ABSTRACT

The transverse energy $E_T$ in PbPb collisions at 2.76 TeV nucleon-nucleon center-of-mass energy $\sqrt{s_{NN}}$ has been measured over a broad range of pseudorapidity $\eta$ and collision centrality using the CMS detector at the LHC. The transverse energy density per unit pseudorapidity $d(E_T)/d(\eta)$ increases faster with collision energy than the charged particle multiplicity. This implies that the mean energy per particle is increasing with collision energy. At all pseudorapidities the transverse energy per participating nucleon increases with the centrality of the collision. The ratio of transverse energy per unit pseudorapidity in peripheral to central collisions varies significantly as the pseudorapidity increases from $\eta = 0$ to $|\eta| = 5.0$. For the most central collisions the energy density per unit volume is estimated to be about 15 GeV/fm$^3$ at a time of 1 fm/c after the collision. This is about 100 times larger than normal nuclear matter density and a factor of 2.8 times higher than the energy density reported at $\sqrt{s_{NN}} = 200$ GeV at RHIC.

Measurement of the Pseudorapidity and Centrality Dependence of the Transverse Energy Density in Pb-Pb Collisions at $\sqrt{s_{NN}} = 2.76$ TeV

S. Chatrchyan et al.*
(CMS Collaboration)
(Received 12 May 2012; published 8 October 2012)

The transverse energy ($E_T$) in Pb-Pb collisions at 2.76 TeV nucleon-nucleon center-of-mass energy ($\sqrt{s_{NN}}$) has been measured over a broad range of pseudorapidity ($\eta$) and collision centrality by using the CMS detector at the LHC. The transverse energy density per unit pseudorapidity ($dE_T/d\eta$) increases faster with collision energy than the charged particle multiplicity. This implies that the mean energy per particle is increasing with collision energy. At all pseudorapidities, the transverse energy per participating nucleon increases with the centrality of the collision. The ratio of transverse energy per unit pseudorapidity in peripheral to central collisions varies significantly as the pseudorapidity increases from $\eta = 0$ to $|\eta| = 5.0$. For the 5% most central collisions, the energy density per unit volume is estimated to be about 14 GeV/fm$^3$ at a time of 1 fm/c after the collision. This is about 100 times larger than normal nuclear matter density and a factor of 2.6 times higher than the energy density reported at $\sqrt{s_{NN}} = 200$ GeV at the Relativistic Heavy Ion Collider.

DOI: 10.1103/PhysRevLett.109.152303 PACS numbers: 25.75.Gz

The goal of relativistic heavy-ion collisions is to study the behavior of quarks and gluons under extreme conditions of pressure, density, and temperature, such as those that existed shortly after the big bang. Similar conditions can be reproduced in the laboratory by colliding heavy nuclei at the highest possible energies. Experiments at the Relativistic Heavy Ion Collider (RHIC) have shown that at a nucleon-nucleon center-of-mass energy of $\sqrt{s_{NN}} = 200$ GeV a strongly interacting medium is produced. This system behaves as an almost perfect quantum fluid [1–4]. There are also indications from the RHIC experiments that at these energies the initial state of the colliding nuclei may be a color glass condensate [1,5,6]. The presence of such a state may affect the spatial distribution of partons within the nucleus, particularly at high pseudorapidity [7,8]. Measuring the distribution of transverse energy over a wide pseudorapidity range sheds light also on the longitudinal expansion of the system. In 2010, the Large Hadron Collider (LHC) accelerated heavy ions to energies 14 times higher than RHIC in order to produce matter at energy densities never achieved before. One of the basic measurements in this new regime is that of the energy distribution of all the produced particles, which is connected to the initial energy and entropy densities of the produced matter. At lower energies, the measured rapidity distributions of particles are generally well described by Gaussians. The widths of these distributions are consistent with the predictions of Landau hydrodynamics, i.e., $\sigma_y = \sqrt{\ln \gamma}$, where $\gamma$ is the Lorentz factor of the colliding beams [9–13]. The rapidity variable $y = \tanh^{-1}(v_z/c)$, where $v_z$ is the velocity of the particle along the beam direction $z$, provides a way to describe the longitudinal distribution of matter created in these collisions. Calorimeters measure only the energy deposited at various angles, and therefore the data are presented in terms of the distribution of energy in pseudorapidity, $\eta$. Pseudorapidity is defined as $\eta \equiv -\ln[\tan(\theta/2)]$, with $\theta$ the polar angle with respect to the $z$ axis. When the momentum of a particle is larger than its mass, its $\eta \approx y$.

The Compact Muon Solenoid (CMS) experiment is a general-purpose detector designed to study hadron collisions at the TeV scale [14]. In particular, it has almost hermetic calorimetry that is sensitive to the distribution of energy over nearly the complete angular range. The transverse energy is defined by $E_T = \sum_i E_i \sin \theta_i$, where $E_i$ is the energy seen by the calorimeter for the $i$th particle, $\theta_i$ is the polar angle of particle $i$, and the sum is over all particles emitted into a fixed solid angle in an event. The quantity $dE_T/d\eta$ is an approximately Lorentz invariant measure of the energy distribution. The transverse energy is studied as a function of the geometry of the collision, i.e., the centrality, of the heavy-ion interaction. Finally, comparisons are made with lower-energy data and theoretical models.

The central feature of the CMS apparatus is a superconducting solenoid, of $6 \text{ m}$ internal diameter, providing a magnetic field of $3.8 \text{ T}$. Within the central field volume are the silicon pixel and strip trackers, lead-tungstate crystal electromagnetic calorimeter and the brass-scintillator hadron calorimeter. These calorimeters are physically divided into the barrel and end cap regions covering together the region of $|\eta| < 3.0$. The hadronic forward (HF)
calorimeters cover $|\eta|$ from 2.9 to 5.2. The HF calorimeters use quartz fibers embedded within a steel absorber. The CMS tracking system, located inside the calorimeter, consists of pixel and silicon-strip layers covering $|\eta| < 2.5$. A set of scintillator tiles, the beam scintillator counters, are mounted on the inner side of the HF calorimeters to trigger on heavy-ion collisions and reject beam-halo interactions. In addition, two zero degree calorimeters are used for systematic checks. For more details on CMS, see [14].

In 2010, CMS recorded Pb-Pb collision data corresponding to an integrated luminosity of 7.36 $\mu$b$^{-1}$, of which 0.31 $\mu$b$^{-1}$ were included in this analysis. This luminosity selection provided a data sample with negligible statistical uncertainties. Minimum bias inelastic Pb-Pb collisions were selected by requiring that either the HF or beam scintillator counters detected a signal on both sides of the interaction point. In the analysis at least two reconstructed tracks were required to form a vertex within $\pm 25$ cm of the nominal interaction point along the beam line and within a radius of 2 cm measured perpendicular to the beam relative to the average vertex position. Large-multiplicity beam-background events were removed by requiring the compatibility of the observed pixel-cluster lengths with the background events were removed by requiring the common vertex position. Large-multiplicity beam-background events were removed by requiring the compatibility of the observed pixel-cluster lengths with the background events were removed by requiring the common vertex position. Large-multiplicity beam-background events were removed by requiring the compatibility of the observed pixel-cluster lengths with the background events were removed by requiring the common vertex position.

Events were sorted into different centrality classes. The centrality of heavy-ion interactions is related to the number of participating nucleons and hence to the energy released in the collisions. In CMS, the centrality is defined as percentiles of the energy deposited in the HF. The most central (peripheral) event class, i.e., (0–2.5%)/(70–80)% in this analysis, has a large (small) number of participants and a large (small) energy deposit in HF. In order to estimate the mean number of participating nucleons $\langle N_{\text{part}} \rangle$ and its systematic uncertainty for each centrality class, a Glauber model of the nuclear collision was used [16–18].

The data were corrected for detector acceptance and inefficiencies using correction factors $C(|\eta|)$ estimated from the HYDJET 1.8 [19] Monte Carlo (MC) event generator coupled to a GEANT4 [20] CMS detector simulation. These correction factors were calculated as the ratio of MC predictions at the particle level and the detector level for each centrality class. The correction factor $C(|\eta|) = 1.6$ for $|\eta| < 2$ falls to $\approx 1.1$ by $|\eta| = 4$ and then rises to 2 at $|\eta| = 5$. The nonlinearity of the calorimeter response and the effect of the magnetic field cause the $C(|\eta|)$ to depend upon the $p_T$ spectra, the ratio of charged to neutral particles, and the mixture of mesons and baryons. The value of $C(|\eta|)$ increases if the assumed spectra shift to lower $p_T$ or if the ratio of charged to neutral particles is larger. To estimate the systematic uncertainties in $C(|\eta|)$, two tunes of HYDJET (1.6 and 1.8) were used. HYDJET 1.8, $\langle p_T \rangle_{ch} = 0.66$ GeV/c, was tuned to LHC spectra and particle yields as measured by the ALICE Collaboration [21] and successfully tested against a wide range of RHIC data. HYDJET 1.6, $\langle p_T \rangle_{ch} = 0.57$ GeV/c, was tuned only to RHIC data [19]. At central pseudorapidity, the fraction of $E_T$ carried by charged pions, kaons, protons, and antiprotons is 0.60 for HYDJET 1.6 and 0.62 for HYDJET 1.8. The results were cross-checked by using data taken with no magnetic field, and in addition, for $B = 3.8$ T, data from tracks with $p_T > 900$ MeV/c were combined with energy clusters in the calorimeters to identify different types of particles and measure their energy. Since muons and neutrinos carry a negligible fraction of the total transverse energy and deposit almost no signal in the calorimeters, they are not considered in this analysis and no correction factors are applied to account for them. The corrected transverse energy for $N$ analyzed events is obtained as

$$dE_T/d\eta (|\eta|) = C(|\eta|) \sum_j E_{T,j}(|\eta|) / N \times (2 \times \Delta \eta),$$

where the sum over $j$ covers all calorimeters located within the $\eta$ range $\Delta \eta$ and $E_{T,j}$ is the transverse energy measured in a particular cell $j$. Note that for this summation no threshold is applied to the individual calorimeters. Several sources of systematic uncertainties were studied, and their effects are summarized in Table I and described below. Energy scale: All of the calorimeters were initially calibrated with test beam data and radioactive sources. For the barrel and inner end cap calorimeters, these calibrations were refined by using isolated charged hadrons whose momentum was reconstructed in the tracker. For the HF calorimeter the energy scale was cross-checked by reconstructing $Z \rightarrow e^+ e^-$ in $pp$ collisions where either the positron or the electron was recorded in the electromagnetic calorimeter and tracker. Symmetry about $\eta$: For Pb-Pb collisions the corrected $dE_T/d\eta$ should be symmetric about $\eta = 0$. The values of $\langle N_{\text{part}} \rangle$

dE_T/d\eta for positive and negative \eta were found to differ by at most 0.5%. This close agreement implies that one can use the average of the two results as a best estimate of dE_T/d\eta. Vertex distribution: The \eta distribution of the vertices is Gaussian with \sigma_\eta = 6.1 cm. To test the sensitivity of E_T to the position of the interaction vertex along the beam line, \eta, the data set was divided into two samples with |\eta| < 10 cm and 10 cm < |\eta| < 25 cm, respectively. The E_T distributions of the two samples differ by less than 2%. Autocorrelations: Since HF is used both to calculate centrality and to measure E_T for each centrality class, there is an autocorrelation in the measurement. This effect was estimated to be less than 1.5% by using a combination of the zero degree calorimeters and pixel detectors to measure centrality. Calorimeter noise: The GEANT4 simulation of the calorimeters included electronic noise. This noise was measured by studying a sample of events where the trigger required only the presence of clockwise and anticlockwise bunches of lead ions simultaneously in CMS. The simulation of the noise was checked by comparing the data to the simulated signal from a GEANT4 simulation of the most peripheral events in the data set. Any discrepancy in the simulation of the noise corresponds to a corrected average E_T per event of less than 5.8 GeV for |\eta| \leq 2.65 and 1.2 GeV for 2.65 < |\eta| \leq 5.2. This is significant only compared to the signal for \langle N_{part} \rangle \leq 30. The HF MC description takes into account different ways of describing the dead areas of the HF detector. Centrality determination: The systematic uncertainty related to the centrality determination is applied only to the results that are normalized by \langle N_{part} \rangle.

Figure 1 shows the |\eta| dependence of the transverse energy density for four selected ranges of centrality. For the most central collisions (\langle N_{part} \rangle = 394), dE_T/d\eta reaches 2.1 TeV at |\eta| = 0. This is much larger than the value of 0.61 TeV measured at \sqrt{s_{NN}} = 200 GeV [22]. At lower center-of-mass energies, the pion multiplicity distributions are reasonably well described by Gaussians in rapidity with widths that are consistent with Landau-Carruthers hydrodynamics [23,24]. Since the mean p_T of all particle species depends only weakly on rapidity, this implies that dE_T/dy is roughly Gaussian in rapidity at \sqrt{s_{NN}} = 200 GeV. Recently, Wong has improved the formulation of Landau hydrodynamics [25]. This new formulation gives a better description of the 200 GeV RHIC data. At \sqrt{s_{NN}} = 2.76 TeV and for |\eta| < 5.2, the dE_T/d\eta is consistent with a Gaussian (black solid line) with \sigma_\eta = 3.4 \pm 0.1 for the most central collisions. The Gaussian and Landau curves in Fig. 1 are normalized to the CMS data at |\eta| = 0. Both the Landau-Carruthers (blue dashed line) and Landau-Wong (green dotted line) formulations have distributions that are narrower than the data. Therefore, the longitudinal expansion of the system is stronger than that predicted from either model. HYDJET 1.8, shown by the purple dashed line, has been tuned to LHC data in the small |\eta| region. It gives a good description of dE_T/d\eta at small |\eta| but overestimates the data at large |\eta| for central collisions. The AMPT (a multiphase transport) model [26,27] (orange dashed line) overestimates dE_T/d\eta for central collisions but is in rough agreement with the shape of dE_T/d\eta. Integrating (dE_T/d\eta)/\langle N_{part} \rangle/2 over \eta between −5.2 and 5.2 gives a total measured E_T per participant pair of 80 ± 4 GeV for the most central events. This serves as a lower limit for the total transverse energy per nucleon pair. Extrapolating to the full phase space gives a total transverse energy per pair of participating nucleons of 91 ± 5 GeV for the most central events. It is clear from Fig. 1 that the magnitude of dE_T/d\eta increases rapidly with the number of nucleons participating in the collision.

Figure 2 shows the evolution of (dE_T/d\eta)/\langle N_{part} \rangle/2 with \langle N_{part} \rangle for several |\eta| regions. At all |\eta| values (dE_T/d\eta)/\langle N_{part} \rangle/2 increases with \langle N_{part} \rangle. This figure shows that the \langle N_{part} \rangle dependence of transverse energy density changes as a function of pseudorapidity. This effect can be quantified by comparing peripheral (60–70)% (\langle N_{part} \rangle = 30) to central (0–2.5)% collisions (\langle N_{part} \rangle = 394) at various pseudorapidities. The ratio of peripheral to central (dE_T/\eta)/\langle N_{part} \rangle/2 changes from 54 ± 2% at \eta = 0 to 68 ± 2% at |\eta| = 5.0. The PHENIX Collaboration at RHIC has studied transverse energy density in Au-Au collisions for |\eta| < 0.35 over a wide range of centralities and for \sqrt{s_{NN}} from 19.6 to 200 GeV [22]. At \sqrt{s_{NN}} = 19.6 GeV, (dE_T/d\eta)/\langle N_{part} \rangle/2 at \eta = 0 increases by a factor of 1.25 ± 0.17 as \langle N_{part} \rangle increases.
At a very forward pseudorapidity of \(\eta = 0\), the energy density of the produced system at LHC is larger than that measured for \(\sqrt{s_{NN}} = 2.76\) TeV at several values of \(|\eta|\). The bands show the total systematic uncertainties. The statistical uncertainties are negligible. For \(\eta = 0\), lower-energy PHENIX data and results from the HYDJET 1.8 model are also shown.

Figure 3 shows the energy dependence of \((dE_t/d\eta)/\langle N_{\text{part}}/2\rangle\) for central collisions at \(\eta = 0\). For the top 5% most central events, \((dE_t/d\eta)/\langle N_{\text{part}}/2\rangle\) reaches \(10.5 \pm 0.5\) GeV at \(\sqrt{s_{NN}} = 2.76\) TeV. The \(E_t\) rises more quickly with the center-of-mass energy than the logarithmic dependence used to describe data up to \(\sqrt{s_{NN}} = 200\) GeV. For energies between 8.7 GeV and \(2.76\) TeV, \(dE_t/d\eta\) at \(\eta = 0\) can be reproduced by a power-law dependence of the type \(s_{NN}^0\) with \(n = 0.2\). A similar effect has been seen in the measurement of the \(\frac{s_{NN}}{s_{NN}}\) evolution of the charged particle multiplicity [18,28]. The \((dE_t/d\eta)/\langle N_{\text{part}}/2\rangle\) increases by a factor of \(3.07 \pm 0.24\) from \(\sqrt{s_{NN}} = 200\) GeV to \(2.76\) TeV. This is to be compared to a factor of \(2.17 \pm 0.15\) for the pseudorapidity density, \((dN_{ch}/d\eta)/\langle N_{\text{part}}/2\rangle\) [18,21,22]. For the 5% most central collisions, CMS has measured \(dN_{ch}/d\eta = 2007 \pm 100\) GeV and \(dN_{ch}/d\eta = 1612 \pm 55\) [18]. Dividing the measured transverse energy by the observed charged particle multiplicity for the same centrality gives a transverse energy per charged particle of \(1.25 \pm 0.08\) GeV at \(\sqrt{s_{NN}} = 2.76\) TeV. This compares to \(0.88 \pm 0.07\) GeV at \(\sqrt{s_{NN}} = 200\) GeV [22].

The sum of the transverse energies of all particles produced in the event depends upon both the entropy and the temperature of the system. Using geometrical considerations, Bjorken [29] suggested that the energy density per unit volume in nuclear collisions could be estimated from the energy density per unit rapidity. A commonly used estimate of energy density is given by [22]

\[
\epsilon = \frac{1}{Ac\tau_0} J(y, \eta) \frac{dE_t}{d\eta},
\]

where \(A\) is the overlap area of the two nuclei and \(\tau_0\) is the formation time of the produced system. The Jacobian \(J(y, \eta)\) depends on the momentum distributions of the produced particles. In the limit that the rest masses of the particles are much smaller than their momenta, \(J(y, \eta) = 1\). The average Jacobian was calculated by using HYDJET 1.8 for \(|\eta| < 0.35\). For central collisions at \(\sqrt{s_{NN}} = 2.76\) TeV, \(J(y, \eta) = 1.09\). This compares to 1.25 at \(\sqrt{s_{NN}} = 200\) GeV [22]. For the top 5% most central collisions, this formula gives \(\epsilon = 14\) GeV/fm\(^3\) at a time \(\tau_0 = 1\) fm/c and for a transverse surface of \(A = \pi \times (7\) fm\(^2\)^2 [22]. This is a factor of 2.6 times larger than the energy density calculated at \(\sqrt{s_{NN}} = 200\) GeV [22].

In summary, for the most central Pb-Pb collisions at \(\sqrt{s_{NN}} = 2.76\) TeV, the maximum of the transverse energy distribution has been found to be 2.1 TeV at \(\eta = 0\). Even at a very forward pseudorapidity of \(|\eta| = 5.0\), \(dE_t/d\eta\) and hence the energy density of the produced system at the LHC is larger than that measured for \(\eta = 0\) at RHIC.
At 2.76 TeV, the shape of \(dE_T/d\eta\) is consistent with a Gaussian function of width \(\sigma_\eta = 3.4 \pm 0.1\) for central collisions. This distribution is wider than the prediction of Landau hydrodynamics but narrower than that given by the HYDJET 1.8 simulation. The \(\langle dE_T/d\eta\rangle/(\langle N_{\text{part}}\rangle/2)\) increases with \(\langle N_{\text{part}}\rangle\) at all pseudorapidities. The ratio of transverse energy in peripheral compared to central collisions increases by a factor of \(1.26 \pm 0.06\) from \(\eta = 0\) to \(|\eta| = 5\). The transverse energy density at \(\eta = 0\) grows more rapidly with the center-of-mass energy than the logarithmic scaling with \(\sqrt{s_{NN}}\) that describes lower-energy data. It also grows faster with energy than the multiplicity, implying a significant increase of the mean transverse energy per particle compared to lower-energy data.

We congratulate our colleagues in the CERN accelerator departments for the excellent performance of the LHC machine. aDeceased.
bAlso at Vienna University of Technology, Vienna, Austria.
cAlso at National Institute of Chemical Physics and Biophysics, Tallinn, Estonia.
dAlso at Universidade Federal do ABC, Santo Andre, Brazil.
eAlso at California Institute of Technology, Pasadena, CA, USA.
fAlso at CERN, European Organization for Nuclear Research, Geneva, Switzerland.
gAlso at Laboratoire Leprince-Ringuet, Ecole Polytechnique, IN2P3-CNRS, Palaiseau, France.
hAlso at Suez Canal University, Suez, Egypt.
iAlso at Zewail City of Science and Technology, Zewail, Egypt.
jAlso at Cairo University, Cairo, Egypt.
kAlso at Fayoum University, El-Fayoum, Egypt.
lAlso at Ain Shams University, Cairo, Egypt.
mAlso at British University, Cairo, Egypt.
nAlso at National Centre for Nuclear Research, Swierk, Poland.
oAlso at Université de Haute-Alsace, Mulhouse, France.
pAlso at Joint Institute for Nuclear Research, Dubna, Russia.
qAlso at Moscow State University, Moscow, Russia.
rAlso at Brandenburg University of Technology, Cottbus, Germany.
sAlso at Institute of Nuclear Research ATOMKI, Debrecen, Hungary.
tAlso at Eötvös Loránd University, Budapest, Hungary.
uAlso at Tata Institute of Fundamental Research - HECR, Mumbai, India.
vAlso at University of Visva-Bharati, Santiniketan, India.
wAlso at Sharif University of Technology, Tehran, Iran.
xAlso at Isfahan University of Technology, Isfahan, Iran.
yAlso at Plasma Physics Research Center, Science and Research Branch, Islamic Azad University, Tehran, Iran.
zAlso at Facoltà Ingegneria Università di Roma, Roma, Italy.
aaAlso at Università della Basilicata, Potenza, Italy.
bbAlso at Università degli Studi Guglielmo Marconi, Roma, Italy.
cAlso at Università degli Studi di Siena, Siena, Italy.
dAlso at University of Bucharest, Faculty of Physics, Bucuresti-Magurele, Romania.
eAlso at Faculty of Physics of University of Belgrade, Belgrade, Serbia.
fAlso at University of California, Los Angeles, Los Angeles, CA, USA.
g#Also at Scuola Normale e Sezione dell’ INFN, Pisa, Italy.
hAlso at INFN Sezione di Roma, Università di Roma, Roma, Italy.
iAlso at University of Athens, Athens, Greece.
jAlso at Rutherford Appleton Laboratory, Didcot, United Kingdom.
kAlso at The University of Kansas, Lawrence, KS, USA.
lAlso at Paul Scherrer Institut, Villigen, Switzerland.
mAlso at Institute for Theoretical and Experimental Physics, Moscow, Russia.
nAlso at Gaziosmanpasa University, Tokat, Turkey.
oAlso at Adiyaman University, Adiyaman, Turkey.
pAlso at Izmir Institute of Technology, Izmir, Turkey.
qAlso at The University of Iowa, Iowa City, IA, USA.
rAlso at Mersin University, Mersin, Turkey.
sAlso at Ozyegin University, Istanbul, Turkey.
tAlso at Kafkas University, Kars, Turkey.
uAlso at Suleyman Demirel University, Isparta, Turkey.
vAlso at Ege University, Izmir, Turkey.
wAlso at School of Physics and Astronomy, University of Southampton, Southampton, United Kingdom.
xAlso at INFN Sezione di Pisa, Università di Pisa, Pisa, Italy.
yAlso at University of Sydney, Sydney, Australia.
zz Also at Utah Valley University, Orem, UT, USA.

aaa Also at Institute for Nuclear Research, Moscow, Russia.

bbb Also at University of Belgrade, Faculty of Physics and Vinca Institute of Nuclear Sciences, Belgrade, Serbia.

ccc Also at Argonne National Laboratory, Argonne, IL, USA.

ddd Also at Erzincan University, Erzincan, Turkey.

eee Also at KFKI Research Institute for Particle and Nuclear Physics, Budapest, Hungary.

fff Also at Kyungpook National University, Daegu, Korea.
