type IIA theories have a 10-form whose expectation value may give rise to such a cosmological constant \cite{31}. Other possible sources include generation of such a term at one-loop in non-supersymmetric
heterotic string $^{32}$. There are also various forms in superstrings which could produce similar terms. So this is an interesting possibility and the search for cosmological solutions in the theory deserves further study.

When these forms get expectation values in superstring theories, they typically produce negative cosmological constant. This is also compatible with supersymmetry. As we discuss below, it is precisely when we have the negative cosmological constant that we find stable (de Sitter spacetime) $\times$ (maximally symmetric space of constant size). So our following solutions would be naturally realized in superstring theories. However, we should note that though the theories we consider are well motivated by heterotic string, there are some differences like neglecting dilaton field for simplicity. Also in any higher-dimensional theories including superstrings, it is always an important issue how to stabilize the moduli after compactification. We do not address this difficult question in this paper though we examine the stability of the obtained solutions against small perturbations in the overall sizes of four-dimensional spacetime and extra dimensions. Thus our stability does not guarantee that the solutions are stable in all directions, but if they are unstable in our analysis, they do not give interesting solutions.

In this paper we study whether it is possible to obtain solutions with de Sitter expansion of the four-dimensional spacetime and static internal space within the theories with such higher-order terms and a cosmological constant. It was stated in $^{30}$ that for a wide range of parameters (cosmological constant, Einstein and GB term coefficients) it is verified numerically that there are solutions of this type, but the details are not clear including the question of for what range of parameters this type of solutions are possible. We intend to extend this work to include a comprehensive scan of the parameter space as well as higher order Lovelock terms: We exhaust all possible such solutions for arbitrary signs of cosmological constant and signatures of the (constant) curvatures of the internal spaces. We do this first for theories with GB term, but extend the analysis to the effects of further higher-order Lovelock gravity. We also examine the stability of the obtained solutions. What is most interesting is that we find that such solutions exist even for negative cosmological constant provided that the curvature of the internal space is negative. Moreover we can also have such solutions for positive cosmological constant but they are unstable in general, and those solutions for negative cosmological constant give stable solutions. We also find that this tendency of the existence of the solutions and stability persist in the presence of the higher order terms. Note that these solutions are quite different from those in the Einstein theory with a cosmological constant, where such solutions exist only for positive cosmological constant.

We should note that there are similar claims that modified gravity with a negative cosmological constant can have a positive effective cosmological constant $^{33}$ based on $^{34}$. In the latter paper $^{34}$, in order to avoid eternal acceleration, a negative cosmological constant is introduced together with quintessence scalar field which has positive potential and gives positive contribution to the cosmological constant. This scalar degrees of freedom is interpreted as arising from the $f(R)$ gravity, which produces such scalar with exponential “cosmological term” in $^{33}$. In this view, the negative cosmological constant is cancelled by the scalar potential even though it appears that one considers modified gravity. Our mechanism is different from this in that we do not introduce a positive potential (or terms which can be rewritten as a potential). In another work $^{35}$, Wheeler-De Wit equation was studied semiclassically with a similar result.

This paper is organized as follows: In Sec. III we begin with the Einstein-Gauss-Bonnet theory with a cosmological constant. First we present our basic equations in this theory. For comparison, we summarize solutions of accelerating universe of the form (de Sitter spacetime) $\times$ (maximally symmetric space) in the Einstein gravity with a cosmological constant. Then in the present theory with GB term, we find solutions and study their stability. We then proceed to the study of the effects of higher Lovelock gravity in Sec. IV. We give the basic equations for the above spacetime in subsection IIIA the equations for perturbation in subsection IIIB and give solutions with the de Sitter spacetime being Minkowski in subsection IIIC. We then examine the stability of the solutions, and determine the region of parameters $\alpha_3$ and $\alpha_4$ for the stable Minkowski solutions in subsection III D. In Sec. IV we discuss the solutions of the form (de Sitter spacetime) $\times$ (maximally symmetric space of constant size) including the effects of higher-order Lovelock gravity. Sec. V is devoted to our conclusion.

II. EINSTEIN-GAUSS-BONNET SYSTEM WITH A COSMOLOGICAL CONSTANT

A. Field equations

We consider the following low-energy effective action for the heterotic string with a cosmological constant $\Lambda$:

$$S = \frac{1}{2\kappa_D^2} \int d^D x \sqrt{-g} \left[ R - 2\Lambda + \alpha_2 R_{\text{GB}}^2 \right],$$

(2.1)

where $\kappa_D^2$ is a $D$-dimensional gravitational constant, $\alpha_2 = \alpha'/8$ is a numerical coefficient given in terms of the Regge slope parameter, and $R_{\text{GB}}^2 = R_{\mu\nu\rho\sigma} R^{\mu\nu\rho\sigma} - 4 R_{\mu\nu} R^{\mu\nu} + R^2$ is the GB correction. Here the two-form and gauge fields (and their higher order terms) are dropped because setting them to zero is consistent with field equations. We also neglect dilaton for simplicity.
Let us consider the metric in $D$-dimensional space,
\[ ds_D^2 = -e^{2u_0(t)}dt^2 + e^{2u_1(t)}ds_p^2 + e^{2u_2(t)}ds_q^2, \]
where $D = 1 + p + q$. The external $p$-dimensional and internal $q$-dimensional spaces ($ds_p^2$ and $ds_q^2$) are chosen to be maximally symmetric, with the signature of the curvature given by $\sigma_p$ and $\sigma_q$, respectively. Though we are mainly concerned with flat external space ($\sigma_p = 0$) in this paper, it may be useful to give field equations for more general case.

The Ricci scalar and the GB correction term are given by
\[ R = e^{-2u_0} \left[ p_1 A_p + q_1 A_q - 2 \left( p_1 \dot{u}_1^2 + p q \dot{u}_1 \dot{u}_2 + q_1 \dot{u}_2^2 \right) \right] \]
\[ R_{GB}^2 = e^{-4u_0} \left\{ p_3 A_p^2 + 2 p_1 q_1 A_p A_q + q_3 A_q^2 + 4 \dot{u}_1 \dot{u}_2 (p q_2 A_p + p q_2 A_q) + 4 p_1 q_1 \dot{u}_1^2 \dot{u}_2^2 + 4 p X \left[ (p - 1) A_p + q_1 A_q + 2 (p - 1) q \dot{u}_1 \dot{u}_2 + 4 q Y \left[ p_1 A_p + (q - 1) A_q + 2 p (q - 1) \dot{u}_1 \dot{u}_2 \right] \right] \right\}, \]
where
\[ A_p := \dot{u}_1^2 + \sigma_p e^{2(u_0 - u_1)} , \quad A_q := \dot{u}_2^2 + \sigma_q e^{2(u_0 - u_2)}, \]
\[ X := \dot{u}_1 - \dot{u}_0 \dot{u}_1 + \dot{u}_2^2 , \quad Y := \dot{u}_2 - \dot{u}_0 \dot{u}_2 + \dot{u}_2^2 . \]
We have also used the following abbreviation:
\[ (k - \ell)_m := (k - \ell)(k - \ell - 1)(k - \ell - 2) \cdots (k - m), \]
where $k, \ell, m$ are integer numbers with $k > \ell$, $k > m$ and $\ell < m$.

Now the field equations are
\[ F := F_1 + F_2 = 0, \]
\[ F^{(p)} := f_1^{(p)} + f_2^{(p)} + X \left( g_1^{(p)} + g_2^{(p)} \right) + Y \left( h_1^{(p)} + h_2^{(p)} \right) = 0, \]
\[ F^{(q)} := f_1^{(q)} + f_2^{(q)} + Y \left( g_1^{(q)} + g_2^{(q)} \right) + X \left( h_1^{(q)} + h_2^{(q)} \right) = 0, \]
where
\[ F_1 = p_1 A_p + q_1 A_q + 2 p q \dot{u}_1 \dot{u}_2 - 2 \Lambda e^{2u_0}, \]
\[ f_1^{(p)} = (p - 1) A_p + q_1 A_q + 2 (p - 1) q \dot{u}_1 \dot{u}_2 - 2 \Lambda e^{2u_0}, \quad f_1^{(q)} = p_1 A_p + (q - 1) A_q + 2 p (q - 1) \dot{u}_1 \dot{u}_2 - 2 \Lambda e^{2u_0}, \]
\[ g_1^{(p)} = 2 (p - 1), \quad g_1^{(q)} = 2 (q - 1), \quad h_1^{(p)} = 2 q, \quad h_1^{(q)} = 2 p, \]
and
\[ F_2 = \alpha_2 e^{-2u_0} \left\{ p_3 A_p^2 + 2 p_1 q_1 A_p A_q + q_3 A_q^2 + 4 \left( p q_2 A_p + p q_2 A_q + p_1 q_1 \dot{u}_1 \dot{u}_2 \right) \dot{u}_1 \dot{u}_2 \right\}, \]
\[ f_2^{(p)} = \alpha_2 e^{-2u_0} \left\{ (p - 1) A_p^2 + 2 (p - 1) q_1 A_p A_q + q_3 A_q^2 + 4 \left( (p - 1) q_2 A_p + (p - 1) q_2 A_q + (p - 1) \dot{u}_1 \dot{u}_2 \right) \dot{u}_1 \dot{u}_2 \right\}, \]
\[ f_2^{(q)} = \alpha_2 e^{-2u_0} \left\{ p_3 A_p^2 + 2 p_1 (q - 1) A_p A_q + (q - 1) A_q^2 + 4 \left( p (q - 1) A_p + p (q - 1) A_q + p_1 (q - 1) \dot{u}_1 \dot{u}_2 \right) \dot{u}_1 \dot{u}_2 \right\}, \]
\[ g_2^{(p)} = 4 (p - 1) \alpha_2 e^{-2u_0} \left\{ (p - 2) A_p A_q + q_1 A_q + 2 (p - 2) q \dot{u}_1 \dot{u}_2 \right\}, \]
\[ g_2^{(q)} = 4 (q - 1) \alpha_2 e^{-2u_0} \left\{ p_1 A_p + (q - 2) A_q + 2 p (q - 2) \dot{u}_1 \dot{u}_2 \right\}, \]
\[ h_2^{(p)} = 4 q \alpha_2 e^{-2u_0} \left\{ (p - 1) A_p + (q - 1) A_q + 2 (p - 1) q \dot{u}_1 \dot{u}_2 \right\}, \]
\[ h_2^{(q)} = 4 p \alpha_2 e^{-2u_0} \left\{ (p - 1) A_p + (q - 1) A_q + 2 (p - 1) \dot{u}_1 \dot{u}_2 \right\}. \]

The basic relations, Eqs. (2.7) - (2.11), are not all independent as they satisfy
\[ \dot{F} + (p \dot{u}_1 + q \dot{u}_2 - 2 \dot{u}_0) F = p \dot{u}_1 F^{(p)} + q \dot{u}_2 F^{(q)}. \]

Here we normalize the variables by $\alpha_2$ such that $\dot{A}_q = \alpha_2 A_q$, $\dot{\Lambda} = \alpha_2 \Lambda$ and $\ldot = t/\sqrt{\alpha_2}$. In what follows, we drop a tild for brevity.
B. Solutions of Accelerating Universe

In this section, we solve the equations and provide an accelerating universe with a constant internal space. Thus

\[ \dot{u}_1 = H, \quad \dot{u}_2 = 0. \]  \tag{2.13}

We choose the time coordinate as \( u_0 = 0 \) and take the Hubble parameter \( H \) to be constant and the curvature of external space to be zero (\( \sigma_p = 0 \)). The latter condition in \( 2.13 \) means that \( A_q \) is also constant. Then the basic equations turn to be algebraic:

\[
-2\Lambda + p_1H^2 + q_1A_q + p_3H^4 + 2p_1q_1H^2A_q + q_3A_q^2 = 0, \\
-2\Lambda + p(p + 1)H^2 + (q - 1)_2A_q + (p + 1)_2H^4 + 2p(p + 1)(q - 1)_2H^2A_q + (q - 1)_4A_q^2 = 0. \tag{2.14}
\]

Usually, for a given cosmological constant \( \Lambda \), we obtain \( H^2 \) and \( A_q \) by solving these coupled quadratic equations. There is a simpler way to find solutions in our case: We can solve the equations for \( H^2 \) and \( \Lambda \) for given \( A_q \), which are just a single quadratic (or linear) equation in \( H^2 \) and a linear equation in \( \Lambda \):

\[
2p_2H^4 + pH^2[1 - 2(q - 1)(p - q + 1)A_q] - (q - 1)A_q[1 + 2(q - 2)_3A_q] = 0, \tag{2.15}
\]

\[
2\Lambda = p_3H^4 + p_1H^2(1 + 2q_1A_q) + q_1A_q[1 + (q - 2)_3A_q]. \tag{2.16}
\]

The stability analysis, which we will show the detail later, gives two eigenvalues of perturbations:

\[
\omega_\pm = \frac{H}{2} \left[ -(p + q - 1) \pm \sqrt{(p + q - 1)^2 + 8p} \right], \tag{2.18}
\]

one of which is always positive, giving an instability of this solution. There is no stable de Sitter solution.

Now let us discuss our model with the GB term. When \( q = 1 \), \( H = 0 \) is a trivial solution. Since \( \sigma_q = 0 \), it is locally a Minkowski spacetime. To have a real solution for \( H \), \( H^2 \) has to be real and positive. For \( q \geq 2 \), the possibly positive solution is

\[
H^2 = \frac{1}{4p_2} \left\{ -p[1 - 2(q - 1)(p - q + 1)A_q] \\
+ \left[ p^2[1 - 2(q - 1)(p - q + 1)A_q]^2 + 8p_2(q - 1)A_q[1 + 2(q - 2)_3A_q] \right]^{1/2} \right\}. \tag{2.19}
\]

It is now easy to see that the condition for the existence of the real positive solutions of \( H^2 \) is \( A_q[1 + 2(q - 2)_3A_q] \geq 0 \), which gives either \( A_q \geq 0 \), or

\[
A_q \leq A_q^{(M)} := -\frac{1}{2(q - 2)_3}, \tag{2.20}
\]

when \( q \geq 4 \). We call the former and latter cases the branch (1) and the branch (2), respectively. For \( q = 2 \) or 3, we have only the branch (1) with \( A_q \geq 0 \).

The cosmological constant is given by Eq. \( 2.15 \). This is one parameter (\( A_q \)) family of solutions.

Let us show some example in the case of \( p = 3, q = 6 \) in Figs. 1 and 2. Fig. 1 shows the Hubble expansion parameter square \( H^2 \) in terms of \( A_6 \), which is the solution of Eq. \( 2.15 \), while Fig. 2 gives \( H^2 \) and \( A_6 \) in terms of a cosmological constant given by \( 2.16 \).

The cosmological constant is always positive for the branch (1) solutions with \( A_q \geq 0 \). On the other hand,
\[ H^2 = \frac{A_6}{-\frac{q_1}{8(q-2)^2}}, \]

which is always negative. Here the equality corresponds to the Minkowski spacetime \((H = 0)\) with negative \(A_q^{(M)}\). It is remarkable that we have de Sitter solution even for a negative cosmological constant. We emphasize that this becomes possible due to the negative \(A_q\) and the existence of the GB term.

**C. Stability of Accelerating Universe**

Next we study the stability of the above solutions against small perturbations in the size of the spaces. Unless they are stable in these directions, they do not give interesting solutions. Choosing the time coordinate as \(u_0 = 0\) and perturbing the variables around the background solution \((H, A_q)\) with \(\Lambda\), given by Eqs. (2.15) and (2.16), as

\[ u_1(t) = Ht + \xi(t), \]
\[ u_2(t) = u_2^{(0)} + \eta(t), \]

where \(u_2^{(0)}\) is a constant and satisfies \(A_q = \sigma_q e^{-2u_2^{(0)}}\), we obtain the perturbation equations from our basic equations (2.7)-(2.9):

\[ P \dot{\xi} + Q \dot{\eta} + R \eta = 0, \]
\[ J \ddot{\xi} + K \ddot{\eta} + L \dot{\xi} + M \dot{\eta} + N \eta = 0, \]
\[ S \dddot{\xi} + T \dddot{\eta} + U \dot{\xi} + V \dot{\eta} + W \eta = 0, \]

where

\[ P : = p_1 H X, \]
\[ Q : = pq H Y, \]
\[ R : = -pq H^2 Y, \]
\[ J : = (p-1) X, \]
\[ K : = q Y, \]
\[ L : = p_1 H X, \]
\[ M : = (p-1)q H Y, \]
\[ N : = -pq H^2 Y, \]
\[ S : = p Y, \]
\[ T : = \frac{p H^2}{A_q} Y, \]
\[ U : = (p+1)q H Y, \]
\[ V : = \frac{p^2 H^3}{A_q} Y, \]
\[ W : = -(q-1)_2 A_q Z, \]

with

\[ X : = 1 + 2[(p-2)H^2 + q_1 A_q], \]
\[ Y : = 1 + 2[(p-1)_2 H^2 + (q-1)_2 A_q], \]
\[ Z : = 1 + 2[p(p+1)H^2 + (q-3)_4 A_q]. \]

Here we have used the equation for the background solution (2.15).

Eq. (2.24) is derived from Eq. (2.23), which is guaranteed by the Bianchi identity (2.12). Hence the independent equations are Eqs. (2.23) and (2.25). Eliminating \(\dot{\xi}\) by use of Eq. (2.23), we find the equation for \(\eta\) as

\[ \ddot{\eta} + p H \dot{\eta} + C = 0, \]

where

\[ C : = \frac{P W - R U}{P T - S Q} \]
\[ = \frac{A_q [(p+1)_0 q H^2 Y^2 - (p-1)(q-1)_2 A_q X Z]}{p Y [(p-1)_2 H^2 X - q A_q Y]} \].
To analyze the stability, we set
\[ \eta = \eta_0 e^{\omega t}, \]  
and find a quadratic equation for the eigenvalue \( \omega \):
\[ \omega^2 + pH \omega + C = 0, \]
whose solutions are given by
\[ \omega = \omega_{\pm} := \frac{1}{2} \left( -pH \pm \sqrt{p^2H^2 - 4C} \right) \]
\[ (2.33) \]
If both eigenvalues \( \omega_{\pm} \) are negative, i.e.,
\[ p^2H^2 - 4C \geq 0 \quad \text{and} \quad C > 0, \]
\[ (2.34) \]
or they are complex conjugates of each other with negative real part (guaranteed by \( pH > 0 \)), i.e.,
\[ p^2H^2 - 4C < 0, \]
\[ (2.35) \]
the solution for the expanding universe \((H > 0)\) is stable. Hence we conclude the expanding universe is stable if \( C > 0 \).

Using the background solutions, we have studied their stability. For \( q = 1 \), we have only Minkowski spacetime. No perturbation is possible. So we proceed to the case of \( q \geq 2 \).

First, we show one example of the eigenvalues \( \omega \) for the case of \( p = 3 \) and \( q = 6 \) in Fig. 3.

FIG. 3: The eigenvalues \( \omega_{\pm} \) and Re (\( \omega \)) in terms of \( A_b \). The stable solution \((A_b < -1/24)\) has two real negative or a positive real part of two complex conjugate eigenvalues, which are shown by the green solid or dashed curves, respectively. The unstable solution \((A_b > 0)\) has one real positive and one negative eigenvalues, which are shown by the red and blue solid curves, respectively.

For other dimensions, we also find similar results. The solution \( H^2 \) with positive \( A_q \) is unstable because the perturbations have always one positive eigenvalue \( \omega_{+} \). On the other hand, the solution \( H^2 \) with negative \( A_q (\leq A_q^{(M)}) \) is stable.

Since the results in Fig. 3 is obtained by numerical calculation only for \( p = 3, q = 6 \), it is worth showing the results for general \( p \) and \( q \) in some simple limit. The Minkowski spacetime \((H = 0)\) gives the boundary of a set of the solutions. Hence it may be important to analyze solutions near the Minkowski spacetime, which are given by
\[ H^2 \approx \begin{cases} \frac{q-1}{p} A_q - \frac{(q-1)(q-1)(2q-3) + O(H^2)}{pq(q-1)} & \text{for branch}(1)(A_q \geq 0) \\ \frac{(q-1)(q-1)(2q-3) + O(H^2)}{2pq(q-2)^2} + O(H^2) & \text{for branch}(2)(A_q \leq A_q^{(M)}) \end{cases} \]

assuming \( H^2 \ll 1 \).

Using these solutions, we find
\[ C = \begin{cases} -2pH^2 + O(H^4) & \text{for branch}(1), \\ \frac{(p-1)(q-1)(2q-3)}{2pq(q-2)^2} + O(H^2) & \text{for branch}(2), \end{cases} \]
\[ (2.36) \]
which gives the eigenvalue as
\[ \omega = \omega_{\pm} := \begin{cases} \frac{1}{2} \left( -p \pm \sqrt{p^2 + p^2} \right) H + O(H^2) & \text{for branch}(1) \\ -pH \pm \frac{i}{q-2} \sqrt{(p-1)(q-1)(2q-3) + O(H^2)} & \text{for branch}(2) \end{cases} \]
\[ (2.37) \]
For the branch (1), the mode \( \omega_- \) is negative but the other mode \( \omega_+ \) is positive. Hence the solution is unstable. On the other hand, for the branch (2), both modes \( \omega_{\pm} \) have a negative real part for \( H > 0 \). So the solution is stable. We conclude that the branch (2) solutions with negative \( A_q \) are always stable, while the branch (1) solutions with positive
We summarize the existence conditions for de Sitter solutions in the present model and their stability in Table I.

| \(q\) | branch | \(A_q\) | \(\Lambda\) | stability |
|---|---|---|---|---|
| 1 | - | No | No | - |
| 2, 3 | (1) | \(A_q \geq 0\) | \(\Lambda \geq 0\) | unstable |
| \(\geq 4\) | (1) | \(A_q \geq 0\) | \(\Lambda \geq 0\) | unstable |
| \(\geq 4\) | (2) | \(A_q \leq A_q^{(M)} = -\frac{1}{2(q-2)^2}\) | \(\Lambda \leq \Lambda^{(M)} = -\frac{q_1}{8(q-2)\Lambda}\) | stable |

TABLE I: The range of \(A_q\) where de Sitter solutions \((\Lambda > 0, H^2 > 0)\) exist.

### III. LOVELOCK GRAVITY

The preceding sections discussed the case only with \(\alpha_2\), which is known as the next leading contribution in heterotic string theory. Here we consider the effects of further higher-order Lovelock gravity.

#### A. Basic Equations

We consider the following action:

\[
S = \frac{1}{2\kappa_D^2} \int d^D x \sqrt{-g} \sum_{n=0}^{n_{\text{max}}} \alpha_n L_n ,
\]

where \(n\)-th order Lovelock terms \(L_n\) are given by

\[
L_n := \frac{1}{2^n} \delta^{i_1 \cdots i_2n}_{j_1 \cdots j_2n} R^{i_1 j_1} R^{i_2 j_2} \cdots R^{i_{2n} j_{2n}} ,
\]

\(\alpha_n\)'s are their coupling constants with \(\alpha_1 = 1\), and \(L_0 = 1, L_1 = R\) and \(L_2 = R^2_{\text{GB}}\). We set \(\alpha_0 = -2\Lambda\), where \(\Lambda\) is a cosmological constant. Note that \(n \leq n_{\text{max}} := [(D - 1)/2]\), beyond which no dynamical contributions by Lovelock terms exist.

Assuming our spacetime is \((\text{de Sitter spacetime}) \times (\text{a static maximally symmetric space})\), we find the field equations with \(n\)-th order Lovelock gravity terms \([36]\):

\[
-2\Lambda + \sum_{n=1}^{n_{\text{max}}} \alpha_n \sum_{k=0}^{n} n \beta_k \frac{(p+1)!}{(p+1-2n+2k)!} \frac{(q-1)!}{(q-1-2k)!} H^{2(n-k)} A_k^n = 0 ,
\]

\[
-2\Lambda + \sum_{n=1}^{n_{\text{max}}} \alpha_n \sum_{k=0}^{n} n \beta_k \frac{p!}{(p-2n+2k)!} \frac{q!}{(q-2k)!} H^{2(n-k)} A_k^n = 0 .
\]

In Eqs. (3.3) and (3.4), nontrivial terms exist for \(n - [(p+1)/2] \leq k \leq [(q-1)/2]\) and \(n - [p/2] \leq k \leq [q/2]\), respectively. Hence, the power exponents of \(H^2\) and \(A_q\) satisfy \((n-k) \leq [(p+1)/2]\) and \(k \leq [(q-1)/2]\) in Eq. (3.3) and \((n-k) \leq [p/2]\) and \(k \leq [q/2]\) in Eq. (3.4). As a result, Eqs. (3.3) and (3.4) are quadratic equations for \(H^2\) if \(p \leq 4\) and those for \(A_q\) if \(q \leq 5\), respectively. Eliminating \(\Lambda\) from Eqs. (3.3) and (3.4), we find

\[
H^4 \left[ \sum_{n=2}^{n_{\text{max}}} \frac{\alpha_n}{2} \frac{n(n-1)p_2 [2D - n(p+1)] (q-1)!}{2D - n(p+1)] (q-1)!} A_{q-2}^{(n-2)} \right] + H^2 \left[ \sum_{n=1}^{n_{\text{max}}} \frac{\alpha_n}{2} \frac{n(p-1)p [D - n(p+1)] (q-1)!}{(q-2n+2)!} A_{q-1}^{(n-1)} \right] - \sum_{n=1}^{n_{\text{max}}} \frac{\alpha_n}{2} \frac{n(q-1)!}{(q-2n)!} A_q^n = 0
\]

(3.5)
if $p \leq 4$, and
\[
\begin{align*}
A_q^2 &\sum_{n=2}^{n_{\text{max}}} \frac{n(n-1)(q-1)(p-2n+5)!}{2}\frac{n^p}{(p-2n+5)!}H^{2(n-2)} \\
+ A_q &\sum_{n=1}^{n_{\text{max}}} \frac{n(q-1)(p-2n+3)!}{p^2}H^{2(n-1)} \\
&\sum_{n=1}^{n_{\text{max}}} \frac{n}{p^2(n-1)!}H^{2n} = 0 \quad (3.6)
\end{align*}
\]
if $q \leq 5$. We can easily solve these quadratic equations. For the obtained solution of $H^2$ in terms of $A_q$ ($p \leq 4$), or that of $A_q$ in terms of $H^2$ ($q \leq 5$), the cosmological constant is explicitly given by one variable as
\[
2\Lambda = \sum_{n=1}^{n_{\text{max}}} \frac{n^3}{(p-2n+2k)!}H^{2(n-k)}A_k^3. \quad (3.7)
\]
We then obtain one parameter family of analytic solutions: $H^2(A_q)$ and $\Lambda(A_q)$ for $p \leq 4$, or $A_q(H^2)$ and $\Lambda(H^2)$ for $q \leq 5$.

Note that the above ansatz of $p \leq 4$ or $q \leq 5$ is not so strong restriction. Superstring theory and M-theory predict D=10 and 11, respectively, for which dimensions we find either $p \leq 4$ or $q \leq 5$ because $p + q = D - 1 \leq 10$. Hence, for such fundamental theories, we always find one parameter family of analytic solutions.

In what follows, we discuss the first case with $p \leq 4$ because it includes the realistic dimension $p = 3$. We also consider only cubic and quartic Lovelock terms. It is the most general case for ten-dimensional superstring theory because $n_{\text{max}} = 4$ for $D = 10$. Although we should include further higher-order Lovelock terms for the theories in dimension higher than ten such as M-theory, we may ignore those higher-order terms if the Lovelock terms originate from quantum corrections.

The quadratic equation (3.3) and the cosmological constant (3.7) are explicitly given as follows:
\[
\begin{align*}
p_2 H^4 &\sum_{k=0}^{k_p} \frac{p^4}{(p-2n+2k)!}H^{2(n-k)}A_k^3 \\
&\sum_{n=1}^{n_{\text{max}}} \frac{n^3}{(p-2n+2k)!}H^{2(n-k)}A_k^3 \\
&&\sum_{n=1}^{n_{\text{max}}} \frac{n^3}{(p-2n+2k)!}H^{2(n-k)}A_k^3 = 0. \quad (3.8)
\end{align*}
\]
\[
2\Lambda = \sum_{n=1}^{n_{\text{max}}} \frac{n^3}{(p-2n+2k)!}H^{2(n-k)}A_k^3. \quad (3.9)
\]

When we include the GB term, the coefficient $\alpha_2$ must be positive in order to avoid a ghost. Hence we normalize the variables and coupling constants by $\alpha_2$ as
\[
\tilde{H} = \sqrt{\alpha_2} H, \quad \tilde{A}_q = \frac{\alpha_2}{\alpha_2} A_q, \quad \tilde{\Lambda} = \frac{\alpha_2}{\alpha_2} \Lambda, \quad (3.10)
\]
In what follows, we drop a tilde for brevity.

\section*{B. Perturbation equations}

In order to analyze stability, we perturb the basic equations. Here we consider general case with $n \leq 4$. We find two independent perturbation equations:
\[
P\dot{\xi} + Q\dot{\eta} + R\eta = 0, \quad (3.11)
\]

\[
S\dot{\xi} + T\dot{\eta} + U\dot{\xi} + V\dot{\eta} + W\eta = 0, \quad (3.12)
\]
where the coefficients are defined by
\[
P := p_1HX, \\
Q := pqHY, \\
R := -pqH^2Y, \\
S := pY, \\
T := \frac{pH^2}{A_q}Y, \\
U := (p + 1)qHY, \\
V := \frac{p^2H^3}{A_q}Y, \\
W := -(q - 1)2A_qZ, \quad (3.13)
\]
with
\[
X := 1 + 2\left( (p - 2)qH^2 + q_1 A_q \right) + 3\alpha_3 \left( (p - 2)qH^4 + 2(p - 2)q_1 H^2 A_q + q_3 A_q^2 \right) + 4\alpha_4 \left( (p - 2)qH^6 + 3(p - 2)q_1 H^4 A_q + 3(p - 2)q_3 H^2 A_q^2 + q_5 A_q^3 \right),
\]
\[
Y := 1 + 2\left( (p - 1)qH^2 + (q - 1)q_2 A_q \right) + 3\alpha_3 \left( (p - 1)qH^4 + 2(p - 1)q_2 H^2 A_q + (q - 1)q_4 A_q^2 \right) + 4\alpha_4 \left( (p - 1)qH^6 + 3(p - 1)q_2 H^4 A_q + 3(p - 1)q_4 H^2 A_q^2 + (q - 1)q_6 A_q^3 \right),
\]
\[
Z := 1 + 2\left( (p + 1)qH^2 + (q - 3)q_4 A_q \right) + 3\alpha_3 \left( (p + 1)qH^4 + 2(p + 1)q_4 H^2 A_q + (q - 3)q_8 A_q^2 \right) + 4\alpha_4 \left( (p + 1)qH^6 + 3(p + 1)q_4 H^4 A_q + 3(p + 1)q_8 H^2 A_q^2 + (q - 3)q_8 A_q^3 \right),
\]
(3.14)

Eliminating \( \xi \), we find a single equation:
\[
\ddot{\eta} + p H \dot{\eta} + C \eta = 0,
\]
where
\[
C := \frac{P W - RU}{PT - SQ} = \frac{A_q \left[ (p + 1)qH^2 Y^2 - (p - 1)(q - 1)q_2 A_q X Z \right]}{p Y \left[ (p - 1)H^2 X - q_1 A_q Y \right]}.
\]

Setting \( \eta = \eta_0 e^{\omega t} \), we obtain the equation for the eigenvalue \( \omega \) as
\[
\omega^2 + p H \omega + C = 0. \tag{3.17}
\]
If \( \omega > 0 \) (or \( \Re \omega > 0 \)), then the perturbation is unstable. Hence we find the stability condition for the expanding universe \( (H > 0) \) as
(1) both eigenvalues are negative, i.e.,
\[
p^2 H^2 - 4C \geq 0, \quad C > 0 \tag{3.18}
\]
or
(2) the eigenvalues are complex conjugate numbers with negative real part (for \( p H > 0 \)), i.e.,
\[
p^2 H^2 - 4C < 0. \tag{3.19}
\]
Altogether we find the stability condition is just \( C > 0 \).

The difference from the case only with the GB term is the definition of \( X, Y \) and \( Z \).

C. Minkowski spacetime

Although we are interested in a self-accelerating de Sitter spacetime, it is worth to study Minkowski spacetime, which is given by \( H = 0 \). Eq. (3.15) or (3.18) gives
\[
-(q - 1)A_q^{(M)} \left[ 1 + 2(q - 2)A_q^{(M)} + 3\alpha_3 (q - 2)A_q^{(M)} \right]^2 + 4\alpha_4 (q - 2)A_q^{(M)^3} = 0.
\]
(3.20)
There are two branches: One is a trivial solution \( A_q^{(M)} = 0 \) and the other is given by the roots of the cubic (quadratic, or linear) equation
\[
1 + 2(q - 2)A_q^{(M)} + 3\alpha_3 (q - 2)A_q^{(M)} = 0.
\]
(3.21)
A trivial solution \( A_q^{(M)} = 0 \) corresponds to \( \sigma_q = 0 \), which is a torus compactification. This Minkowski spacetime with \( A_q^{(M)} = 0 \) is always a solution.

So, in what follows, we mainly discuss the case of \( A_q^{(M)} \neq 0 \). We can classify the solutions as follows:

(a) \( q = 2, 3 \): No solution.

(b) \( q = 4, 5 \): There exists one negative solution:
\[
A_q^{(M)} = -\frac{1}{2(q - 2)3}.
\]
(3.22)

(c) \( q = 6, 7 \): Here \( \alpha_4 \) term is absent. If \( \alpha_3 \neq 0 \), there exist two solutions:
\[
A_q^{(M)} = \frac{1}{3\alpha_3 (q - 4)5} \left[ -1 \pm \sqrt{1 - \frac{3\alpha_3 (q - 4)5}{(q - 2)3} \right]
\]
(3.23)
if
\[
\alpha_3 \leq \frac{(q - 2)3}{3(q - 4)5}.
\]
(3.24)
For \( \alpha_3 > 0 \), both solutions are negative, while for \( \alpha_3 < 0 \), one with plus sign is negative and the other with minus sign is positive. No solution exists for
\[
\alpha_3 > \frac{(q - 2)3}{3(q - 4)5}.
\]
(3.25)
When \( \alpha_3 = 0 \), there exists one negative solution.

(d) \( q \geq 8 \): Three real solutions exist if
\[
\alpha_{4,cr}^{(-)} \leq \alpha_4 \leq \alpha_{4,cr}^{(+)},
\]
where
\[
\alpha_{4,cr}^{(\pm)} = \frac{4((q-2)A_3)^2}{27(q-4)^7} \left( -\left( 1 - \frac{27\alpha_3(q-4)_5}{8(q-2)_3} \right) \right) ^{3/2},
\]
with
\[
\alpha_3 \leq \frac{4(q-2)A_3}{9(q-4)_5}.
\]

For \( q = 8 \), we show the existence range by the light-red shaded region in Fig. 4.

If the condition (3.26) is not satisfied, there exists only one real solution (shown by the white region in Fig. 4). It is negative for \( \alpha_4 > 0 \) while positive for \( \alpha_4 < 0 \).

\[
\text{FIG. 4: Three solutions exist in the light-red shaded region for } q = 8, \text{ while there exists only one solution in the white region. On the red solid and dashed lines, two solutions and no solution exist, respectively.}
\]

When \( \alpha_4 = 0 \), we find the same solutions as in the case (c). For \( q = 8 \), it is also shown by the red solid (two solutions) and dashed lines (no solution) in Fig. 4.

D. Stability of near-Minkowski spacetime

To analyze stability, we first consider spacetimes near Minkowski spacetime. It may be important because the realistic inflation predicts that the Hubble expansion rate \( H \) must be much smaller than the Planck scale (a natural scale of vacuum expectation value of fundamental fields, which acts as a cosmological constant).

Near a trivial Minkowski spacetime with \( A_q^{(M)} = 0 \), we have
\[
A_q = \frac{p}{q-1}H^2 + O(H^4) \quad \text{(3.29)}
\]
\[
\Lambda = \frac{p(p + q - 1)}{2}H^2 + O(H^4). \quad \text{(3.30)}
\]

Using this approximate solution, we find the equation for \( \omega \) as
\[
\omega^2 + pH\omega - 2pH^2 = 0,
\]
which has one positive and one negative roots for \( H \neq 0 \). Hence the solution is always unstable.

Next we analyze another branch with \( A_q^{(M)} \neq 0 \). Expanding \( A_q \) as
\[
A_q = A_q^{(M)} + A_q^{(2)}H^2 + O(H^4), \quad \text{(3.32)}
\]
where \( A_q^{(M)} \) is given by the solution of Eq. (3.21), we find the solutions near Minkowski by with

\[
A_q^{(2)} = -\frac{p}{(q-1)_3} \left[ (pq - p - 3q + 5) + 3\alpha_3(pq - p - 3q + 9)(q-2)_3A_q^{(M)} + 6\alpha_4(pq - p - 3q + 13)(q-2)_4 \left( A_q^{(M)} \right)^2 \right] \]
\[
(q-1)_3 \left[ 1 + 3\alpha_3(q-4)_5A_q^{(M)} + 6\alpha_4(q-4)_7 \left( A_q^{(M)} \right)^2 \right].
\]

The cosmological constant is given by
\[
\Lambda = \Lambda^{(M)} + \frac{p_1}{2}X^{(M)}H^2 + O(H^4), \quad \text{(3.33)}
\]
where
\[
\Lambda^{(M)} := \frac{q_1}{2}A_q \left[ 1 + (q-2)_3A_q^{(M)} + \alpha_3(q-2)_5(A_q^{(M)})^2 \right]
\]
\[
X^{(M)} := X(H = 0, A_q = A_q^{(M)}).
\]
Assuming $H^2 \ll 1$, the coefficients $C$ in (3.17) is rewritten as

$$C = \frac{(p-1)(q-1)2A_q^{(M)}X^{(M)}Z^{(M)}}{pq(Y^{(M)})^2} + O(H^2), (3.34)$$

where

$$Y^{(M)} = Y(H = 0, A_q = A_q^{(M)})$$
$$Z^{(M)} = Z(H = 0, A_q = A_q^{(M)}). \quad (3.35)$$

We find the eigenvalues

$$\omega_\pm = \frac{1}{2} \left( -pH \pm \sqrt{-4C} \right) + O(H^2).$$

If $C \geq 0$, the expanding de Sitter spacetime is stable. For $q = 4, 5$, the stability condition amounts to

$$\alpha_3 \leq \frac{8(2q-3)}{3q_1}. \quad (3.36)$$

Note that $A_q^{(M)}$ is always negative just as the case only with the GB term.

We can show that $\Lambda^{(M)} < 0$ and $A_q^{(M)} < 0$ for the plus branch of the solution (3.23), while in the minus branch,

$$\Lambda^{(M)} < 0 \quad \text{for} \quad \frac{(q-2)_4}{4(q-4)_5} < \alpha_3 < \frac{(q-2)_3}{3(q-4)_5}$$
$$\Lambda^{(M)} > 0 \quad \text{for} \quad \alpha_3 < \frac{(q-2)_3}{4(q-4)_5}. \quad (3.37)$$

Hence, unlike the case only with the GB term, we obtain stable de Sitter solutions near Minkowski spacetime not only for a negative cosmological constant but also for a positive one.

We also show the parameter region of stable Minkowski solutions for $D = 12$ ($q = 8$) in Fig. 6. The numbers denote how many solutions are stable. The blue and green regions give a negative and positive cosmological constant, respectively. The meshed and un-meshed regions correspond to $A_q^{(M)} > 0$ and $A_q^{(M)} < 0$, respectively. Although the figure is complicated, the result is similar to the case of $D = 10$.

In the next section, we study de Sitter solutions and their stabilities for the case with cubic and quartic Lovelock gravity terms.
FIG. 6: Stable (light-blue, meshed light-blue, light-green and meshed light-green) regions of Minkowski spacetime for \( D = 12 \) (\( q = 8 \)). The numbers denote how many solutions are stable. The blue and green regions give a negative and positive cosmological constant, respectively. The meshed and un-meshed regions correspond to \( A_q^{(M)} > 0 \) and \( A_q^{(M)} < 0 \), respectively. There is no stable solution in the white region.

**IV. DE SITTER SPACETIMES WITH HIGHER-ORDER LOVELOCK TERMS AND THEIR STABILITY**

As we discussed in Secs. [IIA][12][IIB][13] and [IIC] in the theory with GB term and a cosmological constant, we find two branches: The branch (1) gives (de Sitter spacetime) \( \times \) (an internal space with a positive curvature), which is unstable, and the branch (2) is (de Sitter spacetime) \( \times \) (an internal space with a negative curvature), which is stable. In this section, including higher-order Lovelock terms, we discuss the effect of higher-order terms. Following the previous discussion about near-Minkowski spacetime, we consider three cases: (1) \( D = 8 \) (\( p = 3, q = 4 \)), (2) \( D = 10 \) (\( p = 3, q = 6 \)), and (3) \( D = 12 \) (\( p = 3, q = 8 \)). Note that \( D = 10 \) is predicted by superstring theory.

Solving the quadratic equation (3.8), we find the Hubble expansion parameter \( H \) as

\[
H^2 = H_\pm^2 := -\frac{3}{24} \left[ 1 + 2(q - 4)(q - 1)_3 A_q + 3q_3(q - 8)(q - 1)_3 A_q^2 + 4q_4(q - 12)(q - 1)_5 A_q^3 \right] \pm \sqrt{D} \tag{4.1}
\]

with

\[
D := 48(q - 1)_4 [1 + 2(q - 2)_3 A_q + 3q_3(q - 1)_3 A_q^2] [1 + 3q_3(q - 1)_2 A_q + 6q_4(q - 1)_4 A_q^2] + 9 [1 + 2q_4(q - 4)(q - 1)_3 + 3q_4 A_q^2(q - 8)(q - 1)_3 + 4q_4 A_q^3(q - 12)(q - 1)_5]^2. \tag{4.2}
\]

\( H_\pm^2 \) as well as \( D \) must be positive to find a real Hubble parameter. These conditions restrict the existence of the de Sitter solution. The cosmological constant is given in terms of \( A_q \) by the solution (4.1) as

\[
\Lambda = \Lambda_\pm := 3H_\pm^2 \left[ 1 + 2q_1 A_q + 3q_3 A_q^2 + 4q_4 A_q^3 \right] + \frac{q_1}{2} A_q \left[ 1 + (q - 2)_3 A_q + \alpha_3(q - 2)_5 A_q^2 \right]. \tag{4.3}
\]

The coefficient \( C \) in Eq. (3.10) for perturbation equations is given by

\[
C = \frac{2A_q^2 [6qH^2 Y^2 - (q - 1)_2 A_q X Z]}{3Y [2H^2 X - qA_q Y]} \tag{4.4}
\]

with

\[
X := 1 + 2q_1 A_q + 3q_3 A_q^2 + 4q_4 A_q^3, \tag{4.5}
\]

\[
Y := 1 + 2 \left( 2H^2 + (q - 1)_2 A_q \right) + 3q_3(q - 1)_2 \left( 4H^2 + (q - 3)_4 A_q \right) A_q^3 + 4q_4(q - 1)_4 \left( 6H^2 + (q - 5)_6 A_q \right) A_q^5. \tag{4.6}
\]
13

\[ Z := 1 + 2 \left( 12H^2 + (q - 3)A_q \right) \]
\[ + \ 3\alpha_3 \left( 24H^4 + 24(q - 3)A_q + (q - 3)A_q^2 \right) \]
\[ + \ 144\alpha_4(q - 3) \left( 2H^2 + (q - 5)A_q \right) H^2 A_q. \quad (4.7) \]

The stability condition for an expanding universe is \( C \geq 0 \), which is the same as the case only with the GB term. The difference is the definition of \( X, Y, \) and \( Z. \)

In the followings, we show numerical results. We analyze two limited cases: \( A, \alpha_3 = 0, \) and \( B, \alpha_4 = 0, \) and discuss more general cases in \( C. \)

\begin{center}
A. The effect of the quartic Lovelock term with \( \alpha_4 (\alpha_3 = 0) \)
\end{center}

In this subsection, we discuss the effect of the quartic Lovelock term with the coupling constant \( \alpha_4. \) For \( D = 8, \) no quartic Lovelock term appears. Then we first discuss the case of \( D = 10. \) In Fig. 7, we summarize our result on the \( \alpha_4-A_6 \) plane. The reason why we choose the value of \( A_6 \) to describe the solutions is because just the Hubble parameters \( H^2_\pm \) and the cosmological constant \( \Lambda_\pm \) are uniquely determined by giving the value of \( A_6. \) The de Sitter solution exists in the colored regions: The meshed blue and meshed dotted green regions give the stable dS solutions with a negative and positive cosmological constants, respectively. The dS solution in the light-red shaded region is unstable.

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{figure7.png}
\caption{The de Sitter solution exists in the colored region on the \( \alpha_4-A_6 \) plane for \( D = 10 (\alpha_3 = 0). \) The meshed blue and meshed dotted green regions give the stable dS solutions with a negative and positive cosmological constants, respectively. The dS solution in the light-red shaded region is unstable. The red lines at \( A_6 = 0 \) and at \( A_6 = -\frac{1}{24} \) denote Minkowski spacetimes. The left small figure is the enlarged one of the part of the right figure.}
\end{figure}

From this figure, we can classify the solutions into the following four cases (A)-(D):

(A) \( \alpha_4 > 0 \)
There exists stable de Sitter solutions with a negative cosmological constant for a finite negative range of \( A_6. \) The solutions with positive \( A_6 \) or with large negative \( A_6 \) are unstable. There exists one stable Minkowski spacetime for \( A_6 = -1/24. \) In Fig. 8, we show one example for \( \alpha_4 = 1. \)

For the branch (2), \( A_6 \) is always negative as the case only with GB term, but a cosmological constant becomes positive for the large negative value of \( A_6. \) On the other hand, for the branch (1), we find \( A_6 \geq 0 \) and \( \Lambda \geq 0, \) which are the same as the case only with GB term.

We show the eigenvalues in Fig. 9 to see the stability of the solutions. The green curves give two stable modes, i.e. two negative eigenvalues or negative real part of two complex conjugate eigenvalues. These solutions are stable. On the other hand, the red and blue curves denote the unstable and stable modes, respectively. Hence such solutions are unstable. This result means that the solutions in the branch (1) are unstable and those in the branch (2) are stable for near-Minkowski spacetime. It
FIG. 8: The de Sitter solutions ($H^2$; Solid curves) with a static extra dimensions ($A_6$; Dashed curves) in terms of a cosmological constant $\Lambda$ for two branches (branch (1) and branch (2)) in the case of $\alpha_4 = 1$. The stable solutions are denoted by the green curves, while the unstable ones are by the red ones.

FIG. 9: The eigenvalues $\omega$ in terms of $A_6$ for $\alpha_4 = 1$. For a given value of $A_6$, the green solid and dashed curves give two negative and negative real part of two complex conjugate eigenvalues, respectively, while the red and blue curves are positive and negative eigenvalues, respectively. The solutions given by the green curves in the branch (2) are stable, otherwise unstable.

shows the same behaviour as those in the theory only with GB term. However, the solutions in the branch (2) turn to be unstable when the curvature scale of the extra dimensions ($|A_6|$) increases beyond a critical value (compare with Fig. 3).

For the other positive values of $\alpha_4$, we find similar results, i.e., there exists one stable branch of de Sitter solutions, for which $A_6$ and $\Lambda$ are always negative.

(B) $-196/45 < \alpha_4 < 0$

There exists de Sitter solution with a negative cosmological constant for a finite negative region of $A_6$.

For the positive value of $A_6$, there are two de Sitter solutions: one is unstable and the other is stable, for which a cosmological constant is positive. Only one stable Minkowski spacetime is possible for $A_6 = -1/24$.

(C) $-36/5 < \alpha_4 < -196/45$

This region is rather complicated. Changing the value of $A_6$, the stability and the sign of the cosmological constant changes frequently. We show one complex example with $\alpha_4 = -6$ in Fig. 10. There are three branches: (1) which includes a trivial Minkowski spacetime with $A_6 = 0$, (2) which include a stable Minkowski spacetime with $A_6 = -1/24$, and (3) which newly appears and does not involve a Minkowski spacetime. The eigenvalues are shown in Fig. 11, from which we find the stability of the solutions.

There exists one stable de Sitter solution with a negative cosmological constant. The cosmological constant should be in a finite range of negative values. In addition, we find three stable de Sitter solutions, which belong to each branch, for large positive value of the cosmological constant. These solutions are interesting because some solutions provide us the possibility of rather small Hubble parameter in spite of large value of a cosmological constant, which may explain the discrepancy between a preferred scale of inflation (GUT scale) and the Planck scale. For a given
FIG. 10: The de Sitter solutions ($H^2$) with a constant internal space ($A_6$) in terms of a cosmological constant $\Lambda$ for $\alpha_4 = -6$. There are three branches (the branch (1), branch (2) and branch (3), which newly appears and does not involve a Minkowski spacetime). The stable solutions are denoted by the green curves, while the unstable ones are by the red ones.

FIG. 11: The eigenvalues in three branches (1), (2) and (3) in terms of a cosmological constant $\Lambda$ for $\alpha_4 = -6$. The green solid and dotted curves denote two negative eigenvalues and a positive real part of two complex conjugates, respectively, which means those are stable solutions. The red and blue curves denote positive and negative eigenvalues, respectively. Those solutions are unstable.

The behaviour of the solutions is almost the same as the case [3], but de Sitter solution near Minkowski spacetime becomes unstable.

We also show the case of $D = 12$ in Fig. 12. The detail structure is very complicated, but the global feature does not change so much. The features are as follows: For $\alpha_4 > 0$, there exists a stable de Sitter solution with a negative cosmological constant for any negative $A_8$. If $\alpha_4 < 0$, we also find stable de Sitter solutions with negative values of $A_8$, but the cosmological constant must be positive.
FIG. 12: The de Sitter solution exists in the colored region on the $\alpha_4-A_q$ plane for $D = 12$ ($\alpha_3 = 0$). The meshed blue and meshed dotted green regions give the stable dS solutions with a negative and positive cosmological constants, respectively. The dS solution in the light-red shaded region is unstable. The red curves denote Minkowski spacetime. The left small figure is the enlarged one of the part of the right figure.

B. The effect of the cubic Lovelock term with $\alpha_3$ ($\alpha_4 = 0$)

For the case with the cubic Lovelock term ($\alpha_3 \neq 0$) but without the quartic term ($\alpha_4 = 0$), we summarize our result on the $\alpha_4-A_q$ plane for $D = 8, 10$ and 12 in Figs. 13(a)–(c), respectively.

In the case of $D = 8$, for $A_4 < 0$, there exist stable de Sitter solutions (including Minkowski spacetime) with $\Lambda < 0$ if $\alpha_3 < \frac{10}{9}$. On the other hand, for $A_4 > 0$, although there are a few stable de Sitter solutions with $\Lambda > 0$, most de Sitter solutions are unstable. For the cases of $D = 10$ and $D = 12$, apart from the small fine structures, the global features of Figs. 13(b) and (c) are very similar. The de Sitter solutions with $A_q < 0$ are mostly stable, and $\Lambda < 0$ for $\alpha_3 < 0$, while $\Lambda > 0$ for $\alpha_3 > 0$. On the other hand, the solutions with $A_q > 0$ are unstable except for a few tuned solutions. Minkowski spacetime with a negative $A_q$ are mostly stable except for a small range of parameters (a part of the red curve next to the unstable light-red region), which is found in the enlarged figures of Figs. 13(b) and (c).

From these figures, we can draw the following conclusions:

1. There exist stable de Sitter solutions with a negative $A_q$ and a negative cosmological constant for $\alpha_3 < 0$.

2. There exist stable de Sitter solutions with a negative $A_q$ and a positive cosmological constant for $\alpha_3 > 0$ if $D \geq 10$.

3. There exist a few stable de Sitter solutions with a positive $A_q$. Most solutions are unstable.

From Figs. 13, we can find the sign of $\Lambda$, but do not know the precise values. Since we are interested in the discrepancy between $H$ and $\Lambda$ in an inflationary scenario, we also show typical solutions for $D = 10$ in Fig. 14 and 15 for some given coupling constant $\alpha_3$.

For the case with $\alpha_3 = 2$ in Fig. 14, the branches (2) and (2)' have stable de Sitter spacetimes with negative $A_q$. The cosmological constants can be negative, but they are continuously extended to positive values up to $+\infty$. Hence although de Sitter solution is possible for a negative cosmological constant, we also find that with a positive cosmological constant, the branch (2) may give us small Hubble parameter for a Planck scale cosmological constant, which is preferred inflation.

On the other hand, for the case with $\alpha_3 = -2$ in Fig. 15 one branch (2) gives a stable de Sitter solution with negative $A_q$ and a negative cosmological constant, which is unbounded from below. The Hubble expansion scale can be small compared with the negative cosmological constant. There also exists one new branch (3), which has a stable de Sitter solution with positive $A_q$ and a positive cosmological constant, which is unbounded from above. The possibility of small Hubble parameter for inflation may not be found in the branch (3), because $H$ diverges as $\Lambda \to \infty$.  

Hence, although de Sitter solution is possible for a negative cosmological constant, we also find that with a positive cosmological constant, the branch (2) may give us small Hubble parameter for a Planck scale cosmological constant, which is preferred inflation.
To summarize, we have stable de Sitter solutions with a negative cosmological constant when $\alpha_3$ is negative.

C. The effect of generic Lovelock terms ($\alpha_3, \alpha_4 \neq 0$)

To confirm the above results on the effects of the cubic and quartic Lovelock gravity terms, we perform calculations for the generic case with $D = 10$. We show the results in Fig. 16 for given $\alpha_4$ and in Fig. 17 for given $\alpha_3$.

In Fig. 16 setting $\alpha_4 = -10, -1, 0, 1, 10$, we present the existence region of de Sitter solutions and their stabilities on the $\alpha_3$-$A_6$ plane. The meshed blue and meshed dotted green regions give the stable dS solutions with a negative and positive cosmological constants, respectively. The dS solution in the light-red shaded region is unstable. Note that the red curves denote Minkowski spacetime. The stability structure is very complicated, but we also find the following overall features. We find a stable de Sitter solution with a negative cosmological constant (meshed blue region) when $\alpha_3 < 0$. In this case, $A_6$ is mostly negative, but the restricted region appears for $\alpha_4 < 0$. On the other hand, there exists a stable de Sitter solution with a positive cosmological constant (meshed green region) when $\alpha_3 > 0$. $A_6$ is always negative, but the existence region is restricted for $\alpha_4 > 0$. The solutions with $A_6 > 0$ are mostly unstable.

In Fig. 17 setting $\alpha_3 = -10, -1, 0, 1, 10$, we present the similar figures on the $\alpha_4$-$A_6$ plane. The stability structure is again very complicated, but we also find the following global features. We find a stable de Sitter solution with a negative cosmological constant (meshed blue region) when $\alpha_3 < 0$. In this case, $A_6$ is mostly negative, but the restricted region appears for $\alpha_4 < 0$. On the other hand, there exists a stable de Sitter solution with a positive
FIG. 14: The solution for $\alpha_3 = 2$. There are two branches of solutions (1) and (2), as shown in the figure. We also find the branch (2)' similar to the branch (2), but it includes an unstable Minkowski spacetime. The solutions denoted by the green solid and dotted curves are stable, while the red ones are unstable.

FIG. 15: The solution for $\alpha_3 = -2$. There are three branches of solutions (1), (2) and (3), as shown in the figures. The branch (3) has no Minkowski spacetime. The solutions denoted by the green solid and dotted curves are stable, while the red ones are unstable.

cosmological constant (meshed green region) when $\alpha_3 > 0$. $A_6$ is mostly negative, but the restricted region is found for $\alpha_3 > 0$. The solutions with $A_6 > 0$ are mostly unstable.

From those figures, we can conclude that a stable de Sitter solution with a negative cosmological constant is obtained if $\alpha_3 < 0$, although the existence region of negative $A_6$ is constrained for $\alpha_3 > 0$. Conversely, a stable de Sitter solution with a positive cosmological constant is obtained if $\alpha_3 > 0$, although the existence region of negative $A_6$ is constrained for $\alpha_3 > 0$. The solutions with $A_6 > 0$ are mostly unstable.

Next, setting $\alpha_3 = \pm 1$ and $\alpha_4 = \pm 1$, we show the explicit solutions in terms of $\Lambda$ in Fig. 18. The green and red curves correspond to the stable and unstable solutions, respectively. From these figures, we can confirm that a stable de Sitter solution with a negative cosmological constant (branch (2) solution) exists for $\alpha_3 = -1$, while a stable de Sitter solution with a positive cosmological constant (branch (2) and (2)' appears for $\alpha_3 = 1$. For the branch (1), a stable de Sitter spacetime appears for larger values of positive $\Lambda$.

One interesting observation is that there exist stable de Sitter solutions with large (negative or positive) cosmological constants for any coupling constants (See the branch (2) and (1) in Fig. 18(a), the branch (2) and (3) in Fig. 18(b), the branch (2) and (2)' in Figs. 18(c), and (d)). This may explain the discrepancy between an inflation scale and the Planck scale.

V. CONCLUDING REMARKS

We have studied gravitational theories with a cosmological constant and the Gauss-Bonnet curvature squared term. We find that there are two branches of the de Sitter solutions: Both the curvature of the internal space
FIG. 16: For given $\alpha_4$ [(a) $\alpha_4 = -10$, (b) $\alpha_4 = -1$, (c) $\alpha_4 = 0$, (d) $\alpha_4 = 1$, (e) $\alpha_4 = 10$], the existence of de Sitter solutions and their stabilities are shown on the $\alpha_3-A_6$ plane. The meshed blue and meshed dotted green regions give the stable dS solutions with a negative and positive cosmological constants, respectively. The dS solution in the light-red shaded region is unstable. The red curves denote Minkowski spacetime.

and the cosmological constant are (1) positive and (2) negative. By the stability analysis, we have shown that the de Sitter solution of the branch (1) is unstable, while that in the branch (2) is stable. It is remarkable that we have de Sitter solutions even for a negative cosmological constant, which are the only stable ones. We again note that we have not studied the stability of other possible moduli in extra dimensions, but the above stability is an important property for useful solutions.

We have also extended our analysis to the gravitational theories with further higher-order Lovelock curvature terms. Although the existence and the stability of the de Sitter solutions are very complicated and highly depend on the coupling constants $\alpha_3$ and $\alpha_4$, there exist stable de Sitter solutions similar to the branch (2) for $\alpha_3 < 0$. We also find stable de Sitter solutions with positive cosmological constants if $\alpha_3 > 0$. For most stable de Sitter solutions, the Hubble scale can be much smaller than the scale of a cosmological constant, which may explain a discrepancy between an inflation energy scale and the Planck scale.

Although the existence of a stable de Sitter spacetime with a negative cosmological constant is interesting, it is important to find a realistic cosmological model for the early universe, in which de Sitter exponential expansion must end at some stage. It means that de Sitter solution should be a marginally unstable state instead of an absolute stable state. After more than 60 e-foldings, inflation must end and the universe must be reheated, finding a big bang initial state. Hence we have to find a graceful exist in the present model. Only after such a mechanism is found, we can discuss density perturbations and observational consequences.

There is another point to be discussed. We have shown that there are two (or more) branches of the de Sitter solutions. One branch (the branch (1)) is connected to the solutions of general relativity (GR) in the limit of $\alpha_2 \to 0$. We call it GR-branch. The other branches (the branch (2), (2)$'$ and (3)) are called non-GR branches, because there is no GR limit for any values of the coupling constants [37]. Since the present universe is well described by GR, it may be plausible that the realistic cosmological solutions belong to the GR branch. This may mean either that we should find an interesting solution in the branch (1) [for example, there exists a stable de Sitter spacetime with $\Lambda < 0$ and $A_5 < 0$ in the branch (1) for $\alpha_3 = 0, \alpha_4 = -6$ in Fig. [10], or that we should construct a realistic cosmological model including a low-energy scale universe in the other branches. These are under investigation.

The present model may be too simple from the viewpoint of a unified theory of fundamental interactions. It may be desirable to analyze more realistic models based on supergravity or superstring theory including a dilaton
FIG. 17: For given $\alpha_3$ [(a) $\alpha_3 = -10$, (b) $\alpha_3 = -1$, (c) $\alpha_3 = 0$, (d) $\alpha_3 = 1$, (e) $\alpha_3 = 10$], the existence of de Sitter solutions and their stabilities are shown on the $\alpha_4$-$A_6$ plane. The meshed blue and meshed dotted green regions give the stable dS solutions with a negative and positive cosmological constants, respectively. The dS solution in the light-red shaded region is unstable. The red curves denote Minkowski spacetime.

FIG. 18: The de Sitter solutions for (a) $\alpha_3 = -1, \alpha_4 = -1$, (b) $\alpha_3 = -1, \alpha_4 = 1$, (c) $\alpha_3 = 1, \alpha_4 = -1$, and (d) $\alpha_3 = 1, \alpha_4 = 1$. The stable solutions are shown by the green curves, while the unstable ones are by the red curves.
