Abstract

We study the (anti)kaon nucleon interaction in the Skyrme model. The kaon field is introduced as a fluctuation around the rotating Skyrmion for the nucleon. As an extension of our previous work, we study scattering states and examine phase shifts in various kaon-nucleon channels. Then we study the interaction, where we find that it consists of central and spin-orbit components for isospin channels, $I = 0, 1$, with energy dependence and nonlocality. The interaction is then fitted to a Shrödinger equivalent local potential for s- and p-waves.

I. INTRODUCTION

The kaon-nucleon system is one of interesting systems in hadron physics. It is considered that the anti-kaon and nucleon (\(\bar{K}N\)) interaction is strongly attractive. Based on the properties of the \(\bar{K}N\) strong attraction, a lot of discussions for the \(\bar{K}N\) systems have been done. One example is the \(\Lambda\) (1405) resonance known as a candidate of the \(\bar{K}N\) quasi-bound state \([1, 2]\) whose properties cannot be explained easily by a simple quark model \([3]\). Another example is the kaonic nucleus where the anti-kaon is bound to a nucleus by a strong attraction between them. It is expected that, because of the strong attraction, the structure of the kaonic nucleus is largely modified from normal nuclei \([4, 5]\). In such discussions, kaon-nucleon interaction is obviously the most important input.

In this article, we first discuss the phase shift for kaon-nucleon scattering states by a modified bound state approach proposed in the previous work \([6]\). Our approach is based on the bound state approach which is proposed by Callan and Klebanov \([7, 8]\). In the original approach, the kaon is introduced as a fluctuation around the hedgehog configuration, and then the kaon-hedgehog system is collectively quantized as hyperons. On the other hand, in our approach, we first generate the nucleon by quantizing the hedgehog soliton, and then introduce the kaon fluctuation around the physical nucleon. The difference of the Callan-Klebanov and our approaches is the ordering of projection and variation. The Callan-Klebanov approach corresponds to the projection after variation, while ours to the variation after projection. In the previous paper, we have investigated \(\bar{K}N\) bound states. As a result, we found one bound state for the \(\bar{K}N\) (\(J^P = 1/2^-, I = 0\)) channel with a binding energy of order ten MeV corresponding to \(\Lambda\) (1405).

Secondly, we derive a Schrödinger equivalent local potential for the kaon and nucleon. The resulting potential is fitted by Gaussian type functions which is convenient for the study of few-body nuclear systems with the anti-kaon. In general, the kaon-nucleon potential has four components; the isospin independent and dependent central terms, and spin-orbit terms (LS terms). These complete all possible components for the pseudo-scalar and iso-scalar kaon and the spinor and iso-spinor nucleon. Furthermore, the interaction is energy dependent and nonlocal.

We organize the paper as follows. In the next section, we briefly review our approach which we have constructed in the previous work. In Sec. III, we discuss phase shifts for kaon nucleon scattering states with lower kaon partial waves. In Sec. IV, we derive various components of the potential and perform fitting to Gaussian type functions. Then we discuss scaling properties of the potential associated with the scaling properties of soliton solutions. In the end, we summarize the present work and discuss further studies.

II. FORMALISM

In this section, we review our modified bound state approach. Detailed discussions have been done in Ref. \([6]\). Let us start with the following Lagrangian for the SU(3)-valued field.
\[ U = U(r) \]
\[ L = \frac{1}{16} F_\pi^2 \text{tr} \left( \partial_\mu U \partial^\mu U^\dagger \right) + \frac{1}{32 e^2} \text{tr} \left[ (\partial_\mu U) U^\dagger, (\partial_\mu U) U^\dagger \right]^2 + L_{SB} + L_{WZ}, \tag{1} \]

where the first and second terms are the Skyrme Lagrangians \[ 9–11 \] and the third term is
the symmetry breaking term due to finite masses of the SU(3) pseudo-scalar mesons \[ 12, 13 \]

\[ L_{SB} = \frac{1}{48} F_\pi^2 \left( m_\pi^2 + 2 m_K^2 \right) \text{tr} \left( U + U^\dagger - 2 \right) + \frac{\sqrt{3}}{24} \left( m_\pi^2 - m_K^2 \right) \text{tr} \left[ \lambda_8 \left( U + U^\dagger \right) \right]. \tag{2} \]

In this paper, we treat the pion as a massless particle while the kaon as massive one. We call
these three terms in Eq. (1) as normal Lagrangians in this paper. The last term in Eq. (1)
is the contribution of the chiral anomaly called the Wess-Zumino term given by \[ 14–16 \]

\[ L_{WZ} = -\frac{i N_c}{240 \pi^2} \int d^5 x \varepsilon^{\mu \nu \alpha \beta \gamma} \text{tr} \left[ \left( U^\dagger \partial_\mu U \right) \left( U^\dagger \partial_\nu U \right) \left( U^\dagger \partial_\alpha U \right) \left( U^\dagger \partial_\beta U \right) \left( U^\dagger \partial_\gamma U \right) \right], \tag{3} \]

where \( N_c \) is the number of colors, \( N_c = 3 \).

The Lagrangian Eq. (1) contains three parameters; the pion decay constant, \( F_\pi \), the
Skyrme parameter, \( e \), and the mass of the kaon, \( m_K \). Here, we keep \( m_K \) at the experimental
value, 495 MeV, and we consider three parameter sets for \( F_\pi \) and \( e \). We will show them in
the next section.

To study the interaction of the kaon with the physical nucleon, we introduce the ansatz,

\[ U = A(t) \sqrt{U_\pi A^\dagger(t)} U_K A(t) \sqrt{U_\pi A^\dagger(t)}, \tag{4} \]

where \( A(t) \) is an isospin rotation matrix, \( U_\pi \) is the Hedgehog pion field with the soliton
profile function, \( F(r) \),

\[ U_\pi = \begin{pmatrix} \xi^2 & 0 \\ 0 & 1 \end{pmatrix}, \quad \xi^2 = \exp \left[ i F(r) \tau \cdot \hat{r} \right], \tag{5} \]

and

\[ U_K = \exp \left[ \frac{2 \sqrt{2} i}{F_\pi} \begin{pmatrix} 0 & K \\ K^\dagger & 0 \end{pmatrix} \right], \quad K = \begin{pmatrix} K^+ \\ K^0 \end{pmatrix}. \tag{6} \]

As discussed in Ref. \[ 6 \], the ansatz Eq. (4) describes the kaon fluctuation around the rotating
hedgehog soliton, and differs from the one of Callan and Klebanov for the kaon around the
static hedgehog soliton \[ 7, 8 \].

Now we derive the equation of motion for the kaon field. To do that, we first substitute
our ansatz Eq. (4) for the Lagrangian Eq. (1), and then we expand \( U_K \) up to second order
of the kaon field, \( K \). As a result, we obtain the following Lagrangian for the kaon-nucleon
system,

\[ L = L_{SU(2)} + L_{KN}, \tag{7} \]
\[
L_{KN} = (D_\mu K)^\dagger D^\mu K - K^\dagger a_\mu^\dagger a^\mu K - m_K^2 K^\dagger K
+ \frac{1}{(e_F^2)^2} \left\{ -K^\dagger K \text{tr} \left[ \partial_\mu \bar{U} \bar{U}^\dagger, \partial_\nu \bar{U} \bar{U}^\dagger \right] \right\}^2
- \frac{1}{2} (D_\mu K)^\dagger D^\mu K \text{tr} \left( a_\nu^\dagger \partial^\nu \bar{U} \right)
+ 6 (D_\nu K)^\dagger [a^\nu, a^\mu] D_\mu K \right\}
+ \frac{3i}{F_\pi^2} B^\mu \left[ (D_\mu K)^\dagger K - K^\dagger (D_\mu K) \right],
\]

where the covariant derivative is defined as \( D_\mu = \partial_\mu + v_\mu \), and the vector and axial vector currents are

\[
v_\mu = \frac{1}{2} \left( \bar{\tilde{\xi}}^\dagger \partial_\mu \tilde{\xi} + \tilde{\xi} \partial_\mu \bar{\tilde{\xi}}^\dagger \right),
\]

\[
a_\mu = \frac{1}{2} \left( \bar{\tilde{\xi}}^\dagger \partial_\mu \tilde{\xi} - \tilde{\xi} \partial_\mu \bar{\tilde{\xi}}^\dagger \right).
\]

In these equations, the tilded quantities are rotating;

\[
\tilde{U} = A(t) \bar{\xi}^2 \Lambda^\dagger(t), \quad \tilde{\xi} = A(t) \xi \Lambda^\dagger(t),
\]

as required by our ansatz Eq. (4). Finally, the last term of Eq. (8) is derived from the Wess-Zumino term with the baryonic current [17], \( B_\mu \).

Next, we decompose the kaon field into the two-component isospinor and spatial wave functions, and expand the latter into partial waves by the spherical harmonics, \( Y_{lm}(\hat{r}) \),

\[
\begin{pmatrix} K^+ \\
K^0
\end{pmatrix} = \psi_I K(t, r)
\rightarrow \psi_I K(r) \exp (-iEt),
\]

\[
K(r) = \sum_{\alpha lm} C_{\alpha lm} Y_{lm}(\hat{r}) \ k^\alpha_I(r),
\]

where \( \psi_I \) is the two component isospinor.

Finally, taking a variation with respect to the kaon wave function, we obtain the equation of motion for each partial wave, \( k^\alpha_I(r) \),

\[
-\frac{1}{r^2} \frac{d}{dr} \left( r^2 h(r) \frac{dk^\alpha_I(r)}{dr} \right) - E^2 f(r) k^\alpha_I(r) + (m_K^2 + V(r)) k^\alpha_I(r) = 0,
\]

where \( h(r) \) and \( f(r) \) are functions depending on the profile function, \( F(r) \), and \( E \) is the energy of the kaon including the rest mass of the kaon. The last term in Eq. (14), \( V(r) \), is the kaon-nucleon interaction term. In Appendix [A] we show explicit forms of each term in Eq. (14).
TABLE I: Parameter sets and binding energy (B.E.)

|             | $F_\pi$ [MeV] | $e$  | B.E. [MeV] |
|-------------|---------------|------|------------|
| Parameter set A | 205           | 4.67 | 20.6       |
| Parameter set B | 186           | 4.82 | 32.2       |
| Parameter set C | 129           | 5.45 | 81.3       |

III. SCATTERING STATES

In this section, we discuss phase shifts for the s- and p-wave kaon nucleon scattering states. As we mentioned in the previous section, in this paper, we consider three parameter sets for $F_\pi$ and $e$ shown in the Table I. For the reason that we discuss later, these parameter sets reproduce the same moment of inertia such that the mass splitting of the nucleon and delta becomes the physical value.

- Parameter set A: we employ the pion decay constant slightly larger than the physical one. This is motivated by that the kaon decay constant, $F_K$, is larger than the pion one ($F_K = 227$ MeV), and that we are interested in a physical system of the pion and kaon. Therefore we choose $F_\pi = 186 \times 1.1 = 205$ MeV. The Skyrme parameter, $e$, is then fixed to reproduce the $N\Delta$ mass splitting together with the above $F_\pi$ value.

- Parameter set B: this is adjusted to fit the $N\Delta$ mass splitting with $F_\pi$ fixed at the experimental value.

- Parameter set C: this is proposed by Adkins, Nappi, and Witten [17], which reproduces the observed masses of the nucleon and the delta.

For the parameter set A, there is one bound state for the $I = 0$ channel with the binding energy 20.6 MeV while, for the $I = 1$ channel, no bound state exists. There is one bound state for the $I = 0$ and $I = 1$ channels with the sets B and C [28]. For $KN$ channel, the kaon and nucleon does not form a bound state due to the strong repulsion by the Wess-Zumino term for three parameter sets.

We have calculated phase shifts for the s- and p-wave kaon nucleon scattering states for all parameter sets. However, for realistic situations of kaon and nucleon systems, it turns out that the use of the physical pion decay constant is important. Therefore, in the following discussions, we will present in most cases the results of using the parameter sets A and B.

First we show in Fig. [1] phase shifts for s-wave scatterings with various channels as functions of the kinetic energy $\varepsilon$, which is defined by $E = m_K + \varepsilon$. For the set A (left), the phase shift of the $\bar{K}N (I = 0)$ channel starts from $\pi$ at $\varepsilon = 0$, reflecting the fact that there is one bound state. For the $\bar{K}N (I = 1)$ channel, there is not a bound state but it shows attractive nature as the positive phase shifts indicate. For the $KN$ scattering, both $I = 0$ and $I = 1$ channels are weakly repulsive but the $I = 1$ channel is stronger.
For the set B (right), $\bar{K}N$ channels allow a bound state for both $I = 0$ and $I = 1$. The bound state of $I = 1$ is, however, very shallow indicating that the attractive interaction is weaker than in the $I = 0$ channel. The $I = 1$ bound state disappears by slightly increasing the pion decay constant as chosen in the parameter set A. We may further attempt fine tuning of the parameters, but we will not do this because our present model contains only $K N$ channels. Physically, the inclusion of the $\pi \Sigma$ channels is very important, which we will do in the future.

From Fig. 1 we find that the strength of repulsion for $KN$ and attraction for $\bar{K}N$ are stronger for the set B than for the set A. This reflects the fact that the obtaining potential is approximately proportional to $1/F_\pi^2$ as the Weinberg-Tomozawa theorem implies [18, 19].

FIG. 1: Phase shifts for the kaon-nucleon scattering state with $J^P = 1/2^-$ for the parameter sets A (left) and B (right).

FIG. 2: The phase shifts for the $\bar{K}N(J^P = 1/2^-, I = 0)$ channel with the three parameter sets A, B, and C.
To complete the discussions up to here, we show the phase shifts for all parameter sets A, B, and C for the $\bar{K}N \,(J^P = 1/2^-, \, I = 0)$ channel in Fig. 2. In this figure, we can find that the attraction between the anti-kaon and nucleon becomes stronger in the order of the set A, B, and C, which is consistent with the properties of the $\bar{K}N$ bound states shown in Table. [1]

Next, in Fig. 3, we have shown the phase shifts for p-waves, first for $J^P = 3/2^+$ channels. In both sets A and B, the phase shifts show the attractive and repulsive behaviors for $\bar{K}N$ and $KN$ channels, respectively. However, the strength of them are weaker than those of the s-wave. The phase shifts in the $\bar{K}N$ channels show that the $I = 1$ channel is more attractive than the $I = 0$ one due to the stronger isospin-dependent LS force in the $I = 1$ channel.

For the other LS partner of $J^P = 1/2^+$ channel, the interaction shows a strong attraction as proportional to $1/r^2$. Because of this, the system becomes unstable and physically meaningful solutions are not allowed. We consider that it is related to the hedgehog structure, but physical meaning is not yet clarified.

Finally, let us evaluate the scattering length, $a$, for the $\bar{K}N \,(J^P = 1/2^-)$ scattering state which is defined by

$$a = - \lim_{k \to 0} \frac{\tan \delta(k)}{k},$$

where $k$ is the wave number and $\delta(k)$ is the phase shift. From this equation, we have obtained $a_0 = 1.56 \text{ fm}$ and $a_1 = -3.38 \text{ fm}$ for the $\bar{K}N$ scattering with isospin 0 and 1 channels, respectively. As a result, we have $a_{\bar{K}N} = -0.91 \text{ fm}$ as the $\bar{K}N$ scattering length. These values are larger than experimental values and other theoretical calculations [20,24]. In the present paper, we will not make further quantitative discussions because the inclusion of the $\pi \Sigma$ channels is needed for more realistic comparison.
IV. POTENTIAL

In this section, we investigate the $\bar{K}N$ potential in detail. Numerical results are then fitted to a simple functional form which are useful for various applications to the study of $\bar{K}$-nucleon systems. First, we consider the potential for the parameter set A. For the sets B and C, we discuss them with scaling rules from the set A to the sets B and C.

A. Derivation and classification of the potential

Let us start with the equation of motion Eq. (14) in the following Schrödinger-like form with the potential $U(r)$ in units of MeV,

$$\frac{1}{m_K + E} \frac{d}{dr} \left( r^2 \frac{dk_1^\alpha (r)}{dr} \right) + U(r) k_1^\alpha (r) = \varepsilon k_1^\alpha (r),$$

(16)

where $E = m_K + \varepsilon$, and

$$U(r) = -\frac{1}{m_K + E} \left[ \frac{h(r) - 1}{r^2} \frac{d}{dr} \left( r^2 \frac{d}{dr} \right) + \frac{dh(r)}{dr} \frac{d}{dr} \right] - \frac{(f(r) - 1)}{m_K + E} \frac{E^2}{m_K + E} + \frac{V(r)}{m_K + E}.$$

(17)

The potential $U(r)$ has the following properties [6]; it is nonlocal and depends on the energy of the kaon. Second, it contains isospin independent and dependent central terms and spin-orbit (LS) terms. Finally, there are repulsive components proportional to $1/r^2$ at short distances.

Because this expression contains the derivative operators, we define the equivalent local potential $\tilde{U}(r)$ with the kaon partial wave function, $k_1^\alpha (r)$,

$$\tilde{U}(r) \equiv \frac{U(r) k_1^\alpha (r)}{k_1^\alpha (r)}.$$

(18)

This definition, however, can not be used when the wave function becomes zero at nodal points. We may avoid this problem by using a bound state for the isospin $I = 0$ $\bar{K}N$ channel which allows one bound state, and for other channels by using a scattering state with a small energy such that the first node of the wave function appears at a large $r$ where the potential is sufficiently suppressed. In the following, we show the results for the scattering energy $\varepsilon = 27$ MeV, while we have confirmed that results do not change as long as the scattering energy is small.

As mentioned already, the equivalent local potential $\tilde{U}(r)$ has four kinds of components. Here, we decompose them further into seven components reflecting different origins of the potential,

$$\tilde{U}(r) = \tilde{U}_0^c (N, r) + \tilde{U}_0^c (N, r) I_{KN}$$

$$+ \tilde{U}_0^{LS} (N, r) J_{KN} + \tilde{U}_0^{LS} (N, r) J_{KN} I_{KN},$$

$$+ \tilde{U}_0^{WZ} (WZ, r) + \tilde{U}_0^{WZ} (WZ, r) J_{KN},$$

$$+ \tilde{U}_0 (r),$$

(19)
where superscripts, $c$ and $LS$, stand for the central and spin-orbit (LS) forces, respectively, and subscripts, 0 and $\tau$ are for isospin independent and dependent components, respectively. The arguments, $N$ and $WZ$, indicate the terms derived from the normal terms of the Skyrme Lagrangian and the Wess-Zumino term, respectively. In Eq. (19), we have defined $I_{KN}$ and $J_{KN}$ as $I_{KN} = I^K \cdot I^N$ and $J_{KN} = L^K \cdot J^N$, respectively. The former, $I_{KN}$, corresponds to the product of the isospin operator for the kaon and the nucleon and the latter, $J_{KN}$, to the product of the angular momentum of the kaon and the spin of the nucleon. The last term in Eq. (19), $\tilde{U}_l(r)$, is the centrifugal force of the kaon. Because the Wess-Zumino term corresponds physically to the $\omega$-meson exchange, that is the isoscalar particle exchange [14–16], it has no isospin dependent contributions in Eq (19).

The seven potential components have energy dependence, for which we make a linear approximation in terms of $\Delta E \equiv \varepsilon/2m_K$,

\[ \tilde{U}(r) \approx \tilde{U}(r) + \frac{\partial \tilde{U}(r)}{\partial \varepsilon} \Delta E \equiv u(r) + v(r) \Delta E. \]  

We then fit all the components of $u(r)$ and $v(r)$ by several Gaussian type functions,

\[ G_{-2}(r) = C_{-2} \frac{1}{r^2/R_{-2}^2} \exp \left( -\frac{r^2}{R_{-2}^2} \right) \]  
\[ G_0(r) = C_0 \exp \left( -\frac{r^2}{R_0^2} \right) \]  
\[ G_2(r) = C_2 \frac{r^2}{R_2} \exp \left( -\frac{r^2}{R_2^2} \right) , \]

as summarized in Table I. For example, the isospin independent components of the central terms derived from the normal Skyrme Lagrangian, $u_0^c(N,r)$ and $v_0^c(N,r)$, are fitted by the three functions, $G_{-2}(r)$, $G_0(r)$, and $G_2(r)$. The first one, $G_{-2}(r)$, is the Gaussian divided by $r^2$ which is needed to reproduce a repulsive behavior in the short range, and the second and third are the Gaussians with polynomial of $r^0$ and $r^2$.

For the centrifugal term, we have fitted as follows,

\[ \tilde{U}_l(r) = \frac{l(l+1)}{2m_Kr^2} \left[ G_0^{(1)}(r) + G_0^{(2)}(r) + 1 \right] , \]  

where $l$ and $m_K$ are the angular momentum and the mass of the kaon, respectively. At short and middle distances, the centrifugal term deviates from the ordinary one of $1/r^2$ due to background fields of the hedgehog soliton. However, at long distances, it reduces to the ordinary form.

**B. Numerical fitting**

In this subsection, we compare numerically obtained potentials with those fitted by the Gaussian forms for each component in Fig. 4–10. The fitting parameters are shown in Appendix B.
| Isospin | Fitting function |
|---------|------------------|
| Central |                 |
| indep.  | \( u_0(N, r) + v_0(N, r) \Delta_E \) |
|         | \( G_{-2}(r) + G_0(r) + G_2(r) \) |
|         | \( u_0(WZ, r) + v_0(WZ, r) \Delta_E \) |
|         | \( G_0^{(1)}(r) + G_0^{(2)}(r) \) |
| dep.    | \( u_c(N, r) + v_c(N, r) \Delta_E \) |
|         | \( G_0(r) + G_2(r) \) |
| LS      |                 |
| indep.  | \( u_0^L(N, r) + v_0^L(N, r) \Delta_E \) |
|         | \( G_0^{(1)}(r) + G_0^{(2)}(r) \) |
|         | \( u_0^L(WZ, r) + v_0^L(WZ, r) \Delta_E \) |
|         | \( G_0^{(1)}(r) + G_0^{(2)}(r) \) |
| dep.    | \( u_c^L(N, r) + v_c^L(N, r) \Delta_E \) |
|         | \( G_{-2}^{(1)}(r) + G_{-2}^{(2)}(r) \) |
| Centrifugal force | \( u_l(r) + v_l(r) \Delta_E \) |
|         | \[ G_0^{(1)}(r) + G_0^{(2)}(r) + 1 \] / \( 2m_Kr^2 \) |

TABLE II: Various components of the \( \vec{K}N \) potential and the corresponding fitted functions. The functions \( u(r) \) and \( v(r) \) are for energy independent and dependent components with upper and lower indices as explained in the text. The fitted functions \( G_n(r) \) are also defined in the text, Eq. (21), (22), and (23). Superscripts, (1) and (2) of \( G_n^{(1)}(r) \), indicate that fitting parameters are different for the functions.

We have treated both ranges, \( R_i \), and strengths, \( C_i \), as fitting parameters. Practically, we have performed the fitting as follows; first, we have fitted both range and strength parameters for the energy independent components because they are dominant contributions. Then, we have determined the strength parameters of the energy dependent components with the same range parameters as the energy independent ones. This is because we consider that the energy independent and dependent components have the same physical origin, if based on a boson exchange picture.

Let us now make detailed discussions for each component below. We concentrate on the \( \vec{K}N \) potentials but we can estimate the \( KN \) ones with taking into account the difference of the quantum numbers. However, due to the nonlocality, we need to solve the equation of motion to derive more accurate potentials.
FIG. 4: Comparisons between the numerically obtained and the Gaussian-fitted potentials for \( u_0^c(N, r) \) (left) and \( v_0^c(N, r) \) (right) for the s-wave (upper panels) and p-wave (lower panels) components.

FIG. 5: Comparisons between the numerically obtained and the Gaussian-fitted potentials for \( u_0^c(WZ, r) \) (left) and \( v_0^c(WZ, r) \) (right).
FIG. 6: Comparisons between the numerically obtained and the Gaussian-fitted potentials for $u_c^c(N, r)$ (left) and $v_c^c(N, r)$ (right).

FIG. 7: Comparisons between the numerically obtained and the Gaussian-fitted potentials for $u_0^{LS}(N, r)$ (left) and $v_0^{LS}(N, r)$ (right).

FIG. 8: Comparisons between the numerically obtained and the Gaussian-fitted potentials for $u_0^{LS}(WZ, r)$ (left) and $v_0^{LS}(WZ, r)$ (right).
From Figs. 4 – 10 we can see that the fitting is done by the Gaussian forms in a good manner. We find that four components, $U_0(WZ, r)$, $U_0^{LS}(N, r)$, $U_0^{LS}(WZ, r)$, and $U_T^{LS}(N, r)$, are fitted by a single Gaussian function, $G_0(r)$ or $G_{-2}(r)$, but with different ranges which are indicated by the superscript, while the others, $U_2^c(N, r)$, $U_2^c(N, r)$, and $U_1(r)$, are fitted with the different forms. We consider that the reason behind is that the former originates from a simple physical mechanism while the latte from complex one.

From now on, we make discussions for each component below.

- Figure 4
  For the s-wave channel, as shown in the upper left panel, we find that there is an attractive pocket whose depth is around 100 MeV in the middle range and a repulsive core at a short distances in the energy independent potential, $u_0^c(N, r)$. Contrary, the energy dependent components, $v_0^c(N, r)$, behaves rather monotonically with an attraction as proportional to $1/r^2$. Turning to the p-wave potential as shown in the lower
panel, energy independent component is attractive as proportional to $1/r^2$, while the energy dependent one behaves similarly to the s-wave energy independent component, but with shorter range. We can also see that the energy independent and dependent components behave in a quite different manner between the s- and p-wave channels. This is because of the nonlocal contributions of them. To see that, we first separate the potentials, $u_0^c(N, r)$ and $v_0^c(N, r)$, into the local and nonlocal contributions for the two channels,

$$u_0^c(N, r) = u_0^c(N, \text{local}, r) + u_0^c(N, \text{non}, r) \quad (25)$$

$$v_0^c(N, r) = v_0^c(N, \text{local}, r) + v_0^c(N, \text{non}, r), \quad (26)$$

where the arguments local and non stand for the local and nonlocal contributions, respectively. Then, we have numerically calculated the nonlocal contributions for the s- and p-waves and shown the results in Fig. 11 where the s-wave components are plotted by solid line and the p-wave one by dashed line. We can see that the nonlocal contributions are quite different between them.

![Graph showing nonlocal contributions for s- and p-waves](image)

**FIG. 11:** Nonlocal components of $u_0^c(N, r)$ (left) and $v_0^c(N, r)$ (right) for the s- and p-waves (solid and dashed lines, respectively).

- Figure 5

We can see that the energy independent and dependent components behave in a similar way but their strengths are very much different. To see this, the contribution is expanded with respect to $\Delta E = \varepsilon/2m_K$ as in Eq. (20),

$$U_0^c(WZ, r) = \frac{1}{m_K + E} \frac{3}{\pi^2 F_\pi^2} \frac{s^2}{r^2} F'(E - \frac{s^2}{\Lambda})$$

$$\propto \frac{1}{m_K + E} \left( E - \frac{s^2}{\Lambda} \right)$$

$$\simeq \left( \frac{1}{2} - \frac{1}{2m_K} \frac{s^2}{\Lambda} \right) + \left( \frac{1}{2} + \frac{1}{2m_K} \frac{s^2}{\Lambda} \right) \Delta E, \quad (27)$$

14
where the explicit expressions of $U_0^c(WZ, r)$ is shown in Eq. (A9). In Eq. (27), $\Lambda$ is a moment of inertia of the SU(2) hedgehog soliton and we define $s = \sin(F(r)/2)$. In our definition for $u_0^c(WZ, r)$ and $v_0^c(WZ, r)$, the first and second terms in Eq. (27) correspond to $u_0^c(WZ, r)$ and $v_0^c(WZ, r)$, respectively. Therefore, we obtain the following relations,

$$ u_0^c(WZ, r) \propto \frac{1}{2} - \frac{1}{2m_K} \frac{s^2}{\Lambda} \quad (28) $$

and

$$ v_0^c(WZ, r) \propto \frac{1}{2} + \frac{1}{2m_K} \frac{s^2}{\Lambda}. \quad (29) $$

From these equations, we find that the difference of the energy independent and dependent terms of the Wess-Zumino term is proportional to $s^2/\Lambda$. This explains the difference in the strengths shown in Fig. 5.

- Figures [6] and [7]
  In these figures, it is shown that the energy independent and dependent components become exactly the same. This should have been expected from the analytic form of the potential as shown in Eqs. (A10) and (A11), from which we can read explicitly,

$$ u(r) = v(r). \quad (30) $$

- Figures [8], [9] and [10]
  We can see that the strengths of the potentials are the same for each component but the sign is different between energy independent and dependent components. We can easily verify it from their explicit forms shown in Appendix A.

---

**FIG. 12: Total potentials for the $\bar{K}N\,(J^P = 1/2^-, I = 0)$ channel obtained from the bound state (left) and those for the $\bar{K}N\,(J^P = 3/2^+, I = 0)$ channel from a scattering state (right).**

Finally, we show the total potentials which are numerically obtained and fitted by the Gaussian forms in Fig. [12]. For the s-wave potential, we can see a repulsion at the short
distances which comes from the isospin independent central term of the normal Skyrme Lagrangian, $U^c_0 (N,r)$, as shown in Fig. 4. In the middle range, we find an attractive pocket which may generate the bound state. From Figs. 4–6 this attractive pocket is dominantly made by the attraction of the Wess-Zumino term.

From Fig. [2] we see that the behaviors of the potentials for the s-wave ($1/2^-$) and p-wave ($3/2^+$) are different; an attractive pocket vanishes for the p-wave. This is due to the strong repulsion of the LS and centrifugal components from the normal Lagrangian.

![FIG. 13: The phase shifts for the $\bar{K}N(J^P = 1/2^-, I = 0)$ channel obtained from the numerical and fitted potentials with the set A.](image)

So far we have seen that the fitting of the potential works well particularly for the local terms, while that for the nonlocal terms is not always the case as Fig. [11] shows. The nonlocal terms induce also energy dependence. To see this point, we check how the phase shifts are reproduced by the fitted potential as functions of the kinetic energy. In Fig. [13] we have compared the phase shifts calculated by the numerically obtained and fitted potentials. In the low energy region ($\varepsilon \lesssim 50$ MeV) where we consider that our approach works well, the two phase shifts agree well. Contrary, as the kinetic energy is getting larger, the difference of the phase shifts becomes larger, which is due to the nonlocal contributions. Therefore, our fitted potential can be used for practical calculations for low energy kaon and nucleon systems.

C. Scaling rules

So far, we have performed the potential fitting for the parameter set A. In this subsection, we consider it for the sets B and C by using the scaling property of the Skyrmion. In this way, various properties of the interaction will be better understood. First, we briefly review the
scaling rule in the Skyrme model and then show the scaling rules for the fitting parameters. Finally, we compare the numerically obtained potential and fitted one from the parameter set A by scaling rules.

The Skyrme model of massless pion has one dimensionful parameter, $F_\pi$, and one coupling constant, $e$. These are scaled out by introducing the standard unit where length is expressed by

$$y = eF_\pi r.$$  

(31)

By using this, soliton profiles for various $F_\pi$ and $e$ are related by a simple scale transformation to each other. In Fig. 14, we show the soliton profiles as functions of physical radial distance $r$ for the three parameter sets A, B, and C which are obtained from the standard profile function with the scaling rule Eq. (31). From Fig. 14, we find that the profile function for the set C is most extended among the three parameter sets; soliton size is inversely proportional to $eF_\pi$.

Having established the scaling rule for the soliton profile, let us investigate possible scaling rules for the kaon nucleon potential. First let us look at the relations among the parameter sets A, B, and C, and then we will discuss general cases.

As expected from dimensional argument, it is shown that the range parameters for the parameter sets A and B, for instance, are related by

$$R^B = \frac{\alpha^A}{\alpha^B} R^A.$$  

(32)

for all components of the potential. Here, we have defined $\alpha$ as $\alpha = eF_\pi$ and the superscripts $A$ and $B$ correspond to the parameter sets A and B, respectively, namely we take as follows, $\alpha^A = 4.67 \times 205$ MeV and $\alpha^B = 4.82 \times 186$ MeV.

Contrary, interaction strengths obey differently for different components.
For the components which does not include $G_{-2}$ as a fitting function, $U_0^c(WZ,r)$, $U_\tau^c(N,r)$, $U_0^{LS}(N,r)$, $U_0^{LS}(WZ,r)$, and $U_i(r)$, the strength parameters are scaled by the following rules,

$$C_i^B = C_i^A, \quad (i = -2, 0, 2).$$  \hspace{1cm} (33)

For the others ($U_0^c(N,r)$ and $U_\tau^{LS}(N,r)$), they obey the different rule as follows,

$$C_i^B = \left(\frac{\alpha_B}{\alpha_A}\right)^2 C_i^A, \quad (i = -2, 0, 2).$$ \hspace{1cm} (34)

In Fig. 15 and 16 we have shown the potentials for the same channel as in Fig. 12 for the parameter sets B and C. The s-wave potentials are calculated at the binding energies of the corresponding parameter set, namely, $\varepsilon = -32.2$ MeV for the set B and -81.3 MeV for the set C. The p-wave potential is calculated at the common scattering energy $\varepsilon = 27$ MeV. From Figs. 15 and 16 we find that the potentials for the parameter set A is scaled into the sets B and C with the scaling rules Eqs. (32) – (34) in a good manner.

![Numerical Fitting](image1.png)

**FIG. 15:** Total potentials for the $\bar{K}N$ ($J^P = 1/2^-, I = 0$) channel from the bound state (left) and the $\bar{K}N$ ($J^P = 3/2^+, I = 0$) channel from a scattering state (right) for the parameter set B which are derived from the potentials for the set A by the scaling rules Eqs. (32) – (34). The scattering energies are -32.2 and 27 MeV for s- and p-waves, respectively.

Finally, we consider general parameter sets. To do that, let us first observe that the potential contains terms with different $1/N_c$ behaviors, the one originates from the soliton profile (leading order term) and the one from the rotation (higher order term). The former is factored out by 1 in the standard unit, while the latter by $e^3 F_\pi \sim 1/N_c$ which is inversely proportional to the moment of inertia. Because of this, the scaling rules for different parameter sets of $F_\pi$ and $e$ differ for these two terms of different $1/N_c$ orders. For the case of set A, B and C, because the parameters are chosen to preserve the value $e^3 F_\pi$ unchanged, we have obtained a simple scaling rule as dictated by Eqs. (32) – (34). In general this is no longer the case and we have to consider the scaling rules for the leading and higher order...
FIG. 16: Total potentials for the $\bar{K}N (J^P = 1/2^-, I = 0)$ channel from the bound state (left) and the $\bar{K}N (J^P = 3/2^+, I = 0)$ channel from a scattering state (right) for the parameter set C which are derived from the potentials for the set A by the scaling rules Eqs. (32) – (34). The scattering energies are -81.3 and 27 MeV for s- and p-waves, respectively.

terms, separately. To see how the simple scaling rule holds generally, we introduce a new parameter set D which is taken as $F_\pi = 186$ MeV and $e = 5.85$. In this parameter set, we set the pion decay constant at the experimental value, while the Skyrme parameter at the $\rho\pi\pi$-coupling constant, $g_{\rho\pi\pi}$, determined from the KSRF relation [25, 26],

$$m_\rho^2 = \frac{g_{\rho\pi\pi} F_\pi^2}{2}, \quad (35)$$

where $m_\rho = 770$ MeV which is the mass of the $\rho$-meson. We show the potential calculated by the set D and those expected by the scalings Eqs. (32) – (34) in Fig. 17. The binding energy of the $\bar{K}N$ bound state is 21.0 MeV for the set D and the scattering energy is for 27 MeV for the p-wave. There is some deviation between the two, which is not, however, very large. To conclude this subsection, the potential obeys a simple scaling rule as long as the moment of inertia is unchanged.
FIG. 17: Potentials for the $\bar{K}N$ ($J^P = 1/2^-, I = 0$) channel from the bound state (left) and the $\bar{K}N$ ($J^P = 3/2^+, I = 0$) channel from a scattering state (right) for the parameter set D which are derived from the potentials for the set A by the scaling rules Eqs. (32) – (34). The scattering energies are -21.0 and 27 MeV for s- and p-waves, respectively.

V. SUMMARY

In this paper, we have discussed the kaon-nucleon scattering states and the kaon-nucleon potentials by a modified bound state approach in the Skyrme model [6]. In our approach, the potential contains terms of different orders of $1/N_c$ due to the change of projection and variation. In the limit $N_c \to \infty$, this violates the $1/N_c$ expansion series, but we think it reasonable for physical systems of weakly interacting kaon and nucleon, which may generate molecular like states.

First, we have investigated the phase shifts for the kaon-nucleon scattering with lower partial waves of the kaon. The obtained phase shifts indicate that the potential is attractive for the $\bar{K}N$ channel and repulsive for the $K\bar{N}$ one. Then, we have evaluated the scattering length for the $\bar{K}N$ scattering state but it is larger than experimental results and other theoretical calculations [20–24].

Second, to make further discussions for the potential, we have classified the $\bar{K}N$ potential into the seven components according to their natures with and without energy dependence. Then, we have fitted them by the Gaussian type functions. As a results, we have found that all the components can be fitted by the Gaussian type functions. Actually, we have verified that the binding energies of the $\bar{K}N$ bound state and the phase shifts derived from the fitted potential and those from the numerically obtained original ones agree well.

While fitting the potential, we have also investigated the scaling rules associated with the soliton profile function, when changing the model parameters $F_\pi$ and $e$. We have found that various components of the potential contain terms of different order of $1/N_c$, which obey different scaling rules, separately. However, by keeping the moment of inertia in the higher order terms unchanged when $F_\pi$ and $e$ are varied, these separate scaling rules reduce to a simple rule for each component.
For further studies, it would be necessary to take into account the finite mass effect of the pion. Furthermore, coupling of $\bar{K}N$ and $\pi\Sigma$ is important. Improvements by considering these aspects should be performed for more quantitative discussions of kaon-nucleon systems including $\Lambda(1405)$.

Appendix A: The equation of motion and interactions

In this appendix, we show the explicit expressions of various terms in the equation of motion Eq. (14),

$$- \frac{1}{r^2} \frac{d}{dr} \left( r^2 h(r) \frac{dk^\alpha_l(r)}{dr} \right) - E^2 f(r) k^\alpha_l(r) + \left( m^2_K + V(r) \right) k^\alpha_l(r) = 0,$$

where

$$h(r) = 1 + \frac{2}{(eF)^2} \frac{1}{r^2} \sin^2 F,$$

$$f(r) = 1 + \frac{1}{(eF)^2} \left( \frac{2}{r^2} \sin^2 F + F'^2 \right),$$

$$V(r) = V_0^c(r) + V_\tau^c(r) I_{KN} + V_0^{LS} r J_{KN} + V_\tau^{LS} r J_{KN} I_{KN}. $$

In Eq. (A1), we define $I_{KN}$ and $J_{KN}$ as follows

$$I_{KN} = I^K \cdot I^N, \quad J_{KN} = L^K \cdot J^N, $$

where the nucleon spin and isospin operators, $J^N$ and $I^N$, are given by

$$J^N = i\Lambda tr \left[ \tau A^\dagger(t) A(t) \right], \quad I^N = i\Lambda tr \left[ \tau A^\dagger(t) A^\dagger(t) \right].$$

In Eq. (A6), $A(t)$ is the time derivative of an isospin rotation matrix, $A(t)$, $\tau$ are the $2 \times 2$ Pauli matrices, and $\Lambda$ is the soliton moment of inertia given by

$$\Lambda = \frac{2\pi}{3} F^2 \int dr \ r^2 \sin^2 F \left[ 1 + \frac{4}{(eF)^2} \left( F'^2 + \frac{\sin^2 F}{r^2} \right) \right].$$

The isospin and angular momentum operators of the kaon, $I^K$ and $L^K$, are given by

$$I^K = \frac{\tau}{2}, \quad L^K = r \times p^K, $$

$$J^N = i\Lambda tr \left[ \tau A^\dagger(t) A(t) \right], \quad I^N = i\Lambda tr \left[ \tau A^\dagger(t) A^\dagger(t) \right].$$

In Eq. (A6), $A(t)$ is the time derivative of an isospin rotation matrix, $A(t)$, $\tau$ are the $2 \times 2$ Pauli matrices, and $\Lambda$ is the soliton moment of inertia given by

$$\Lambda = \frac{2\pi}{3} F^2 \int dr \ r^2 \sin^2 F \left[ 1 + \frac{4}{(eF)^2} \left( F'^2 + \frac{\sin^2 F}{r^2} \right) \right].$$

The isospin and angular momentum operators of the kaon, $I^K$ and $L^K$, are given by

$$I^K = \frac{\tau}{2}, \quad L^K = r \times p^K, $$

$$J^N = i\Lambda tr \left[ \tau A^\dagger(t) A(t) \right], \quad I^N = i\Lambda tr \left[ \tau A^\dagger(t) A^\dagger(t) \right].$$
where $p^K$ is the momentum of the kaon.

Finally, the explicit forms of each term in the interaction, $V(r)$, are given by the following equations.

$$V_0^c(r) = -\frac{1}{4} \left( \frac{2\sin^2 F}{r^2} + (F')^2 \right) + 2\frac{s^4}{r^2} + \left[ 1 + \frac{1}{(eF)^2} \left( F'^2 + \frac{\sin^2 F}{r^2} \right) \right] \frac{l(l+1)}{r^2}$$

$$-\frac{1}{(eF)^2} \left[ 2\frac{\sin^2 F}{r^2} \left( \frac{\sin^2 F}{r^2} + 2(F')^2 \right) - 2\frac{s^4}{r^2} \left( F'^2 + \frac{\sin^2 F}{r^2} \right) \right]$$

$$+ \frac{1}{(eF)^2} \frac{6}{r^2} \left[ \frac{s^4 \sin^2 F}{r^2} + \frac{d}{dr} \left( s^2 \sin F' \right) \right]$$

$$+ \frac{2E}{\Lambda} s^2 \left[ 1 + \frac{1}{(eF)^2} \left( F'^2 + \frac{5}{r^2} \sin^2 F \right) \right]$$

$$+ \frac{3}{(eF)^2} \frac{1}{r^2} \frac{d}{dr} \left[ r^2 \left( \frac{EF' \sin F}{\Lambda} \right) \right] \pm \frac{3}{\pi^2 F^2 \Lambda} \frac{\sin^2 F}{r^2} F' \left( E - \frac{s^2}{\Lambda} \right), \quad (A9)$$

$$V_\tau^c(r) = \frac{8E}{3\Lambda} s^2 \left[ 1 + \frac{1}{(eF)^2} \left( F'^2 + \frac{4}{r^2} \sin^2 F \right) \right] + \frac{4}{(eF)^2} \frac{1}{r^2} \frac{d}{dr} \left[ r^2 \left( \frac{EF' \sin F}{\Lambda} \right) \right], \quad (A10)$$

$$V_0^{LS}(r) = \frac{1}{(eF)^2} \frac{2E \sin^2 F}{\Lambda r^2} \pm \frac{3}{F^2 \pi^2 \Lambda} \frac{\sin^2 F}{r^2} F', \quad (A11)$$

and

$$V_\tau^{LS}(r) = -\left[ 1 + \frac{1}{(eF)^2} \left( F'^2 + \frac{4}{r^2} \sin^2 F \right) \right] \frac{16s^2}{3r^2} - \frac{1}{(eF)^2} \frac{8}{r^2} \frac{d}{dr} \left( \sin F' \right), \quad (A12)$$

where

$$s = \sin \left( F(r)/2 \right), \quad (A13)$$

and

$$F' = dF(r)/dr. \quad (A14)$$

The last terms of Eq. (A9) and Eq. (A11) are derived from the Wess-Zumino term, which is attractive for the $\bar{K}N$ potential and repulsive for the $KN$ potential.

**Appendix B: Fitting parameters**

In this appendix, we show the fitting parameters discussed in Sec. [IVB].

[28] In our previous paper [6], we reported that there was no bound state for the $I=1$ channel with the parameter set B. After improving our numerical calculations, however, we have found a very shallow bound state with binding energy 0.2 MeV.
