Prevalence of complementary and alternative medicine (CAM) use by the general population:

a systematic review and update

Linked Comment: Ernst. Int J Clin Pract 2012; 66: 915–6.

SUMMARY

Objectives: To update previous systematic reviews of 12-month prevalence of complementary and alternative medicine (CAM) use by general populations; to explore trends in CAM use by national populations; to develop and apply a brief tool for assessing methodological quality of published CAM-use prevalence surveys.

Design: Nine databases were searched for published studies from 1998 onwards. Studies prior to 1998 were identified from two previous systematic reviews. A six-item literature-based tool was devised to assess robustness and interpretability of CAM-use estimates. Results: Fifty-one reports from 49 surveys conducted in 15 countries met the inclusion criteria. We extracted 32 estimates of 12-month prevalence of use of any CAM (range 9.8–76%) and 33 estimates of 12-month prevalence of visits to CAM practitioners (range 1.8–48.7%). Quality of methodological reporting was variable; 30/51 survey reports (59%) met four or more of six quality criteria. Estimates of 12-month prevalence of any CAM use (excluding prayer) from surveys using consistent measurement methods showed remarkable stability in Australia (49%, 52%, 52%; 1993, 2000, 2004) and USA (36%, 38%; 2002, 2007). Conclusions: There was evidence of substantial CAM use in the 15 countries surveyed. Where national trends were discernable because of consistent measurement, there was no evidence to suggest a change in 12-month prevalence of CAM use since the previous systematic reviews were published in 2000. Periodic surveys are important to monitor population-level CAM use. Use of government-sponsored health surveys may enhance robustness of population-based prevalence estimates. Comparisons across countries could be improved by standardising approaches to data collection.

Review criteria

- Nine databases were searched from 1998 onwards; prior studies were identified from two previous systematic reviews.
- Studies were included if they reported prevalence of CAM use over 12-months in a representative sample of the general population. Studies were excluded if restricted to a single CAM therapy, or not written in English.
- A six-item tool to assess quality of published CAM-use prevalence surveys was devised and applied.

Message for the clinic

- The review included 51 reports from 49 surveys in 15 countries: estimates of 12-month prevalence of any CAM use ranged from 9.8% to 76%; and from 1.8% to 48.7% for visits to CAM practitioners.
- There was no evidence of a change in CAM use since previous reviews were published in 2000.
- Periodic surveys with consistent measurement methods are needed to determine trends in CAM use by national populations.

Introduction

It has been more than ten years since two systematic reviews of surveys of complementary and alternative medicine (CAM) use by the general public were published (1,2). The reviews concluded, independently, that despite the methodological limitations of the surveys included, CAM was used by substantial proportions of the general populations of a number of countries. One source (3) suggested that CAM use increased significantly in the USA between 1990 and 1997. A further review is timely to examine more recent trends and their implications for healthcare systems and policy as well as for consumers of CAM.

The use of all types of medicine is influenced by economic and socio-cultural factors. In economically disadvantaged societies where access to biomedical services is poor, there is evidence of a pervasive reliance on traditional healers, even for serious disease (4). In affluent countries, where biomedical services are more accessible, a substantial amount of CAM is used for illness prevention and health promotion purposes (3). There is also evidence that CAM is frequently used as an adjunct to biomedical treatment by patients with serious disease such as cancers (5,6) and to self-manage long-term health complaints like low back pain (7). However, the socio-cultural factors influencing CAM use in affluent societies are still not well understood. Studies have persistently shown that CAM users are more likely to be female, better educated, middle-aged and report poorer health status than non-users (6,8–12). CAM use appears to be
driven more by congruence with values and beliefs than by dissatisfaction with biomedicine but motivation to use CAM is further complicated by costs and benefits as experienced by consumers.

Although the true rate of CAM use can be expected to differ between countries because of economic, social and cultural factors, the prevalence rates estimated by surveys are also affected by methodological factors. Some of these have been identified with the recommendation that surveys justify the types of CAM surveyed; use pretested data collection methods; distinguish between consultations with CAM practitioners and over-the-counter products; seek reports of usage for each of the practitioner therapies and products identified; and specify the period over which CAM use is estimated (most surveys choose a 12 month retrospective period). Others have also recommended a more standardised method of collecting data to improve the comparability of CAM use estimates.

The two previous reviews of CAM prevalence each included 12 surveys for review with seven common to both studies because of differences in search methods and selection criteria. The current study has drawn on these two earlier reviews to develop more rigorous criteria for searching and selection and aims to (i) systematically review all surveys of CAM use by the general public, (ii) identify trends in CAM use by national populations, (iii) develop a brief tool for assessing methodological quality and apply it to each survey.

**Methods**

**Search strategy**

The systematic review followed the recommendations in the PRISMA statement. The following databases were searched in February 2011: MEDLINE, Medline in Process, EMBASE, Cochrane Database of Systematic Reviews, Cochrane CENTRAL Register of Controlled Trials, HTA database, Science Citation Index, AMED and PsycINFO. The search strategy combined terms for: (i) complementary and alternative medicines, (ii) prevalence, surveys or patterns of use, and (iii) population-level or national-level data. The full search strategy is provided in Appendix 1. The search was restricted to studies published from 1998 onwards. Studies published prior to 1998 were identified from two previous systematic reviews of CAM prevalence. Bibliographies of included papers were checked for further relevant studies.

Inclusion and exclusion criteria

Studies were included if they reported prevalence of CAM use over a 12-month retrospective period within a representative general population sample of a nation or a defined geographical area. Surveys of clearly-defined age groups (such as adults or children) were also included. Included studies used survey methods such as structured interviews or self-complete questionnaires. Studies were excluded if they were restricted to a single therapy (rather than CAM use overall), did not report 12-month prevalence, or were not written in English. Studies were also excluded if they were not based on representative samples of the general population; for example, surveys of sub-populations with specific clinical conditions or socio-demographic characteristics (other than age).

Study selection and data extraction

Study titles retrieved by the search were assessed for inclusion by one reviewer and a sample of excluded titles was checked by a second reviewer: no instances of discrepancy were found. Potentially relevant abstracts and full texts were assessed by two reviewers and any discrepancies resolved through discussion. Data were extracted by one reviewer and checked by a second.

Quality assessment

There is no agreed set of criteria for assessing quality of health-related surveys, although various publications have explored issues relating to the critical review of questionnaire-based surveys in health research, and previous studies of CAM-use prevalence have commented on these issues.

For the purposes of this review, we derived a short, literature-based quality assessment tool comprising important and assessable criteria of methodological quality, and applied this to each of the eligible papers identified. Our rationale for selecting quality criteria related to the need to assess the robustness and interpretability of published CAM-use estimates. Our quality criteria reflect a combination of aspects of study design, study conduct and the reporting of results.

Rationale for quality criteria

**Study design**

As with all surveys of prevalence, the estimates produced are the direct product of the questions asked; slight changes in the form of questions will have the potential to affect the resulting estimates. This is particularly important in surveys of CAM where multi-
ple, and sometimes culturally specific understandings exist in relation to the practice and to the constituent therapies (2,23). CAM prevalence surveys have employed one of two data collection methods; either a list of named therapies is presented, or more exploratory, open question(s) are used to elicit CAM use. Our first criterion required papers to reproduce the CAM survey question(s) verbatim or describe the CAM question in the text (e.g. ‘we asked about…’). For closed questions, we required a list of the pre-specified therapies (and exclusions) presented to survey respondents (described clearly enough for the individual therapies to be counted reliably). Where open question(s) were used to collect CAM-use data, we sought evidence of the content and number of open questions employed.

As the measurement process for CAM-use is complex and variable, the validity of the survey instrument is strengthened if it has been tested in a pilot study for ease of completion and comprehensibility (2,14,18). Evidence of such piloting formed our second criterion. Explicit mention of a pilot was sought for all studies, but routine, government-sponsored surveys were assumed to have undergone a piloting phase as this is standard practice and frequently described in separate, methodological papers or reports.

Adequate sample size enhances the robustness of the estimates produced and, if something is known about expected prevalence prior to the survey, a sample size calculation can be performed to ensure adequate numbers for each item of importance to be measured (18,20–22). Surveys of CAM use that are part of wider-scope studies of health behaviour tend to have large samples, but may not perform sample size calculations in relation to items measuring CAM use. Our third criterion was met if studies reported a sample of at least 1000, and/or if they reported a sample size calculation specific to CAM use.

Data collection
Previous papers have cited ‘good’ response rates for surveys as between 70–80%, and ‘acceptable’ response rates for postal surveys between 50% and 60% (18,20–22,24). Our fourth criterion was deemed to have been met if studies reported a response rate of at least 60% (we accepted adjusted or unadjusted response rates and report these in Table 1).

Analysis
Our fifth quality criterion was deemed to have been met if appropriate correction for non-response bias was used; for example, weighting the responses to the known characteristics of the original sample population (18,20–22).

Reporting of estimates
Finally, 95% confidence intervals (CIs) provide an estimate of the range within which the true prevalence value is expected to lie (18,20–22,25) and therefore provide more information whilst reducing the likelihood of ‘false’ precision being attributed to the estimates. Our sixth and final quality criterion was therefore met when studies reported 95% CIs, or standard errors (SEs) from which the CI can be calculated, for the main CAM-use prevalence estimates.

Results
Number of surveys included
The search identified 2312 unique citations, as shown in Figure 1. Of these, 2208 were excluded at the title and abstract stage, while the full texts of 104 references were examined. Forty-seven references were included in the review; three references (11,26,27) together contained reports from seven independent surveys, while four references (24,28–30) relating to two surveys gave separate reports for adults and children. In total, the 47 references reviewed contained 51 reports from 49 independent surveys. From these reports, we extracted 32 separate estimates of the 12-month prevalence of the use of any CAM and 33 estimates of the 12-month prevalence of visits to CAM practitioners.

Quality assessment
Table 1 identifies the 49 surveys ordered by the number of surveys per country, the country of origin, and the year of data collection. Each of the 51 survey reports (two surveys giving separate reports

*Parenthesis following 'Named therapies' includes number of therapists, therapies and over-the-counter products named in the survey (excludes 'other' category); following 'Open questions, parenthesis includes number of interview questions. †Piloting was assumed for government surveys. NR, data not reported
for adults and children) is assessed using the six quality criteria developed for this review.

Based on the information reported, we assessed all surveys reviewed with regards to our six quality criteria (see Table 2). The proportion of all survey reports achieving each of our criteria ranged from 43% to 84%. The criteria least likely to be met were (5) data weighting to reduce non-response bias, and (6) reporting CI or SE for key prevalence estimates. Fifty-nine percent of all survey reports met four or more of our quality criteria. Although proportionately more reports from government-sponsored surveys achieved four or more of the quality criteria compared with other survey reports, and there was a trend towards more of these reports meeting each individual criterion, the only marked difference observed was for the piloting criterion, where we made the assumption that all government-sponsored surveys were piloted. We found no evidence of an association between date of publication and quality.

Prevalence of CAM use
Table 3 is a quick access guide to CAM use over a 12-month period as reported from the 49 surveys conducted in 15 countries. It shows the percentage

| Quality criterion | All survey reports | Gvt. sponsored survey reports | Other CAM survey reports |
|-------------------|---------------------|-------------------------------|--------------------------|
|                   | n        | %  | n        | %  | n        | %  |
| 1. CAM-use measurement method clearly described | 36 | 71 | 18 | 75 | 18 | 67 |
| 2. Piloting of survey reported (or assumed for government surveys) | 35 | 69 | 24 | 100 (assumed) | 11 | 41 |
| 3. Sample size ≥ 1000 and/or sample size calculation reported | 43 | 84 | 21 | 88 | 22 | 82 |
| 4. Reported survey response rate ≥ 60% | 31 | 61 | 17 | 71 | 14 | 52 |
| 5. Data weighted to population characteristics | 27 | 53 | 16 | 67 | 11* | 41 |
| 6. 95% confidence interval or standard error reported for main prevalence estimates | 22 | 43 | 11 | 46 | 11 | 41 |
| Four or more criteria met | 30 | 59 | 20 | 83† | 10 | 37 |

*Inc. one survey (Al-Faris et al. 2008) with 95% response reported where this was deemed unnecessary.
†This includes the assumption that the pilot criterion is 100% for this group.
| Country | Age group | Survey type | Sample size (range) | All-CAM use % (year of survey) | All CAM –visits % (year of survey) | Refs, name of survey* | Meets ≥ 4 quality criteria |

of the general population using at least one type of CAM (all-CAM use), the percentage visiting any CAM practitioner (all CAM-visits), and gives an assessment of each survey using our quality criteria. Table 4 gives details for each survey of the survey population, the sampling and data collection method, the sample itself, and CAM use estimates with 95% CIs (CIs calculated by the review authors are identified). In both tables the survey data are grouped by age: adults or all ages; children; and older adults. Where possible, the following narrative identifies trends in CAM use by national populations from data obtained using consistent methodologies.

USA
Of the surveys (see Table 1) conducted in the USA from 1990 to 2007, five were government-sponsored surveys (24,31–34). Data from the National Health Interview Surveys (NHIS) provided the best available evidence of recent trends in CAM use by adults (Tables 3 and 4). Excluding prayer, all-CAM use by adults (age 18+), over a 12-month period, was estimated to be 36% in 2002 (32) and 38% in 2007 (31). Four US independent national surveys of adults (age 18+) conducted in the 1990s (3,10,35,36) estimated rates for all-CAM use of 34–42%. Visits by adults to CAM practitioners in the USA (Tables 3 and 4) increased from 13% in 2002 to 16% in 2007 with substantial variation in the use of specific CAM therapies and reported significant increases in usage of some types of therapy including acupuncture and massage therapy (31,32).

The data from the 2007 NHIS (31) indicates that all-CAM use in children (age 0–17) is considerably lower than for adults: 12% vs. 38%. The Medical Expenditure Panel Survey (MEPS) of 1996 (28) also shows that adults (age 18+) were much more likely than children (age <18) to visit CAM practitioners (8% vs. 2%). The three independent studies (37–39) of CAM use in later life (age 60+ or 65+) gave rates for all-CAM use varying from 41 to 63% (Table 3).

UK
In the UK, 12-month prevalence estimates for all-CAM use by adults in 1998 (40), 1999 (41) and 2005 (42) were 28%; 20%; and 26% respectively. Fourteen percent of the adult population (age 18+) of England were reported to have visited at least one CAM practitioner in 1998 (40). In 2001, the estimate for adults (age 16+) was 10% for England, Scotland and Wales (43), and 12% for England in 2005 (42). None of these surveys used the same measurement tool. No UK estimates for children or older adults were identified.

Canada
The National Population Health Survey (NPHS) in Canada reported rates of adult (age 15+) visits to CAM practitioners at 15% in 1995 (44) and 17% (for age 18+) in 1999 (45). Based on data from 2001–5 the Canadian Community Health Survey (CCHS) estimated that 12% of the population age 12 or older had visited some type CAM practitioner over a 12-month period (46). None of these three surveys estimated the 12-month prevalence of all CAM-use.

Australia
In Australia, the South Australian Health Omnibus Surveys (SAHOS) collected data on CAM use by adults (age 15+) living in Southern Australia in 1993, 2000 and 2004 (9,29,47). These methodologically consistent studies report remarkably similar estimates of overall CAM-use during that period (49%, 52% and 52%). Visits to CAM practitioners were reported as 20% of the population in 1993 (9), 23% in 2000 (47) and 27% in 2004 (29). As in the US, the SAHOS 2004 survey showed lower rates of overall CAM use in children (age <15) than adults (18% vs. 52%) (29,30).

Other countries
Data from survey reports in the remaining 11 countries were considered insufficient to indicate national trends in CAM use; surveys in Norway, Israel, Denmark and Singapore used inconsistent measurement methods, targeted different populations, and/or the quality of the survey reports was assessed as poor. Of surveys with national samples, the three highest rates of CAM use were reported in East Asian countries: Japan: 76%, South Korea: 75% and Malaysia: 56% (48–50).

Discussion
This is the most comprehensive and systematic review to date of surveys reporting the prevalence of CAM use by the general public. The two previous systematic reviews, published in 2000 (1,2), together included 18 reports from 17 surveys conducted in nine countries. Nine reports from the two previous reviews met the criteria for the current review, a further 40 surveys were identified yielding 42 further reports; 38 were published during or post-2000. The enduring popularity of CAM surveys was also evidenced by the number of repeat surveys conducted, particularly by government agencies, in the USA, Australia and the UK and the resultant data were used to explore trends in CAM use for this review. Reports of CAM surveys from many countries are absent and this partly reflects the limitation of excluding studies not written in English.

A total of 47 publications were reviewed containing 51 reports from 49 surveys conducted in 15 (out of a possible 196) countries. The surveys indicated that CAM was frequently used and that prevalence estimates varied widely between the 15 countries; the prevalence of all types of CAM use ranged from 9.8% to 76%, the range for visits to CAM practitioners was 1.8–48.7%. There was consistent evidence that adults were more frequent users of CAM than children; and that national estimates of CAM use were highest in East Asian countries such as Japan (48), South Korea (50), and Malaysia (49).

Prevalence estimates were also influenced by differences in methodology which make it difficult to compare figures between countries and within countries. Examples of this include variable age ranges and sampling techniques, but by far the most important source of variability which influences the comparability of estimates comes from the way in which CAM is defined and operationalised for data collection: of the 31 reports (61%) that used lists of named therapies to elicit CAM use, the number of therapies identified ranged from 4 to 36. Most surveys also allowed respondents to report the use of ‘other’ types of CAM, but CAM prevalence estimates were inflated by the inclusion of prayer as a type of CAM (32). Use of prayer was most frequently reported in studies from the USA and East Asia. Other factors contributing to high estimates of CAM use were the inclusion of religious practices other than prayer (51); named therapies not commonly regarded as CAM such as ‘dietary supplements’ (48); and the use of indigenous, traditional medicine (52). This reinforces the call for a more standardised approach to collecting comparable population data (13).

There was evidence of national trends in Australia, UK and USA. In Australia during 2004, about one in two adults and one in five children had used some type of CAM and about one in four adults had visited CAM practitioners (29,30) with no significant change in CAM use from 2000 to 2004. UK surveys also suggested that CAM use has remained fairly constant since 1998 (40) with about one in four adults using CAM and one in eight consulting a CAM practitioner during 2005 (42). In the USA, CAM use has remained steady since 2002 with the most recent survey (2007) indicating that nearly four in ten adults and one in nine children had used some type of CAM (31). However, in general, information on trends is limited by insufficient data from repeat surveys with consistent, high quality methods.

There is currently no consensus regarding ‘what is quality’ in the context of prevalence surveys. Sander-son et al. (19) argue for quality criteria focussed on the reduction of bias, but acknowledge that other
aspects of quality are important. We aimed to produce quality criteria that relate to the likely robustness and interpretability of the estimates produced. The development of the assessment tool was based on researcher experience and authoritative sources. Our experience of applying the six identified criteria suggested they had face validity, but further work is needed to establish their reliability and validity. Reliable and valid criteria can be used to select high quality surveys for future systematic reviews and to help guide the development and reporting of prevalence surveys.

Application of the six-item quality assessment tool developed for this review suggested that the quality was variable; 30 survey reports (59%) achieved four or more of the six quality criteria. There was no evidence of an association between date of publication and quality, but we did observe a trend towards higher quality in the government-sponsored surveys, according to our criteria.

The rationales cited for conducting CAM surveys in the reports reviewed were predominantly concerned with perceptions of the popularity of CAM, and its increasing use, and the implications of this for public health and health service planning. Recent surveys have revealed that delayed medical care was associated with CAM use in the USA (53); that most respondents in Australia were unaware that CAM use was not routinely tested for safety and efficacy by a government agency (29); and that more than one in four UK respondents taking prescribed drugs stated they were also using CAM (42). All of the recent reports in Australia, UK, and USA (29,31,42) emphasised the need to improve communication between physicians and patients about their use of CAM; openness and non-judgemental communication is needed to determine the risks of drug interactions and other potential complications (29). Periodic surveys of general populations are required to monitor changing patterns in CAM use as well as public perceptions and awareness, and the quality of communication between healthcare providers and their users.

Finally, most studies reviewed also reported estimates for visits to specific CAM practitioners. This will be the subject of a separate publication and complete the picture of the world-wide use of CAM based on the best available evidence.
