Transient Heat Transfer Characteristics of Twisted Structure Heated by Exponential Heat Flux

Li Wang*

School of Mechanical Engineering, Nantong University, Nantong, China

This study was conducted to investigate the transient heat transfer characteristics of a twisted structure. The twisted structure was heated according to exponential function \( Q = Q_0 \times \exp (t/\tau) \), where \( Q_0 \) is the initial heat generation rate, W/m³; \( t \) is time, s; and \( \tau \) is the period of heat generation rate. A wide range of \( \tau \) from 37 ms to 14 s was applied for the experimental study. A platinum plate with five pitches (each was 180° twisted with 20 mm in length) was used in the experiment. Helium gas with inlet temperature of 298 K under 500 kPa was used as the coolant. The heat transfer coefficient is found to increase with the decrease of \( \tau \), and the transition point was estimated to be at \( \tau \approx 1 \) s, which means that, when the increasing ratio of heat generation rate satisfies \( \frac{dQ}{dt} \geq Q_0 \cdot e^s \), the heat transfer enhancement phenomenon will be observed. The response analysis for transient heat transfer at fluid-solid interface was conducted by applying the concept of penetration depth. It is considered that, when the penetration depth is smaller than the thermal boundary thickness, the heat transfer from the interface (wall surface) to the fluid domain is not fully developed during the disturbance.

Keywords: exponential heat flux, twisted plate, transient heat transfer, forced convection, heat transfer enhancement

1 INTRODUCTION

Heat transfer enhancement technology is of great importance in industries, such as power generation industry, chemical industry, and automotive. Researchers have been committed to increase heat transfer coefficients in all types of heat exchange equipment. Detailed surveys of enhancement techniques have been made by Patil and Farkade (2016), Menni et al. (2019), Suri et al. (2018), etc. Among all these techniques, twisted tape can change the flow pattern in a channel, reduce thickness of the boundary layer, and increase the heat transfer area. Thus, many research studies focused on the flow, and heat transfer characteristics for tube with twisted inserts have been carried out.

Abbreviations: \( c_p \), specific heat of test heater [J/(kgK)]; \( c_{pH} \), specific heat of helium gas [J/(kgK)]; D, diameter of the circular channel [m]; \( g \), gravitational acceleration [m/s²]; \( h \), heat transfer coefficient [W/(m²K)]; \( k \), thermal conductivity [W/(mK)]; \( \rho \), static pressure [Pa]; \( \rho_f \), Prandtl number; \( Q \), heat generation rate per unit volume [W/m³]; \( Q_0 \), initial heat generation rate [W/m³]; \( q \), heat flux [W/m²]; \( T \), temperature [K]; \( T_s \), average temperature of the heater [K]; \( T_w \), fluid temperature at point F [K]; \( T_{ave} \), temperature of the solid tape at point \( S \) [K]; \( T_{ave} \), average temperature of wall surface [K]; \( \Delta T \), temperature difference, \( \Delta T = T_{ave} - T_w \) [K]; \( t \), time [s]; \( U \), inlet velocity [m/s]; \( X \), coordinate along the axis of the plate [m]; \( Y \), coordinate along the width of the plate [m]; \( Z \), coordinate along the thickness of the plate [m]; \( \delta \), plate (heater) thickness[m]; \( \delta_0 \), penetration depth [m]; \( \tau \), the time period of the disturbance [s]; \( \mu \), molecular viscosity [kg/(m·s)]; \( \rho \), density of helium gas [kg/m³]; \( \tau \), period of heat generation rate or e-fold time [s]; \( \tau_T \), period of surface temperature curve or e-fold time [s].
Manglik and Bergles (1993a) and Manglik and Bergles (1993b) obtained empirical correlations from wide experimental conditions for isothermal tubes with twisted tape as inserts. Saha et al. (2001) conducted experimental study for regularly spaced twisted tape–induced laminar tube flow with uniform heat flux (UHF), and the effect of tape width was discussed. Man et al. (2017) experimentally studied the heat transfer and friction characteristics of dual-pipe heat exchanger with alternation of clockwise and counterclockwise twisted tape. They suggest that this shape of twisted tape has an advantage in heat transfer enhancement over the typical twisted tapes. Kumar and Layek (2018) studied the effect of twisted rib over the absorber plate of solar air heater with a maximum enhancement for heat propagation and friction factor to be 2.58 and 1.78 times that of smooth surface, respectively. Ponnada et al. (2019) compared the thermal performance of a circular tube with twisted tapes, perforated twisted tapes, and perforated twisted tapes with alternate axis. Most of the works deal with tubes or ducts with twisted tape as inserts and study the heat transfer enhancement effect with uniform wall temperature (UWT) or UHF boundary conditions. Few studies have focused on the twisted plate itself.

Forced convection process with transient heating boundary is much more complex than the UWT or UHF boundary conditions due to the thermal response behavior in the thermal boundary layer. Cess (1961), Riley (1963), and Cotta and Özisik (1986) analytically studied the thermal response of an unsteady laminar boundary layer on a flat plate due to step changes in wall temperature and wall heat flux. These studies have been made for the case in which the velocity field is independent of time. The solution of energy equation generally adopts the energy integral equation or use similarity variables to reduce the mathematical difficulties. Khaled (2012) compared the heat transfer enhancement in laminar channel flow with four kinds of heat flux distributions: periodic step, periodic sinusoidal, linear, and exponential distribution. It was found that the maximum heating source excess temperature for the case with exponential heat flux is at most of about 22.4% lower than that with UHF over the boundary. This work proves that, with a proper heat flux distribution, additional heat can be transferred under same boundary. This work proves that, with a proper heat flux distribution, additional heat can be transferred under same

2 EXPERIMENTAL STUDY

2.1 Experimental Apparatus

The experimental apparatus consisted of gas cylinder (1), compressor (2), surge tanks (3) (9), filter (5), turbine flow meter (6), preheater (7), test section (8), cooler (8), vacuum pump (10), and the test section (7), as shown in Figure 1. The flow direction of the coolant (helium gas) is shown by arrows. A vacuum pump was used to degas the main flow loop and other branches. Helium gas was circulated by a compressor, and the fluctuations of gas flowing and pressure caused by compressor were removed with the high-capacity surge tanks that are set at both inlet and outlet of the compressor. The helium gas inside the loop was cooled by a cooler after the exit of the test section. A preheater was set before the gas flows into the test section to ensure the inlet temperature. The flow rate in the test section was measured with the turbine meter, and the system pressure was measured with a pressure transducer. The temperature of the gas at the exit of turbine flow meter and in the test section was measured by K-type thermocouples with a precision of ±1 K.

The test heater was mounted horizontally along the center axis of the circular test channel, which is made of stainless steel with inside diameter of 20 mm, as shown in Figure 2. A twisted tape with five pitches (each was 180° twisted with 20 mm in length) was used in the experiment. It was made from a platinum plate with thickness of 0.1 mm and width of 4 mm. The ends of twisted tape were connected to two copper plates and then connected to two copper electrodes. Two fine platinum wires (50 μm in diameter) were spot welded to the end parts of the twisted plate as potential conductors. The length between the potential taps is defined as the effective length on which transient heat transfer was measured.

![Figure 1: Schematic diagram of experimental apparatus](Image 313x596 to 543x712)
The twisted plate was heated by the direct current from a power source. The heat generation rate of the plate was controlled and measured by electrical control and measurement circuit. A total of four parts, namely, the double bridge circuit, the electrical control and feedback part, the signal input part, and the output data processing part, were built with connections. The double bridge circuit (also called Kelvin bridge or Kelvin double bridge) was applied to measure the resistance of the test heater to obtain the average temperature of the test heater on the basis of a calibrated temperature-resistance correlation. A high-speed analog computer was applied in part 2 to support a rapid and precise calculation-feedback process for the heat generation and heater temperature control. While the signal input and output data processing were fulfilled with a personal computer (PC) (Figure 3).

### 2.2 Experimental Method and Procedure

The experiment was conducted with the following procedure.

Before the twisted plate was installed into the test section, a calibration for temperature-resistance correlation was completed in a thermostat, with the calibration range for room temperature of up to 150°C. A calibrated correlation for the test heater was obtained.

Next, the test heater was installed horizontally along the axis of the test section with both ends connected to two copper plates and then connected to the double bridge branch. Two fine platinum wires (50 μm in diameter) were spot welded close to the end parts of the twisted plate as potential conductors and then connected to the double bridge branch.

Then, the helium gas (99.9% purity) was filled to the test loop and maintained at a certain pressure after the test loop being...
degassed by a vacuum pump. A piston compressor was used to circulate the flow in the test loop. There are two bypass branches for the test loop: one is parallel to the test section and the other goes side by side with the compressor. By adjusting the two bypass valves in the bypass branches, the flow rate could be sequentially lowered from the maximum flow rate to the desired values.

After the pressure and flow rate were confirmed to be stable at desired value in the loop, the electric current was supplied to the test heater with exponentially increasing heat generation rate controlled by the electrical control circuit. Meanwhile, the heat flux and the heater surface temperature were measured.

The uncertainties of the measurements of the heat generation rate, the heat flux of the test heater, and the heater surface temperature are estimated to be ±1%, ±2%, and ±1 K, respectively (Liu et al., 2008).

The heat flux of the heater is calculated by the following equation:

$$q = \frac{\delta}{2} \left( Q - \rho h c_h \frac{dT_a}{dt} \right)$$

where \( \rho_h, c_h, \) and \( \delta \) are the density, specific heat, and thickness of the test heater, respectively.

The instantaneous surface temperature of test heater was calculated by the following equation assuming that the surface temperature around the test heater to be uniform:

$$\alpha \frac{\partial^2 T}{\partial Z^2} + \frac{Q}{\rho h c_h} = \frac{\partial T}{\partial t}$$

Equation 2 is an unsteady heat conduction equation, which was used to calculate instantaneous surface temperature of the test heater by assuming the surface temperature around the test heater to be uniform. Boundary conditions are as follows:

$$\frac{\partial T}{\partial Z} \bigg|_{Z=0} = 0, \quad -\lambda \frac{\partial T}{\partial Z} \bigg|_{Z=d} = q$$

$$T_a = \int_{0}^{\delta} T dZ = \frac{2}{\delta} \int_{0}^{\delta} T dZ$$

where \( \alpha \) and \( \lambda \) are the thermal diffusivity and thermal conductivity, respectively. \( T_a \) is average temperature of the heater.

Experimental conditions are shown in Table 1. The twist tape has five pitches (each pitch is 180° twisted with 20 mm in length). The actual length of the twist tape is 106.4 mm, which is used in the experiment test due to manufacturing error. The inlet temperature of coolant gas (helium) is 298 K under a system pressure of 500 kPa. The flow velocity ranged from 4 to 10 m/s, and the corresponding Reynolds numbers ranged from \( 8 \times 10^3 \) to \( 2.5 \times 10^4 \). The heat generation rate was raised with exponential function. \( Q = Q_0 \exp \left( \frac{t}{\tau} \right) \), where \( Q \) is heat generation rate, W/m²; \( Q_0 \) is initial heat generation rate, W/m²; \( t \) is time, s; and \( \tau \) is period of heat generation rate, s. The period of heat generation rate ranged from 37 ms to 14 s. A smaller period means a higher increasing rate of heat generation.

### 3 EXPERIMENTAL RESULTS

Figure 4 shows the experimental data of heat generation rate applied to the twisted plate. A total of 10 periods of heat generation rate \( \tau \) were adopted ranging from 37 to 14,034 ms. As can be seen from the figure, the heat generation rate increases exponentially although some fluctuations occur at the beginning of the transient heating process. This is due to the inevitable oscillating

| Test fluid | Helium gas |
|-----------|------------|
| Helical pitch (H) | 20 mm |
| Pitch numbers | 5 |
| Total length | 106.4 mm |
| Plate width (W) | 4 mm |
| Gas temperature | 298 K |
| System pressure | 500 kPa |
| Period of heat generation rate | 37 ms–14 s |
| Flow velocity | 4–10 m/s |
| Reynolds number | 8,000–25,000 |

FIGURE 4 | The exponential heat generation rate for the twisted plate with various heat generation periods.

FIGURE 5 | The average surface temperature of the twisted plate at various heat generation periods.
of the electrical control circuit. For this reason, we used the data after the heat generation curve is stable in this research.

As can be seen in Figure 5, the average surface temperature increases exponentially as the heat generation rate increases in exponential function. By fitting the curves with an exponential function, \( C \) is a coefficient to be fitted, \( \tau_T \) is the period of the surface temperature curve, and it is observed that the period \( \tau_T \) is almost the same value with each \( \tau \) for heat generation rate, respectively, which means that a similar exponential increasing surface temperature was generated as the heat generation rate increases in exponential function.

The surface heat transfer coefficient of the twisted plate, \( h \), is defined as follows:

\[
h = \frac{q}{\Delta T} \quad \text{(5)}
\]

where \( q \) is the heat flux of the heater, which can be calculated according to Eq. 1; \( \Delta T \) is the surface temperature difference of the twisted plate, which is defined as the difference between the average surface temperature of the twisted plate \( (T_{wa}, T_{in}, T_{wa}) \) and the inlet gas temperature \( (T_{in}) \), expressed as follows:

\[
\Delta T = T_{wa} - T_{in} \quad \text{(6)}
\]

Transient heat transfer coefficient at various heat generation periods of 37, 73, 144, and 358 ms is shown in Figure 6. The flow velocity of helium gas is 4 m/s. Transient heat transfer coefficient decreases to quasi-steady value after several \( t/\tau \). With a smaller \( \tau \), the transient heat transfer coefficient is larger in both the initial decreasing region and the quasi-steady region. The quasi-steady value of transient heat transfer coefficient is defined as \( h_{qs} \).

The quasi-steady heat transfer coefficients at various heat generation periods and flow velocities are shown in Figure 7. As can be found in the figure, \( h_{qs} \) increases with the increase of flow velocity. The increasing rate at lower velocities is higher than that at higher velocities. The main reason for this is that, for higher velocities, the convective heat transfer plays a dominant role and the effect of heat conduction is of less importance than that for lower velocities. The quasi-steady heat transfer coefficient approaches asymptotic value at each velocity when \( \tau \) is longer than about 1 s. On the other hand, when the period \( \tau \) is shorter than about 1 s, \( h_{qs} \) increases as \( \tau \) shortens. When the period is relatively short, it means that the increasing rate of the heat generation rate and the surface temperature is relatively high. With fast increasing boundary temperature, the temperature gradient of the fluid in the near-wall region becomes larger compared to steady state heat transfer process, which results in a larger heat transfer coefficient. Therefore, during the transient process, temperature distribution in the thermal boundary is different compared to UWT or UHF boundary conditions. When period \( \tau \) is larger than about 1 s, the instantaneous changes in the thermal boundary become less prominent. The heat transfer process is similar to normal UWT or UHF conditions.

The Nusselt number of the twisted plate at steady state (periods ranging from 1.4 to 14 s) with flow velocity ranging from 4 to 10 m/s was compared with published empirical correlations, as the laminar analytical solution for plate (Holman, 2010), the Manglik and Bergles (1993a) correlation for tube flow with twisted tape insert, and the Dittus-Boelter correlation for tube flow (Faghri et al., 2010).

\[
Nu_L = 0.664Re^{0.8}Pr^{0.38} \quad \text{Plate (Laminar)} \quad \text{(7)}
\]

\[
Nu_L = 0.106 \times \left(1 + \left(\frac{\pi}{2y}\right)^{0.5}\right)^{0.767} Re^{0.5} Pr^{0.3} \quad \text{Manglik and Bergles} \quad \text{(8)}
\]

\[
Nu = 0.023Re^{0.8}Pr^{0.4} \quad \text{Dettus – Boelter} \quad \text{(9)}
\]

As shown in Figure 8, by comparing the Nu for the twisted plate with flat plate, it is about 3.2 times higher at Reynolds number of 15,000. With the increase of Re, the twisted plate shows even better performance. For tube flows without any inserts as the Dittus-Boelter correlation shows, the Nu is the lowest. The experimental data for twisted plate is about 5.2 times of the tube flow at Reynolds number of 15,000.

\[
\frac{Nu_{plate}}{Nu_{tube}} = 5.2 \quad \text{at Reynolds number of 15,000} \quad \text{(10)}
\]

\[
Re = \frac{u D}{v} \quad \text{(11)}
\]
number of 15,000. When we compare the experimental data with Manglik and Bergles correlation, the Nusselt number is about twice the value. This is because the experimental result for Nu in this study is for the twisted plate itself, whereas in the Manglik and Bergles correlation, the Nu is for the tube with twisted plate as inserts. The Manglik and Bergles correlation was obtained for Re ranged from 300 to 30,000. The twist ratio γ (γ = H/W, where H is 180° twist pitch and W is width) is 3–6.

4 RESPONSE ANALYSIS FOR HEAT TRANSFER INTERFACE OF SOLID AND FLUID AREA

To help understand the heat transfer response for transient heat transfer process, we now carry out a simple analysis for fluid-solid coupled transient heat transfer procedure. A near-wall point in the fluid domain is set as point F, and a near-wall point in the solid domain is set as point S, as shown in Figure 9. During the transient process, physical parameters such as temperature and conductivity vary with time, so as the variables at the interface (wall surface). Taking a simple finite difference to approximate the heat fluxes for both sides, we then have a discrete form of the physical heat flux and temperature continuity across the interface.

\[
k_f \left( \frac{T_w - T_s}{\Delta x_f} \right) = k_s \left( \frac{T_s - T_w}{\Delta x_s} \right)
\]

(10)

The wall temperature can thus be represented in terms of updated \( T_w \) and \( T_s \):

\[
T_w = T_{w0} + \Delta T_w
\]

(13)

where \( \Delta T_w \) is the fluctuation.

The key to the accuracy and consistency of the wall temperature fluctuation value \( T_w \) is how fast the temperature disturbance can propagate in the near-wall boundary layer of fluid. For one-dimensional semi-infinite domain, penetration depth was suggested by Faghri et al. (2010).

\[
\delta_p = \sqrt{8 \alpha \delta_t}
\]

(14)

The time scale \( \delta_t \) is given by the time period of the disturbance. Take the diffusivity \( \alpha \) for helium gas and suppose \( \delta_t \) as 1 ms, the penetration depth is about 0.57 mm, which might be smaller than the thermal boundary thickness. When the penetration depth is smaller than the thermal boundary thickness, heat transfer from solid domain to fluid domain is not fully developed during the disturbance. The wall temperature is lower due to the lower \( T_w \) and thus results in higher heat transfer coefficient.

For this research with exponential increasing heat input, it is considered that, with a fixed Pr, the increasing rate of heat generation rate is the main effect that affects the quasi-steady heat transfer coefficient. On the basis of all these research studies, we would like to take \( \tau \approx 1 \) s as the transition point, which means that, when the increasing rate of heat generation rate is large enough \((dQ/dt) \geq Q_0 \cdot \epsilon\), the heat transfer enhancement phenomenon will be observed.

According to our early research, it is observed that the transition point of period \( \tau \) for heat transfer coefficient does not show much dependence on velocity because we have rose up the flow velocity to 150 m/s in a narrow channel (Liu et al., 2017). Besides, the effects of gas pressure, initial gas temperature, initial heat generation rate, and structure of the heating surface on transition point are not obvious according to this research and our wide range experiments (Liu et al., 2008; Liu et al., 2014; Liu et al., 2017). Early research by Chao and Cheema (1967) indicated that the response time of the thermal layer due to a step change in wall flux varies directly as \( \text{Pr}^{1/3} \) with Pr ranged from 0.72 to 100. The research by Khaled (2012) also suggested that...
the monotonic heat flux increase effect tends to increase the heat transfer coefficient due to the associated increase in the temperature difference near boundary. However, the heat flux discussed in this research is spatial dependent, not time dependent.

5 CONCLUSION

Forced convection transient heat transfer for helium gas flowing over a twisted plate with exponential increasing heat input was experimentally studied. The following conclusions were obtained.

1) Surface temperature difference increases exponentially with the same period as the heat generation rate increases with exponential function.
2) The heat transfer coefficient approaches the quasi-steady state one after a large enough heat generation period of about 1 s, and it becomes higher for a small period less than about 1 s.
3) It is estimated that, when the increasing rate of heat generation rate is high enough (\(\frac{\text{d}Q}{\text{d}t} \geq Q_0 \cdot e^t\)), the heat transfer enhancement effect will be observed.

4) The heat transfer enhancement characteristics were discussed with penetration depth.
