Abstract

Objectives: Analyse the effect of the Mahatma Gandhi National Rural Employment Guarantee Act (MGNREGA), a wage-for-employment policy of the Indian Government, on infant malnutrition and delineate the pathways through which MGNREGA affects infant malnutrition. Hypothesis: MGNREGA could reduce infant malnutrition through positive effects on household food security and infant feeding.

Method: Mixed methods using cross-sectional study and focus group discussions conducted in Dungarpur district, Rajasthan, India. Participants: Infants aged 1 to <12 months and their mothers/caregivers. Final sample 528 households with 1,056 participants. Response rate 89.6%. Selected households were divided into MGNREGA-households and non-MGNREGA-households based on participation in MGNREGA between August-2010 and September-2011. Outcomes: Infant malnutrition measured using anthropometric indicators - underweight, stunting, and wasting (WHO criteria).

Results: We included 528 households with 1,056 participants. Out of 528, 281 households took part in MGNREGA between August’10, and September’11. Prevalence of wasting was 39%, stunting 24%, and underweight 50%. Households participating in MGNREGA were less likely to have wasted infants (OR 0.57, 95% CI 0.37–0.89, p = 0.014) and less likely to have underweight infants (OR 0.48, 95% CI 0.30–0.76, p = 0.002) than non-participating households. Stunting did not differ significantly between groups. We did 11 focus group discussions with 62 mothers. Although MGNREGA reduced starvation, it did not provide the desired benefits because of lower than standard wages and delayed payments. Results from path analysis did not support existence of an effect through household food security and infant feeding, but suggested a pathway of effect through low birth-weight.

Conclusion: Participation in MGNREGA was associated with reduced infant malnutrition possibly mediated indirectly via improved birth-weight rather than by improved infant feeding. Addressing factors such as lack of mothers’ knowledge and inappropriate feeding practices, over and above the social and economic policies, is key in efforts to reduce infant malnutrition.

Introduction

In 2005–06, more than 40% of children in India were malnourished [1]. Malnutrition increases the risk of morbidity [2] and mortality among infants [3]. Macroeconomic and social policies can influence household income and poverty status which in turn function as social determinants of infant malnutrition [4–6]. The Mahatma Gandhi National Rural Employment Guarantee Act (MGNREGA) of Government of India targets deprivation and food insecurity in rural households [7,8]. It is suggested that MGNREGA may have a general positive effect on the nutrition and well-being of children [9]. A recent study demonstrated that MGNREGA was associated with improved height-for-age among children 3–6 years of age [8]. However, the particular effect of MGNREGA on infant malnutrition is not known. We hypothesised that MGNREGA could reduce infant malnutrition through its positive effects on household food security and infant feeding. The aim of this study was to analyse the effect of MGNREGA on infant malnutrition and to delineate the pathways through which MGNREGA affects infant malnutrition. We found a positive effect of MGNREGA on infant nutrition mainly mediated through birth-weight.
Methods

Ethics Statement
Ethics approvals for the study were obtained from the Directorate of Medical, Health and Family Welfare Services, Government of Rajasthan, Jaipur and the University of Oxford Tropical Research Ethics Committee (OXTREC); OXTREC Reference: 43-11. Participant information sheet and consent form in local languages were used to elicit written informed consent from all participants before implementing the survey questionnaire. Written informed consent was taken from the mothers of infants before measuring the weight and length of infants. Written informed consent was also taken from all participants before the focus group discussions.

Study Design
MGNREGA is a wage-for-employment policy that “provides 100 days of guaranteed wage-employment to rural households whose adult members volunteer to do unskilled manual work” [10]. We conducted a literature review which suggested that MGNREGA as a source of income in the participating households could lead to food security, which would have a positive effect on infant feeding and thus, reduce their risk of malnutrition [10–12]. However, factors such as infant feeding practices and mothers’ knowledge about infant care and feeding could influence this pathway of effect [13–15]. Based on existing literature, a conceptual framework was developed to link MGNREGA and infant malnutrition (fig. 1), which guided the study design, data collection and analyses. We employed a mixed design i.e. a quantitative cross-sectional study and qualitative focus group discussions to analyse the effect and the mechanisms of effect of MGNREGA on infant malnutrition.

Cross-sectional Study
MGNREGA is currently implemented in all districts in India, thus using an intervention trial to analyse its effect on infant malnutrition was not possible. The study was conducted in the Dungarpur district in the Indian state of Rajasthan where MGNREGA has been implemented since September, 2006. The degree of poverty and unemployment in the district alongside a high prevalence of malnutrition among children [16] makes it an appropriate setting for examining the potential benefits of MGNREGA.

The target sample size of 540 households for the cross-sectional study was calculated assuming a two-sided, two-sample comparison of proportions. The assumed baseline prevalence of being malnourished was based on the reported prevalence of the anthropometric indicators - underweight 41.7%, wasting 19.2% and stunting 53.4% in children under 5 years of age in Dungarpur district [17]. The minimum expected effect size was 13%, an effect demonstrated in the study by Uppal in Andhra Pradesh, India that demonstrated in the study by Uppal in Andhra Pradesh, India that showed an increase in the height-for-age of children (5–6 years) of 12.5% in a sample of 615 children in comparison to a control group [8]. Equal sample size in each group (employed MGNREGA households and non-MGNREGA households) was assumed for the three traditional anthropometric indicators of malnutrition – wasting, stunting and underweight were used as outcome variables. Wasting (low weight-for-height/length) is an indicator of “current nutritional status” and is an established measure of acute malnutrition [19–21]. Stunting is a measure of linear growth (low height/length-for-age) and reflects prolonged growth faltering [21], and underweight (low weight-for-age) is a composite indicator of wasting and stunting [21]. The recumbent length and weight of infants were measured using a portable infantometer (Seca 417, seca deutschland, Hamburg, Deutschland) and an electronic digital weighing scale (Seca 394, seca deutschland, Hamburg, Deutschland), respectively. The measurement methods were based on standard guidelines provided in the manual of the World Health Organisation’s (WHO) Multicentre Growth Reference Study [22]. The z-scores of weight-for-age, length-for-age and weight-for-length were calculated using the WHO 2007 STATA macro package (Statacorp, Texas, USA). Using a cut-off of less than minus two standard deviation (≤−2SD) compared with the standard WHO-Multicentre Growth Reference Study population [23], the infants were categorised as underweight, stunted or wasted.

Household food security was measured using the standard Food and Nutrition Technical Assistance–2 (FANTA-2) household food insecurity indicator - Household Dietary Diversity Score [24]. ‘Adequate infant feeding practices’ was a composite variable of two indicators for assessing infant and young child feeding practices [25]. Definitions and descriptions of the 36 independent variables identified from literature as determinants of infant malnutrition and included in this study are provided in table 1.

Focus Group Discussions
Focus groups were used to generate themes and interactions through group discussion with the mothers of infants to explore the proposed mechanisms of effect of MGNREGA on infant malnutrition. A purposive sampling method based on mothers’ willingness to participate was used to recruit participants for eleven focus group discussions (two in each of the five administrative blocks and one pilot study). Participants comprised of 62 mothers of infants who were a sub-set of the randomly selected participants for the cross-sectional study (a nested sampling approach). The focus group discussions were conducted by MN with the help of a trained nurse using a semi-structured topic guide. The discussions were recorded, transcribed non-verbatim and translated into English. The transcripts were managed using the QSR International’s NVivo9 software and analysed using set and emergent themes.
Statistical Analyses

Descriptive analyses of all variables were conducted. Univariate logistic regression analyses were done for each of the three binary anthropometric outcomes – underweight, wasting and stunting to estimate the crude odds ratios. Since participation in MGNREGA was not randomised, exploratory logistic regression analysis was also used to identify the factors that influenced households’ participation in MGNREGA. These factors along with other known confounders were then entered into the multivariable logistic regression models to estimate the adjusted effects of households’ participation in MGNREGA on the anthropometric indicators of malnutrition. Tests for interaction were conducted to identify the factors that could modify the effect of MGNREGA on the outcome variables. To account for data dependency and within-cluster correlations, robust standard errors (Huber-White sandwich estimator) were reported.

Path analysis was performed to quantify the hypothetical pathways (shown in fig. 1) by fitting a set of regression equations under the assumption that the model is not affected by unmeasured confounding [26]. Weighted least square adjusted for mean and variance was used to estimate the parameters of the model [27]. Three model fit indices, Chi square($\chi^2$) test for model fit, Comparative Fit Index (CFI) and Root Mean Square Error of Approximation (RMSEA), each related to a specific aspect of the model were used to quantify the degree of correspondence between the hypothesized models and the data [28,29]. Indirect effects were computed by multiplying the relevant path coefficients. Statistical significance was considered at the 5% level and the analyses were performed using STATA version 11 (Statacorp, Texas, USA) and Mplus version 7.

Results

Of the total 528 households, 53% (95% Confidence Interval (CI) = 48.9–57.5; n = 281) participated in MGNREGA. The overall prevalence of underweight, stunting and wasting among the infants in the study households was 50.4% (95% CI = 46.0–54.7), 24.4% (95% CI = 20.8–28.3) and 39% (95% CI = 34.8–43.3), respectively. The characteristics of the study population are presented in table 2. More households employed through MGNREGA belonged to the lower socioeconomic status, were categorised as below poverty line households (as defined by the Planning Commission of India [30]) and were engaged in seasonal employment compared to non-MGNREGA households. Mean household density was higher in the MGNREGA-households and access to proper sanitation was lower compared to the non-MGNREGA households. Apart from these factors, the MGNREGA and non-MGNREGA households did not differ in other socio-demographic characteristics including household food security (table 3).

Further, the results of the exploratory logistic regression modelling conducted to elucidate systematic differences leading to MGNREGA participation and non-participation that may be brought about by factors such as socioeconomic status, belonging to below poverty line status, parents’ level of education, caste, household food security, households’ enrolment in Public Distribution system, primary occupation of the household and indicators for health seeking behaviour (treatment for diarrhoea, institutional delivery, household at least one sibling died and adequate vaccination) suggested that only households categorised as being below the poverty line were more likely to participate in the programme (OR = 1.98; 95% CI = 1.22–3.19; p = 0.006). Apart from this no other known factor was found to be significantly associated with participation in MGNREGA.

Effect on Malnutrition

The adjusted odds of infants being underweight and wasted in households participating in MGNREGA were respectively 52%
Table 1. Definition and construct of the independent variables.

| Sl. No | Variable name | Definition and construct |
|--------|---------------|-------------------------|
| **Proximal determinants/biological factors** | | |
| 1 | Diarrhoea | Defined as “three or more loose stools or any number of loose stools with blood in a twenty-four hour period” [35]. |
| 2 | Upper respiratory tract infection (URTI) | Defined on the basis of elicited history from mothers on the presence of the following symptoms – cough and fever with or without rapid breathing. |
| **Intermediate determinants/behavioural factors** | | |
| 3 | Adequate vaccination (age specific) | Vaccination history of the infants was matched with their age and based on the Universal Immunisation Programme schedule used in India, the infants were classified as having received adequate or inadequate (age specific) vaccination. |
| 4 | Early initiation of breast feeding | “Proportion of children born in the last 24 months who were put to the breast within one hour of birth” (WHO’s indicators for assessing infant and young child feeding practices [25]). |
| 5 | Adequate infant feeding practices | Composite variable of two indicators for assessing infant and young child feeding practices [25]: Infants’ under 6 months - Exclusive breastfeeding defined as “Proportion of infants 0–5 months of age who are fed exclusively with breast milk.” Infants’ ≥6 months - Minimum acceptable diet defined as “Proportion of children 6–23 months of age who receive a minimum acceptable diet (apart from breast milk).” The variable includes information on minimum meal frequency and minimum dietary diversity. |
| 6 | Cleanliness of water and food (Boiled water given to infants and Proper disposal of infant faeces) | Mothers were asked about the type of water given to infants and about the methods used to dispose infant stool. Based on the criteria for adequate method of faeces disposal provided by the WHO’s Core questions on drinking-water and sanitation for household surveys [36], the data was divided into adequate and inadequate. |
| 7 | Infant care (Duration of care by other carers, Adequate feeding during diarhoea and Oral Rehydration Salt to infants with diarhoea) | The continuous variable - total hours infant was cared for by someone other than the mother in the past week was categorised into “none”, 20 hours per week and >20 hours per week. The cut-off was based on the mean duration of care provided by the other carers = 19.5 (±0.63) hours per week in the sampled households. Infant feeding during episodes of diarhoea was classified as adequate and inadequate based on a score generated using the District Level Household Survey tool [37]. Mothers were also asked if Oral Rehydration Salt was given to the infants during diarhoea. |
| 8 | Health seeking behaviour (Treatment for diarrhoea/URTI, Mother had antenatal checkups, institutional delivery and Household at least one sibling died) | The infants were considered treated for diarrhoea/URTI if they were taken to a doctor/public or private hospital/village nurse. Mothers were asked whether they received any antenatal checkup during their pregnancy with the index child (child participating in the study). Place of delivery was enquired and classified as institutional or home delivery. The mothers were asked about the total number of children they have and if any child died. |
| **Intermediate determinants/socio-cultural factors** | | |
| 9 | Caste | Based on the social class system in India the households were divided into two groups – schedule caste and/or schedule tribe and other social class. Scheduled castes comprise of the social groups that has suffered the greatest burden of deprivation within the caste system and were regarded as untouchables [38]. Scheduled tribes include approximately 700 officially recognized social groups that have historically been geographically and socially isolated [39]. Other castes were those that did not belong to either of these groups and were presumably better off in their social status. |
| **Distal determinants/structural factors** | | |
| 10 | Access to safe drinking water and Proper sanitation | Sources of drinking water and sanitation/toilet facilities were categorised as adequate/proper and inadequate/improper based on the WHO’s Core questions on drinking-water and sanitation for household surveys [36]. |
| 11 | Crowding/household density | Defined as total number of members (physically living in the household) per room. |
| 12 | Socio-economic status | The Demographic and Health Survey [40] instrument was used to elicit information about the household amenities and assets including landownership and domestic animals which were then weighted using the factor loadings from a principal component analysis of the asset variables. The calculated scores of each asset variable were added to generate an asset index – a continuous variable which was then divided into quintiles. The lowest two quintiles were combined to construct four categories of the socioeconomic status variable. The method used is as suggested by the World Bank for calculating asset and wealth indices [41]. |
| 13 | Mothers’ level of education, Fathers’ level of education | Based on the reported history from the mother/caregiver, the education levels of mothers and fathers of infants were divided into – illiterate corresponding to no formal education, primary education if they completed primary school and secondary or higher education. Some mothers were taught to sign their names, but they did not know how to read or write, such mothers were categorised as illiterate. |
| 14 | Mother worked after delivery | Information was elicited with regards to whether the mothers of the index child worked to earn money after delivery and was classified as “not worked”, “worked in MGNREGA” and “employed in other jobs”. If the mothers worked in the family’s farm without pay, they were not considered as employed. |
| 15 | Primary occupation of household | Primary occupation of the household was elicited by enquiring about the profession of each adult member of the household. If any member had a regular job, the household was included under “regular occupation” and if all members were engaged in seasonal employment (agriculture/agriculture labours), the household was included under “seasonal occupation”. |
| 16 | Received food through the Public Distribution System | Whether the household received food from the Public Distribution System which facilitates the supply of food grains to the poor households at a subsidised price in India [42]. |
Mechanisms of Effect

Four themes emerged from the focus group discussions to help explain the quantitative findings relating MGNREGA to infant malnutrition. These included the effect of MGNREGA on household food security, impact of poverty on infant feeding, mothers’ knowledge of infant feeding and cultural factors affecting infant feeding.

**MGNREGA’s effect on household food security.** Agriculture is the main source of livelihood in the district of Dungarpur. The participants suggested that earnings from MGNREGA contributed towards preventing hunger and starvation when there was crop failure particularly among the poor.

> “If there is no Rojgar Guarantee [MGNREGA] then what do we eat? If we get some money [we] can buy food grains for the house and [we] can go on. What ripens in cultivation? What do we eat? There are no crops, so we have benefited from Rojgar [MGNREGA].” (M-13)

A participant employed through MGNREGA at the time of interview commented that if the programme was to be abolished, the poor people would be the losers because they do not have recourse to any other means of income. Although it was agreed that MGNREGA conferred some benefits in terms of preventing hunger during crop failure and meeting minor household expenses, the participants complained of low wages and delays in receiving payments. They did not trust the supervisors responsible for paying the wages to the workers, and commented that they siphoned off money and paid only a small portion of the daily wages to the workers. The participants perceived these as barriers to receiving the complete financial benefits from the programme.

> “Who gets 100 [INR]? The person responsible for paying us the wages takes away most of it. Last time I got 200 rupees for 11 days.” (M-19)

**Influence of poverty on infant feeding.** Poverty itself was a factor that negatively affected infant feeding. “Inability to afford” compromised the type of complementary foods given to the infants. These were mostly biscuits or a piece of dry roti (bread) made of either wheat or maize. Although the mothers were aware that these foods could harm the child, they could not afford to buy anything else. For example, a mother mentioned that her young daughter was unable to swallow dry bread and often vomited it out, so she had no option other than breastfeeding.

> “I started breastfeeding after 2 hours because I did not have enough milk. Milk comes only after 2 hours.” (M-40)

**Mothers’ knowledge of infant feeding.** Mothers’ knowledge of initiation of breastfeeding, exclusive breastfeeding and weaning appeared to be inadequate. There were several misconceptions such as breast milk is produced only after two hours of delivery of the child, and inappropriate practices such as giving water and animal milk (cow’s, goat’s, buffalo’s) with or without ghee (clarified butter) to infants <6 months.

> “I started breastfeeding after 2 hours because I did not have enough milk. Milk comes only after 2 hours.” (M-40)

---

### Table 1. Cont.

| Sl. No | Variable name | Definition and construct |
|--------|----------------|--------------------------|
| 17     | Below poverty line households | This was based on the availability of the below poverty line status card for the household. The Planning Commission of India defines “Below Poverty Line” households as households (average 5 family members) with per capita consumption expenditure of INR 672.8 on a monthly basis in rural areas and INR 859.6 in urban areas at prices prevailing in 2009–10 [30]. |
| 18     | Household food security | Measured as household dietary diversity score generated using the Food and Nutrition Technical Assistance-2 (FANTA-2) household food insecurity indicator - Household Dietary Diversity Score (HDDS) [24]. |
| 19     | Mothers participating in household decision making, Decision on spending mother’s earning, Decision on spending husband’s earning | The Demographic and Health Survey tool [40] for measuring women empowerment was used and three categorical variables each assessing the role of women in different types of household decision making were created. |

doi:10.1371/journal.pone.0075089.t001

(adjusted OR = 0.48; 95% CI = 0.30–0.76, p = 0.002) and 43% (OR = 0.57; 95% CI = 0.37–0.89; p = 0.014) lower compared with households that did not participate in MGNREGA after controlling for socioeconomic status, below poverty line, caste, duration of care by other carers, birth order and child’s age (table 4). There was no statistically significant difference in infant stunting between households participating in MGNREGA and those not (adjusted OR = 0.70; 95% CI = 0.46–1.05; p = 0.086).
Table 2. Description of the study population.

| Characteristics                                      | Number of households | *Proportion of households in % (95% Confidence Interval) |
|------------------------------------------------------|----------------------|----------------------------------------------------------|
| **Non-health policy: MGNREGA**                       |                      |                                                          |
| Employed through MGNREGA between Aug’10 and Sep’11  | 281                  | 53.2 (48.9, 57.5)                                        |
| **Outcome – Malnutrition**                           |                      |                                                          |
| Infant underweight ($<-2SD$ of WAZ)                  | 266                  | 50.4 (46, 54.7)                                          |
| Infant wasted ($<-2SD$ of WLZ)                       | 206                  | 39 (34.8, 43.3)                                          |
| Infant stunted ($<-2SD$ of LAZ)                      | 129                  | 24.4 (20.8, 28.3)                                        |
| **Proximal determinants/Biological factors**         |                      |                                                          |
| Infant having diarrhoea                              | 79                   | 15 (12, 18.3)                                            |
| Infant having Upper Respiratory Tract Infection (URTI)| 49                   | 9.3 (6.9, 12.1)                                          |
| **Intermediate determinants/Behavioural factors**    |                      |                                                          |
| Infant with adequate vaccination (age specific vaccination) | 207                 | 39.2 (35, 43.5)                                          |
| Adequate infant feeding                              | 122                  | 23.1 (19.6, 26.9)                                        |
| Cleanliness of water and food                        |                      |                                                          |
| Boiled water given to infants (Households infants given water, n = 380) | 7 | 1.8 (0.7, 3.8) |
| Baby utensils washed with hot water [Households utensils used, n = 393] | 254 | 64.6 (59.7, 69.4) |
| Yes                                                  | 139                  | 35.4 (30.6, 40.3)                                        |
| Proper disposal of infant faeces                     | 23                   | 4.4 (2.8, 6.5)                                           |
| **Health seeking for infants**                       |                      |                                                          |
| Treatment for diarrhoea/respiratory infections [n = 119] | 84                   | 70.6 (61.5, 78.6)                                        |
| At least one sibling died                            | 38                   | 7.2 (5.1, 9.7)                                           |
| Institutional delivery                               | 427                  | 80.9 (77.3, 84.1)                                        |
| **Infant care**                                      |                      |                                                          |
| Duration of care per week by other carers            |                      |                                                          |

Cultural factors affecting infant feeding. In addition to poverty, cultural practices appeared to inform mothers’ knowledge and influenced the infant feeding practices. Apart from initiation of breastfeeding and exclusive breastfeeding, the time of initiation of complementary feeding and the type of food given was also determined by social customs.

“We have this custom, Mama [maternal uncle] will give food to the child, rice, in 8th month or 9th month or 11th month. There is a puja [worship God] and then rice is given to the child.” (M-51)

Pathways of Effect

We hypothesized _a priori_ that MGNREGA will affect infant malnutrition through improving household food security and via this improve infant feeding and birth weight (fig. 1). Using path analysis we were able to estimate the effects of MGNREGA on infant malnutrition (wasting, underweight and stunting) controlling for potential confounders. Models’ assessment revealed that there was a direct pathway from MGNREGA to birth weight (i.e., not just via household food security) that had not been initially hypothesised. Further, because we found evidence that “socioeconomic status” might modify the effect of MGNREGA on household food security, we fitted separate path models to subgroups of the participants defined by their wealth index (those in the lowest 3 quintiles, the poor households, n = 317, separately from those in the top two quintiles, the non-poor households n = 211). Five models (three models with single outcome variable – wasting or stunting or underweight, and two models with all three outcomes with and without households with missing data) for each of the two sample groups (poor and non-poor) were fitted and compared using the fit indices. Robust estimates of standard error were used to take cluster sampling into account. The models with the best fit are presented in figures 2 and 3 (the model fit indices are given in the figures).
Table 4. Effect of MGNREGA on underweight, wasting and stunting.

doi:10.1371/journal.pone.0075089.t004
In the poor-MGNREGA model, the estimated effects of MGNREGA via household food security and adequate infant feeding on wasting, underweight and stunting were each 0.00 (p-value = 0.73) (table 5). However, there was evidence of a significant pathway of effect of MGNREGA on wasting and underweight through “low birth-weight” (estimated effect for wasting was $-0.10$ (Standard Error (SE) = 0.05); p = 0.047 and underweight was $-0.12$ (SE = 0.05); p = 0.033). No such effect was observed for stunting (table 5). In addition to the effect via low birth-weight, MGNREGA was found to have a direct negative effect on underweight, but not on wasting (table 5) suggesting that there could be other unidentified variables (not included in our models) in the pathway between MGNREGA and underweight.

Although there was no effect on stunting via the low birth weight pathway (table 5), a direct negative effect was estimated ($-0.17$; SE = 0.09; p = 0.056), also suggesting a possible role of other unidentified factors (fig. 2).

Unlike the poor–MGNREGA model, neither the direct nor the indirect estimated effects of MGNREGA were found to be statistically significant in the non-poor-MGNREGA model (fig. 3). However, after adjusting for other variables, a similar effect on wasting and underweight was observed through negative effects on low birth-weight, but the variable at the distal end was socioeconomic status instead of MGNREGA (fig. 3). The estimated specific indirect effect of higher socioeconomic status via low birth-weight on wasting was $-0.27$ (SE = 0.12; p = 0.023 and on underweight was $-0.33$ (SE = 0.16); p = 0.028. The estimated coefficients for the effects of MGNREGA on wasting, underweight and stunting for the poor and non-poor models are provided in table 5.

As shown in table 2, information on birth-weight of infants was missing in 121 households due to non-availability of birth records for these infants from the health centres. However, we found the households with missing observations to be evenly distributed between the MGNREGA and the non-MGNREGA groups (MGNREGA group = 59 households (21% of the total MGNREGA households) and non-MGNREGA group = 62 households (25% of the total non-MGNREGA households); p-value for $\chi^2$ test = 0.263). The reason for this missing data was non-availability of recorded birth-weights which cannot be attributed to any specific characteristics of the sample population. Further, the estimator weighted least square controlled for mean and variance (used in this study) with pair-wise deletion is considered to be an efficient and unbiased estimator for models with missing data [31]. Nevertheless, bias due to missing data cannot be completely ruled out.

**Discussion**

Among our study population in Dungarpur, Rajasthan, MGNREGA had a significant effect on reducing wasting and underweight among infants in households that participated in MGNREGA compared with households that did not. The only other study that assessed the effect of MGNREGA on child malnutrition showed a negative effect on stunting, but not on underweight and did not provide estimates for wasting [8]. Our

![Figure 2. Path model showing the effect of MGNREGA on infant malnutrition in POOR households.](doi:10.1371/journal.pone.0075089.g002)

N=317; P-value of $\chi^2$ test for model fit = 0.191; RMSEA (95%CI) = 0.03 (0.00, 0.05); Comparative fit index (CFI) = 0.96; *p<0.05; significant parameters are shown with blue arrows and non-significant ones with grey arrows. Red dotted arrows from grey dotted boxes indicate qualitative themes.
study results are comparable to that of “The Chars Livelihood Programme” in Bangladesh, a cash-for-work programme, which was shown to be associated with reduction in all the three anthropometric indicators of malnutrition in children <5 years in the participating households [11]. However, unlike the Food Consumption Survey of Niger’s public works programme which showed that children 6 to 60 months were twice as likely to be malnourished in the participating households [32], there was reduced wasting and underweight among infants in the MGNREGA employed households even after controlling for factors that influences the propensity to participate into the programme.

The findings of the focus group discussions suggested that although MGNREGA may help avoid starvation, lower than standard wages and delayed payments meant that the participants did not receive all the benefits of the programme. Several studies and programme audit reports have identified such problems related to wages and timely payments, a majority of which were attributed to corruption [10]. Contrary to our hypotheses, results from path analysis did not show that household food security and infant feeding had an effect on infant malnutrition, but did suggest a pathway of effect through birth-weight. The probability of being born with low birth-weight (<2500 grams) was lower in participating households than in non-participating households, which reduced the risk of infant malnutrition in the participating households. This suggests the possibility that the benefits of the programme function through a pathway affecting women during pregnancy. However further investigation is needed to examine this.

In our study, the economic benefits of participating in MGNREGA appear to be short term which helps to prevent acute malnutrition, but insufficient to have an effect on chronic malnutrition. This argument is supported by our finding that the effect on the anthropometric indicators of malnutrition did not vary with the number of years of participation of the households in MGNREGA. Further, the findings of the focus group discussions suggested that although MGNREGA was able to prevent hunger, the earnings were inadequate to confer household food security. Even if food security was obtained, this is unlikely to translate into adequate infant feeding because of lack of appropriate knowledge about infant feeding among the mothers in the study population. Cultural practices, societal norms and poverty played an important role in influencing mothers’ knowledge and practices. Other studies in different parts of India have also highlighted the problem of inadequate knowledge among mothers and the misconceptions prevalent with regards to infant feeding and care [33,34].

The path-models also provide an understanding of the role of the socioeconomic context in determining the effects of MGNREGA. MGNREGA is probably able to fulfil the basic nutritional requirements of pregnant women thereby reducing low birth-weight among infants in participating households compared with non-participating households in the poor socio-economic group. However, MGNREGA was not found to be effective in reducing malnutrition among infants in the comparatively better-off households. Although the results of path-analyses rely on the assumption of “no unmeasured confounding”, these are not causal models. Nevertheless, the results could have important implications for programme targeting.

**Limitations**

Cross-sectional studies provide a snap-shot of a point in time and the anthropometric indicators fluctuate across infancy and

![Path model showing the effect of MGNREGA on infant malnutrition in NON-POOR households.](https://example.com/path_model.png)

Figure 3. Path model showing the effect of MGNREGA on infant malnutrition in NON-POOR households. doi:10.1371/journal.pone.0075089.g003
there could still be residual confounding by unknown confounders. Adjusting for all known confounders identified from literature, thus selection bias cannot be completely ruled out. Further, despite unknown factors that influenced participation in MGNREGA, accounted for in the multivariable models, there could be other MGNREGA in the study population. Although this factor was status to be associated with household’s participation in the exploratory regression analysis identified below poverty line estimated. Participation in MGNREGA is through self-selection and MGNREGA against malnutrition could not have been overesti-

regression and path analysis results of protective effect of protective effect of MGNREGA on low birth-weight and thereby on infant nutrition through a maternal pathway which could be further explored in subsequent studies.

Conclusion
This study is the first we know of to analyse the effect and the pathways of effect of MGNREGA on infant malnutrition and empirically demonstrates the inter-play of the various determinants of malnutrition. However, further studies are required to measure the effect of MGNREGA on infant and child malnutrition in different social, economic and geographical settings in India and also to delineate the observed maternal pathway. Ensuring timely and adequate payment could improve food security, and augment the protective effect of the MGNREGA. Factors such as lack of mothers’ knowledge about feeding and cultural practices related to inappropriate feeding are important risk factors of infant malnutrition. Identifying and addressing such factors, over and above the social and economic policies, is key in efforts to reduce malnutrition among infants. Therefore, policies need to focus on these factors and target the persistent problem of malnutrition prevalent in India through a convergence of development, health and nutrition policies and programmes.

childhood, however, the magnitude of the logistic regression results suggest that the observed findings provide reasonable evidence. Considering that MGNREGA-households were comparatively poor (a known risk factor of malnutrition), the logistic regression and path analysis results of protective effect of MGNREGA against malnutrition could not have been overestimated. Participation in MGNREGA is through self-selection and the exploratory regression analysis identified below poverty line status to be associated with household’s participation in MGNREGA in the study population. Although this factor was accounted for in the multivariable models, there could be other unknown factors that influenced participation in MGNREGA, thus selection bias cannot be completely ruled out. Further, despite adjusting for all known confounders identified from literature, there could still be residual confounding by unknown confounders.

While the path-analyses controlled for a few determinants of low birth-weight (such as maternal age, pregnancy desired, birth-order, caste, maternal education and gender) data on other important factors such as pre-pregnancy maternal nutrition and height, obstetric history such as age at first pregnancy, inter-pregnancy intervals etc. were not available. Since the study hypothesis was concerned with child related factors, data on the maternal factors were not collected. Including these factors in the model could alter the magnitude, strength and the direction of impact of MGNREGA on low birth-weight and thereby on infant malnutrition. Nevertheless, the study generates an important hypothesis about the positive effect of MGNREGA on infant nutrition through a maternal pathway which could be further explored in subsequent studies.
