Quality of life; Complete dentures

Abstract  Objective: The purpose of this study was to determine whether there is a correlation between the clinical quality of conventional complete dentures and patient quality of life.

Materials and methods: This study included a random sample of 32 completely edentulous patients (15 males and 17 females) who were treated with conventional complete dentures. Using a validated questionnaire, three investigators evaluated the dentures independently on the basis of seven clinical parameters: esthetics (lip support and lower lip line), retention and stability of the maxillary and the mandibular dentures, and occlusion. Patients completed the validated Oral Health Impact Profile-20 (OHIP-20) questionnaire. Correlations were determined by using the point-biserial correlation coefficient.

Results: Clinicians rated the overall clinical quality of the dentures satisfactory in 80.3% of patients. The mean (± standard deviation) total OHIP-20 score was 56.3 ± 15.9 out of a possible 120 maximum. A statistically significant negative correlation was found between the stability of the maxillary and mandibular dentures and the total OHIP-20 score (p = 0.009 and 0.0023, respectively). A negative correlation between the total OHIP-20 score and the retention of the mandibular denture approached significance (p = 0.092). Esthetics, retention of the maxillary denture, and occlusion were not correlated with patient quality of life (p > 0.169).

1. Introduction

The number of geriatric patients throughout the world is expected to increase in the coming decades (Organization, 2003). A substantial number of older patients will likely experience some form of tooth loss, despite efforts to improve preventative dental care programs (Adam, 2006). The World Health Organization considers edentulism to be a form of physical impairment (Organization, 2001) because edentulous patients are impaired, to some degree, in their ability to perform essential life tasks, such as eating and speaking (Brennan et al., 2010).

There have been many studies examining the effect of complete dentures on the quality of life (QoL) of edentulous patients. Allen and McMillan reported an improved health-related QoL among patients who received conventional complete dentures (Allen and McMillan, 2003). Similarly, in a sample of 34 patients, treatment with a conventional complete denture began to improve the oral health-related quality of life (OHRQoL) within a month of insertion and continued to improve the OHRQoL 6 and 12 months after treatment (John et al., 2004). Wearers of complete dentures reported high levels of satisfaction with their daily lives and with their complete dentures (Yoshida et al., 2001). The improvement in the OHRQoL reported by patients did not appear to depend on the technique used to fabricate the conventional complete denture (Ellis et al., 2007).

To the best of our knowledge, no published study to date has investigated how the technical quality of the complete denture, as assessed by the clinician, might affect the patient QoL. Therefore, the current study was performed to determine whether there is a correlation between the quality of the conventional complete denture, defined by specific esthetics and functional criteria, and patient QoL.

The null hypothesis of this study was that the technical quality of the complete denture, as evaluated by the clinician, has no effect on the QoL of the wearer.

2. Materials and methods

2.1. Patient enrollment and examination

The study was approved by the Human Ethics Board of the College of Dentistry, King Saud University (protocol reference number: NF2400). Power size calculation revealed a sample size of $N = 22$ for a power of more than 80% to detect a correlation at a significance level of $\alpha = 0.05$ ($p < 0.05$). Patients ($N = 32$) who were completely edentulous in both jaws and aged 45 years or older were randomly selected from a pool of 92 patients who had been rehabilitated by conventional complete dentures from September 2009 to January 2013. All of the dentures were fabricated by dental students. To achieve external validity, each set of dentures was fabricated by a different clinician.

To be included in the study, patients were required to be: (1) currently wearing the dentures and (2) able to communicate clearly with the clinician. Patients were excluded if they had physical and/or psychological disorders that precluded clinical examination and the completion of questionnaires. The study protocol was discussed in detail with the patients, and an informed, witnessed, and signed consent was obtained.

The clinical examination was performed by three independent clinicians. A validated clinical examination form was developed to assess the existing dentures objectively, on the basis of a detailed examination procedure. The clinical examination form included seven criteria: (1) esthetics (lip support and lower lip line) (Brunton and McCord, 1993), (2) retention of the maxillary and mandibular dentures, (3) stability of the maxillary and mandibular dentures, and (4) balanced occlusion (Watt and MacGregor, 1976; Heartwell and Rahn, 1986; Barrett, 1978; Bernier et al., 1984). All of the clinical parameters have been described precisely and were evaluated on a dichotomous scale (satisfactory = 1 and unsatisfactory = 0). The minimum score possible for an individual subject was zero and the maximum score possible was seven. The coefficient of internal consistency (Cronbach alpha) of this form was 0.69, indicating acceptable reliability.

Following the completion of the clinical examination, patients were asked to complete a modified short version of the Oral Health Impact Profile for assessing health-related quality of life in edentulous adults (OHIP-20) (Allen and Locker, 2002). This questionnaire contains 20 items, which were designed specifically for edentulous patients. The questions cover seven domains: functional limitation, physical pain, psychological discomfort, physical disability, psychological disability, social disability, and handicap. Responses are scored by a Likert scale, ranging from 1 (“never”) to 6 (“all of the time”), with a minimum total score of 20 and a maximum total score of 120. A higher score indicates compromised QoL.

2.2. Statistical analysis

Data were analyzed with the Statistical Package for the Social Sciences software (SPSS version 16.0, Chicago, IL, USA). The $\kappa$ chance-corrected index of agreement was used to assess the degree of intra- and inter-examiner agreement. With the exception of mean scores, all variables (demographic characteristics of participants and the denture quality evaluation scores) were presented as frequencies and percentages. To determine whether there was an association between the denture quality parameters and the OHIP-20 total score, the point-biserial correlation coefficient was used (statistically significant at $p < 0.05$).

3. Results

A total of 32 patients (15 males and 17 females) met the inclusion criteria and completed the study successfully (Table 1). The $\kappa$ chance-corrected index of agreement indicated near perfect agreement between the three clinicians and perfect agreement for intraexaminer reliability (Table 2).
Quality of conventional complete dentures and patients’ quality of life

4. Discussion

To the best of our knowledge, this is the first study to examine how the clinically evaluated quality of a conventional complete denture might affect the patient QoL, as measured by the OHIP-20. On the basis of our results, the null hypothesis (i.e., that there is no correlation between the technical quality of complete dentures and the patients’ QoL) was rejected.

The health status of patients in this study and their experience with the complete dentures are similar to those in previously published studies, suggesting an appropriate sample selection process (Awad et al., 2003; Wolff et al., 2003; Anastassiadou and Robin Heath, 2006). Stability of the maxillary and mandibular dentures was the factor that contributed most to determining patient QoL. The relationship between mandibular complete denture retention and patient QoL also approached significance ($p = 0.092$). This finding was expected, as retention and stability are interrelated. It is possible that the relationship between retention of the mandibular denture and patient QoL would become significant with an increased sample size.

In general, patients who seek complete denture treatment have lower OHRQoL scores compared to dentate older people and patients receiving different modalities of prosthetic treatment (Allen and McMillan, 2003; John et al., 2004). This observation can be attributed to the fact that patients with complete dentures usually encounter difficulties in performing home tasks, social work, and leisure activities (Reisine, 1988). Many studies have shown that providing conventional complete dentures to edentulous patients can improve their appearance, chewing ability, social function, and OHRQoL (Agerberg and Carlsson, 1981; Carlsson, 1998; Allen and McMillan, 2003; Adam, 2006). More specifically, stable conventional complete dentures that allow patients to achieve a satisfactory chewing capacity have a positive impact on their QoL (de Souza e Silva et al., 2009). Conversely, an ill-fitting denture negatively affects the patient’s ability to eat, talk, and smile freely (Sheiham and Croog, 1981).

Therefore, clinicians should effectively utilize the biomechanical considerations that influence denture stability, such as muscle tonus, neuromuscular coordination, and tongue, cheek, lip, and jaw to fabricate conventional complete dentures (Chaytor, 2004). In cases of severe resorption of the alveolar ridge, preprosthetic surgery (e.g., sulcus deepening, vestibuloplasty, and ridge augmentation) can be used to provide an optimized denture-bearing area. However, due to the introduction of dental implants, this procedure is not as commonly used. The body of evidence regarding the efficacy of implant

| History of complete dentures | 28 (87.5)                        |
| Yes             | 28 (87.5)                                |
| No              | 4 (12.5)                                 |

The mean total score in denture quality evaluations was 5.63 ± 1.50. Clinicians rated the clinical quality of the dentures as 80.3% satisfactory across the seven items scored. Esthetic quality (lip support and lower lip line) and quality of the maxillary denture (stability and retention) were rated significantly higher than the quality of the maxillary and mandibular dentures was the factor that contributed most to determining patient QoL.

OHIP-20 scores were lower in patients who seek complete denture treatment than in dentate older people and patients receiving different modalities of prosthetic treatment (Allen and McMillan, 2003; John et al., 2004). This observation can be attributed to the fact that patients with complete dentures usually encounter difficulties in performing home tasks, social work, and leisure activities (Reisine, 1988). Many studies have shown that providing conventional complete dentures to edentulous patients can improve their appearance, chewing ability, social function, and OHRQoL (Agerberg and Carlsson, 1981; Carlsson, 1998; Allen and McMillan, 2003; Adam, 2006). More specifically, stable conventional complete dentures that allow patients to achieve a satisfactory chewing capacity have a positive impact on their QoL (de Souza e Silva et al., 2009). Conversely, an ill-fitting denture negatively affects the patient’s ability to eat, talk, and smile freely (Sheiham and Croog, 1981). Therefore, clinicians should effectively utilize the biomechanical considerations that influence denture stability, such as muscle tonus, neuromuscular coordination, and tongue, cheek, lip, and jaw to fabricate conventional complete dentures (Chaytor, 2004). In cases of severe resorption of the alveolar ridge, preprosthetic surgery (e.g., sulcus deepening, vestibuloplasty, and ridge augmentation) can be used to provide an optimized denture-bearing area. However, due to the introduction of dental implants, this procedure is not as commonly used. The body of evidence regarding the efficacy of implant
treatments for improving the stability and retention of complete dentures and the patient’s QoL continues to grow (Naert et al., 1988; Burns et al., 1995; Alwad et al., 2000, 2003; Walton et al., 2009; Alwada et al., 2009). Dental implants should be considered, particularly for patients who psychologically cannot adapt to being edentulous and for elderly patients receiving their first complete denture set at an advanced age when neuromuscular adaptation is diminished.

Although the evidence is not yet conclusive, an array of factors in addition to the technical quality of the dental treatment are thought to play a role in determining the patient QoL. Other factors that have been reported to affect perceived QoL include age, tooth loss, cultural differences (Steele et al., 2004), the patient’s anxiety toward dental treatment (McGrath and Bedi, 2004), the ability of the patient to cope with the stress of dental treatment (Heydecke et al., 2004), and the presence of prosthetic stomatitis (Perea et al., 2013). Hence, in addition to professional considerations and socioeconomic status, the concerns and demands of the patient are key when considering prosthetic therapy (Budtz-Jorgensen, 2001). Clinicians should allow sufficient time during dental visits to listen attentively to the patient’s complaints, concerns, and expectations. Addressing the needs of the patient will most likely lead to their satisfaction and positively affect their QoL. Allen and McMillan reported that the QoL score was only moderately improved in patients who requested

### Table 4 The OHIP-20 scores.

| Have you had...? | N (%) of patients | Mean ± SD<sup>v</sup> |
|-----------------|-------------------|----------------------|
| Difficulty chewing any foods because of problems with your teeth, mouth or dentures? | 7 (21.2) 5 (18.2) 3 (9.1) 2 (6.1) 4 (12.1) 11 (33.3) | 3.3 ± 2.05 |
| Trouble pronouncing any words because of problems with your teeth, mouth or dentures? | 3 (9.1) 1 (6.1) 4 (12.1) 6 (18.2) 7 (21.2) | 11 (33.3) 2.73 ± 1.68 |
| Food catching in your teeth or dentures? | 5 (15.2) 2 (9.1) 4 (12.1) 6 (18.2) 2 (6.1) | 13 (39.4) 2.91 ± 1.89 |
| Feeling that your dentures have not been fitting properly? | 6 (18.2) 1 (6.1) 4 (12.1) 2 (6.1) 10 (30.3) 9 (27.3) | 2.94 ± 1.87 |
| Painful aching in your mouth? | 4 (12.1) 2 (9.1) 2 (6.1) 8 (24.2) 4 (12.1) | 12 (36.4) 2.76 ± 1.77 |
| Uncomfortable experience to eat because of problems with your teeth, mouth or dentures? | 9 (27.3) 2 (9.1) 4 (12.1) 2 (6.1) 4 (12.1) | 11 (33.3) 3.33 ± 2.1 |
| Sore spots in your mouth? | 1 (3.0) 2 (9.1) 3 (9.1) 6 (18.2) | 7 (21.2) 13 (39.4) 2.36 ± 1.48 |
| Uncomfortable dentures? | 3 (9.1) 2 (9.1) 6 (18.2) 5 (15.2) 11 (33.3) 5 (15.2) | 2.7 ± 1.40 |
| Worries caused by dental problems? | 3 (9.1) 5 (18.2) 15 (52.1) 1 (3.0) 4 (12.1) | 14 (42.4) 2.82 ± 1.89 |
| Been self-conscious because of your teeth, mouth or dentures? | 6 (18.2) 3 (12.1) 1 (3.0) 3 (9.1) 1 (3.0) 18 (54.5) | 4.3 ± 2.1 |
| To avoid eating some foods because of problems with your teeth, mouth or dentures? | 6 (18.2) 3 (12.1) 3 (9.1) 4 (12.1) | 7 (21.2) 9 (27.3) 3.88 ± 1.9 |
| Been unable to eat with your dentures because of problems with them? | 3 (9.1) 6 (21.2) 3 (9.1) 5 (15.2) | 6 (18.2) 9 (27.3) 3.94 ± 1.77 |
| To interrupt meals because of problems with your teeth, mouth or dentures? | 5 (15.2) 3 (12.1) 4 (12.1) 3 (9.1) 9 (27.3) | 8 (24.2) 3.06 ± 1.82 |
| Been upset because of problems with your teeth, mouth or dentures? | 2 (6.1) 5 (18.2) 3 (9.1) 8 (24.2) 4 (12.1) | 10 (30.3) 2.91 ± 1.66 |
| Been a bit embarrassed because of problems with your teeth, mouth or dentures? | 6 (18.2) 2 (9.1) 1 (3.0) 3 (9.1) | 1 (3.0) 19 (57.6) 2.27 ± 1.91 |
| Avoided going out because of problems with your teeth, mouth or dentures? | 0 (0) 2 (9.1) 2 (9.1) 4 (12.1) | 4 (12.1) 20 (60.6) 1.91 ± 1.36 |
| Been less tolerant of your spouse or family because of problems with your teeth, mouth or dentures? | 1 (3.0) 1 (6.1) 2 (6.1) 2 (6.1) | 2 (6.1) 24 (72.7) 1.76 ± 1.44 |
| Been a bit irritable with other people because of problems with your teeth, mouth or dentures? | 0 (0) 2 (9.1) 1 (3.0) 1 (3.0) 3 (9.1) 25 (75.8) | 1.61 ± 1.27 |
| Been unable to enjoy other people’s company as much because of problems with your teeth, mouth or dentures? | 3 (9.1) 4 (15.2) 2 (6.1) 4 (12.1) 1 (3.0) | 18 (54.5) 2.52 ± 1.89 |
| Felt that life in general was less satisfying because of problems with your teeth, mouth or dentures? | 2 (6.1) 3 (12.1) 2 (6.1) 3 (9.1) 6 (18.2) 16 (48.5) | 2.33 ± 1.69 |

<sup>v</sup> Scale ranges from 1 (“never”) to 6 (“always”).

### Table 5 Correlation between denture quality parameters and OHIP-20.

| Denture quality parameter | Correlation | p-Value |
|---------------------------|-------------|---------|
| Esthetic lip support      | 0.15        | 0.440   |
| Esthetic lower lip line   | −0.09       | 0.628   |
| Stability of maxillary denture | −0.47       | 0.009<sup>x</sup> |
| Stability of mandibular denture | −0.45       | 0.0023<sup>x</sup> |
| Retention of maxillary denture | −0.26       | 0.169   |
| Retention of mandibular denture | −0.34       | 0.092   |
| Occlusion                 | −0.21       | 0.250   |

<sup>x</sup> Point-biserial correlation coefficient.

Correlations larger than r = 0.40 are statistically significant at p < .05.
an implant-supported overdenture but could not receive the requested treatment (Allen and McMillan, 2003). However, the QoL for patients who received their treatment of choice was significantly improved. These findings further affirm the significance of identifying and addressing the patient’s concerns and demands as an integral part of any dental treatment.

5. Conclusion

The stability of the maxillary and mandibular dentures is the denture quality parameter that can most significantly affect patient quality of life.

Financial support

None.

Conflict of interest

The authors have no conflict of interest to declare.

Acknowledgements

The authors wish to express their gratitude to the dental students at the College of Dentistry, King Saud University for their help in patients’ recruitment. Many thanks to Mr. N. Al-Mafleh for his contribution to statistical analysis.
