ENUMERATION AND LIMIT LAWS OF SERIES-PARALLEL GRAPHS

MANUEL BODIRSKY, OMER GIMÉNEZ, MIHYUN KANG, AND MARC NOY

Abstract. We show that the number $g_n$ of labelled series-parallel graphs on $n$ vertices is asymptotically $g_n \sim g \cdot n^{-1/2} \gamma^n n!$, where $\gamma$ and $g$ are explicit computable constants. We show that the number of edges in random series-parallel graphs is asymptotically normal with linear mean and variance, and that the number of edges is sharply concentrated around its expected value. Similar results are proved for labelled outerplanar graphs and for graphs not containing $K_{2,3}$ as a minor.

1. Introduction

A graph is series-parallel (SP for short) if it does not contain the complete graph $K_4$ as a minor; equivalently, if it does not contain a subdivision of $K_4$. Since both $K_5$ and $K_{3,3}$ contain a subdivision of $K_4$, by Kuratowski’s theorem a SP graph is planar. Another characterization, justifying the name, is the following. A connected graph is SP if it can be obtained from a single edge by means of the the following two operations: subdividing an edge (series extension); and duplicating an edge (parallel extension). In addition, a 2-connected graph is SP if it can be obtained from a double edge by means of series and parallel extensions; in particular, this implies that a 2-connected SP graph has always a vertex of degree two. Although SP operations may give rise to multiple edges, in this paper all graphs considered are simple. Yet another characterization is that SP graphs are precisely the graphs with tree-width at most two. Equivalently they are subgraphs of 2-trees, where a 2-tree is a graph formed by, starting from a triangle, adding repeatedly a new vertex and joining it to an existing edge.

An outerplanar graph is a planar graph that can be embedded in the plane so that all vertices are in the outer face. They are characterized as those graphs not containing a minor isomorphic to (or a subdivision of) either $K_4$ or $K_{2,3}$. They constitute an important subclass of the class of SP graphs.

Series-parallel graphs have been widely studied in graph theory and computer science. They are simple in structure but yet rich enough so that several theoretical and computational problems are still unsolved on SP graphs. In fact, they are often used as a benchmark for analyzing the complexity of graph theoretical problems. The same thing can be said, maybe even more, about outerplanar graphs.

In this paper we study the enumeration of labelled series-parallel and outerplanar graphs. From now on, unless stated otherwise, all graphs are labelled. Next we summarize what is known about this problem. An SP graph on \( n \) vertices has at most \( 2n - 3 \) edges. Those having this number of edges are precisely the 2-trees; it is known \([8]\) that the number of labelled 2-trees on \( n \) vertices is equal to \((\frac{n}{2})(2n - 3)^{n-4}\). On the other hand, an outerplanar graph is 2-connected if and only if it has a unique Hamilton cycle. It follows that a 2-connected outerplanar graph is in fact equivalent to a dissection of a convex polygon, the boundary of the polygon being the unique Hamilton cycle. Hence counting 2-connected outerplanar graphs amounts essentially to counting dissections of a convex polygon, a classical and well-known problem that we revisit in Section 5. It is also worth mentioning that an outerplanar map (a map is a planar graph together with a particular embedding in the plane) on \( n \) vertices can be encoded with \( 3n \) bits \([2]\); hence the number of outerplanar graphs is at most \( 2^{3n} = 8^n \).

The main goal of this paper is to give precise asymptotic estimates for the number of SP and outerplanar graphs. In Section 2 we show that the number \( b_n \) of 2-connected SP graphs is asymptotically of the form
\[
b_n \sim b \cdot n^{-5/2} R^{-n} n!,
\]
where \( b \) and \( R \approx 0.12800 \) are computable constants. Then in Section 3 we show that the total number \( g_n \) of SP graphs is given by
\[
g_n \sim g \cdot n^{-5/2} \rho^{-n} n!,
\]
where \( \rho \approx 0.11021 \).

In Section 2 we analyze the distribution of the number of edges in SP graphs. If \( X_n \) is the random variable equal to the number of edges in a random SP graph, we prove that \( X_n \) is asymptotically normal and that the mean \( \mu_n \) and variance \( \sigma_n^2 \) of \( X_n \) satisfy
\[
\mu_n \sim \kappa n, \quad \sigma_n^2 \sim \lambda n,
\]
where \( \kappa \approx 1.61673 \) and \( \lambda \approx 0.55347 \). As a consequence, the number of edges is sharply concentrated around its expected value.

In Section 4 we study the same problems for outerplanar graphs. We prove that the number \( h_n \) of outerplanar graphs is
\[
h_n \sim h \cdot n^{-3/2} \sigma^{-n} n!,
\]
where \( \sigma \approx 0.13659 \), and that the number of edges in random outerplanar graphs is asymptotically normal with mean variance
\[
\mu_n \sim \zeta n, \quad \sigma_n^2 \sim \eta n,
\]
where \( \zeta \approx 1.56251 \) and \( \eta \approx 0.22399 \). Previously, it had been shown \([3]\) that \( \zeta \geq 7/5 \).

In Section 5 we study the distribution of the number of connected components in series-parallel and outerplanar graphs. In both cases it turns out that the distribution is asymptotically a shifted Poisson law with parameter equal to \( \nu = 0.117614 \) for SP graphs, and \( \xi = 0.14840 \) for outerplanar graphs. As a consequence the probability that a random SP graph is connected tends to \( e^{-\nu} = 0.889038 \), and to \( e^{-\xi} = 0.86208 \) for outerplanar graphs.

Finally, in Section 6 we study the family of graphs not containing \( K_{2,3} \) as a minor. This is a subfamily of series-parallel graphs which turns out to be very close to the family of outerplanar graphs.
The proofs are based on singularity analysis of generating functions and perturbation of singularities (see [4, 5]), and on several ideas developed in [1] and [7] for solving similar problems for the class of planar graphs. For the techniques and results of singularity analysis used in the sequel we refer to the forthcoming book Analytic Combinatorics by Flajolet and Sedgewick [5].

2. COUNTING TWO-CONNECTED SERIES-PARALLEL GRAPHS

Let \( b_{n,q} \) be the number of 2-connected SP graphs with \( n \) vertices and \( q \) edges, and let

\[
B(x, y) = \sum b_{n,q} y^q x^n/n!
\]

be the corresponding exponential generating function (EGF).

Following [9], we define a network as a graph with two distinguished vertices, called poles, such that adding the edge between the poles the resulting multigraph is 2-connected. If \( D(x, y) \) is the EGF for SP networks, where again \( x \) marks vertices and \( y \) marks edges then, as shown in [9], we have

\[
(2.1) \quad \frac{\partial B(x, y)}{\partial y} = \frac{x^2}{2 \left( 1 + D(x, y) (1 + y) \right)}.
\]

Since a 2-connected SP graph has always a vertex of degree two, it follows that there are no 3-connected SP graphs; in the terminology of [9] there are only s-networks and p-networks and there are no h-networks. Hence equation (12) in [1] simplifies to

\[
(2.2) \quad \log \left( \frac{1 + D}{1 + y} \right) = \frac{xD^2}{1 + xD}
\]

Our goal is to perform a complete singularity analysis of \( B(x, y) \) using equations (2.1) and (2.2). To this end we first determine the singularities of \( D(x, y) \).

From now on \( y \) is a fixed positive value. Because of (2.2), the inverse of \( D(x, y) \) as a function of \( x \) is given by

\[
\psi_y(u) = \frac{\log \left( \frac{1+u}{1+y} \right)}{u \left( u - \log \left( \frac{1+u}{1+y} \right) \right)}.
\]

We show that the equation \( \psi'_y(u) = 0 \) has a unique positive root \( u = \nu(y) \) for every positive \( y \). (We often write \( \psi \) and \( \nu \) instead of \( \psi_y \) and \( \nu(y) \) for brevity.) Hence \( D(x, y) \), being the inverse of \( \psi \), ceases to be analytic at \( x = R(y) = \psi(\nu) \). By Proposition IV.4 in [4], it follows that the dominant singularity of \( D(x, y) \) for fixed \( y \) is at \( R(y) \). The next result gives a procedure for obtaining \( R(y) \) as a function of \( y \). But first we need a technical lemma, analogous to Lemma 2 in [1].

Lemma 2.1. The function

\[
Y(t) = \frac{1}{1-t^2} \exp \left( -\frac{t^2}{1+t} \right) - 1
\]

has an analytic inverse in the domain \( t \in (0, 1) \).

Proof. It is enough to see that \( Y(t) \) is an increasing function in \( t \in (0, 1) \), and this is so because

\[
Y'(t) = \frac{(t+3)t^2}{(t^2-1)^2(1+t)} \exp \left( -\frac{t^2}{1+t} \right) > 0.
\]
Theorem 2.2. For fixed $y > 0$, the dominant singularity of $D(x, y)$ is at $R(y) = q(t)$, where

(2.3) \[ q(t) = \frac{(1 + t)(t - 1)^2}{t^3}, \]

and $t$ is the unique root of $Y(t) = y$, where $Y(t)$ is as in Lemma 2.1.

Proof. Let

(2.4) \[ L = L(u) = \log \left( \frac{1 + u}{1 + y} \right). \]

A routine computation gives

\[ \psi'(u) = \frac{(1 + u)L^2 - 2u(1 + u)L + u^2}{(1 + u)u^2(L - u)^2}. \]

The numerator vanishes when the corresponding quadratic equation on $L$ has a root, necessarily at $u = \psi'(u)$. This gives

(2.5) \[ L(\psi'(u)) = \frac{2\psi'(u)}{1 + t} = \frac{2\psi'(u)}{1 + t} \]

In order to simplify (2.5), we set $t = \sqrt{\frac{u}{1 + u}}$ so that $u = t^2/(1 - t^2)$. Equations (2.4) and (2.5) then become

(2.6) \[ D(x, y) = D_0(y) + D_1(y)X + D_2(y)X + O(X^3), \]

where $X = \sqrt{1 - x/R(y)}$.

Lemma 2.3. For fixed $y > 0$, the singular expansion of $D(x, y)$ at $R(y)$ is

(2.7) \[ D(x, y) = D_0(y) + D_1(y)X + D_2(y)X + O(X^3), \]

where $X = \sqrt{1 - x/R(y)}$ and

\[ D_0 = \frac{t^2}{1 - t^2}, \quad D_1 = \frac{\sqrt{2t^3}}{\sqrt{t + 3(t^2 - 1)}}, \quad D_2 = \frac{2t(t^2 + 3t + 3)}{3(1 - t)(3 + t)^2} \]

where $t$ is the unique root of $Y(t) = y$. 

□
Proof. The constant term is $D_0 = D(R(y), y) = v$, and the terms $D_1$ and $D_2$ are
\[ D_1 = -\sqrt{-2/R(y)} \psi''(v), \quad D_2 = \frac{R\psi'''(v)}{3\psi''(v)^2}, \]
where these expressions can be obtained by inverting the Taylor series of $\psi(u)$ at the point $u = v$ where $\psi'(v)$ vanishes.

Now we use Maple to compute $\psi''(u)$ and $\psi'''(u)$, which are rational expressions on $u$ and $L$. Then we set $u = t^2/(1 - t^2)$ and $L = t^2/(1 + t)$, and simplifying we obtain
\[ \psi''(t) = -\frac{(t + 3)(t - 1)^3(1 + t)^3}{t^6}, \]
\[ \psi'''(t) = -\frac{2(t^2 + 3t + 3)(t - 1)^5(1 + t)^5}{t^8}. \]
Hence $\psi''(t) < 0$ for $t \in (0, 1)$, and we use this expressions to obtain $D_1$ and $D_2$ in terms of $t$. □

After completing the analysis of $D(x,y)$ we turn to that of $B(x,y)$. The first thing is to express $B$ in terms of $D$.

Lemma 2.4. The following holds, where $D = D(x,y)$:
\[ B(x,y) = \frac{1}{2} \log(1 + xD) - \frac{x(D(x^2D^2 + xD + 2 - 2x))}{4(1 + xD)}. \]
Proof. We follow the proof of Lemma 5 in [GN]. From now on $x$ is a fixed value. From (2.4) it follows that
\[ B(x,y) = \frac{x^2}{2} \log(1 + y) + \frac{x^2}{2} \int_0^y \frac{D(x,t)}{1 + t} dt. \]
Integrating by parts we get
\[ \int_0^y \frac{D(x,t)}{1 + t} dt = \log(1 + y)D - \int_0^y \log(1 + t) \frac{\partial D}{\partial t} dt. \]
Now we notice that the inverse of $D$ with respect to $y$ is
\[ \phi(u) = -1 + (1 + u) \exp \left( -\frac{xu^2}{1 + xu} \right). \]
The last integral, after the change $s = D(x,t)$ becomes
\[ \int_0^{D(x,y)} \left( \log(1 + s) - \frac{xs^2}{1 + xs} \right) ds, \]
which can be integrated in elementary terms. The rest of the computation is routine and the claim follows. □

In view of the expression in Lemma 2.4 it is clear that, for fixed $y$, the dominant singularity of $B(x,y)$ is the same as that of $D(x,y)$, namely $R(y)$. Using (2.7) we can find the singular expansion of $B(x,y)$.

Lemma 2.5. For $y$ fixed closed to 1, the singular expansion of $B(x,y)$ at its singularity $R(y)$ is
\[ B(x,y) = B_0(y) + B_2(y)X^2 + B_3(y)X^3 + O(X^4), \]
where $X = \sqrt{1 - x/R(y)}$ and $B_0(y), B_2(y), B_3(y)$ are the following analytic functions of the unique root $t$ of $Y(t) = y$. \[ \text{(2.8)} \]
\[
B_0(t) = \frac{t^3 + 2 \ln(1/t) t^3 + 2t^2 - 5t + 2}{4t^3}
\]
\[
B_1(t) = \frac{(t - 1)^3(t + 2)}{2t^3}
\]
\[
B_3(t) = (1 - t)^3 \sqrt{\frac{2}{3(t + 3)t^3}}
\]

Proof. It is enough to set \( x = R(1 - X^2) \) and \( D = D_0 + D_1 X + D_2 X^2 + D_3 X^3 \) in (2.7). All the calculations have been performed with Maple. In particular, we obtain that \( B_1 \) vanishes identically as a function of \( t \), and that \( B_3 \) does not depend on the value of \( D_3 \). □

Theorem 2.6. The number of 2-connected SP graphs \( b_n \) is asymptotically

\[
b_n \sim b \cdot n^{-5/2} \cdot R^{-n} n!
\]

where \( R = R(1) \approx 0.12800 \) and \( b \approx 0.0010131 \).

Proof. By transfer theorems, the asymptotic estimate follows from the singularity expansion of \( B(x, 1) \) of Lemma 2.5. Solving \( Y(t) = 1 \) gives \( t \approx 0.80703 \), and from here we obtain the values of \( R(1) = q(t) \) and of \( b = 3B_3(t)/(4\sqrt{\pi}) \). □

3. Counting series-parallel graphs

Recall that \( g_n, c_n \) and \( b_n \) denote, respectively, the number of SP graphs, connected SP graphs, and 2-connected SP graphs on \( n \) vertices. Adapting the proof of Lemma 1 in [7], we obtain that the corresponding exponential generating functions are related as follows.

Lemma 3.1. The series \( G(x), C(x) \) and \( B(x) \) satisfy the following equations:

\[
G(x) = \exp(C(x)), \quad xC'(x) = x \exp(B'(xC'(x))),
\]

where \( C'(x) = dC(x)/dx \) and \( B'(x) = dB(x)/dx \).

Let \( b_{n,q} \) be the number of 2-connected planar graphs with \( n \) vertices and \( q \) edges, and let

\[
B(x, y) = \sum b_{n,q} y^n x^n / n!
\]

be the corresponding bivariate generating function. Notice that \( B(x, 1) = B(x) \).

The generating functions \( C(x, y) \) and \( G(x, y) \) are defined analogously. Since the parameter “number of edges” is additive under taking connected and 2-connected components, the previous lemma can be extended as follows.

Lemma 3.2. The series \( G(x, y), C(x, y) \) and \( B(x, y) \) satisfy the following equations:

\[
G(x, y) = \exp(C(x, y)), \quad x \frac{\partial}{\partial x} C(x, y) = x \exp \left( \frac{\partial}{\partial x} B(x \frac{\partial}{\partial x} C(x, y), y) \right).
\]

Let \( F(x, y) = xC'(x, y), \) where the derivative is with respect to the first variable. Lemma 3.1 implies that

\[
F(x, y) = x \exp(B'(F(x, y), y)).
\]
It follows that, for fixed \( y \), the functional inverse of \( F(x, y) \) is

\[ \Psi_y(u) = ue^{-B'(u, y)}. \]

The function \( \Psi_y \) should not be confused with \( \psi_y \) in Section 2, although it plays a similar role. Our goal is to prove that for each \( y > 0 \), \( \Psi_y(u) = 0 \) has a root \( \tau(y) \).

As in the previous section we often omit the fact that \( \Psi \) and \( \tau \) depend on a fixed \( y \).

**Lemma 3.3.** The equation

\[ D^6u^3 + D^5u^3 + 2D^3u^2 + 4D^2u - 2 = 0, \]

where \( D = D(u, y) \) and \( y \) is a fixed positive value, has a unique solution \( u = \tau(y) \) in \((0, R(y))\).

**Proof.** Let \( T(u, D) = T(u, y) \) be the left hand side of (3.1), which is an increasing function of \( u \) since \( D(u, y) \) has non-negative coefficients. Since \( T(0, y) = -2 \), it follows that \( \tau \) exists and is unique if and only if \( T(R(y), y) > 0 \). We use the expressions in terms of \( t \) for \( R(y) \) and \( D(R(y), y) \) given in Theorem 2.2 and Lemma 2.3 and, after simplification, we obtain that \( T(R(y), y) \) written as a function of \( t \) is

\[ \frac{1 - t}{(1 + t)^2}. \]

This is a positive value when \( t \in (0, 1) \), so the claim follows. \( \square \)

**Theorem 3.4.** Let \( y \) be a fixed positive value. The unique root of \( \Psi'(u) = 0 \) is given by \( \tau(y) \) in Lemma 3.3. The dominant singularity of \( F(x, y) \) is at \( \rho(y) \), where \( \rho \), as a function of \( \tau \), is

\[ \rho(\tau) = \tau \exp\left(\frac{\tau D(\tau D^2 - 2)}{2(1 + \tau D)}\right), \]

where \( D = D(\tau(y), y) \).

The singular expansion of \( F(x, y) \) at its dominant singularity \( \rho(y) \) is

\[ F(x, y) = F_0(y) + F_1(y)X + O(X^2), \]

where \( X = \sqrt{1 - x/\rho(y)} \) and

\[
\begin{align*}
F_0(\tau) &= \tau \\
F_1(\tau) &= \frac{2 - 2\tau D^2 - \tau^2 D^3}{D} \sqrt{\frac{\tau(1 + \tau D)}{S}} \\
S &= -4\tau^5D^7 - 5\tau^4D^6 + (6\tau^4 - \tau^3)D^5 + 5\tau^3D^4 - 3\tau^2D^3 + 6\tau^2D^2 + 12\tau D + 4
\end{align*}
\]

**Proof.** We start by differentiating \( \Psi(u) \):

\[ \Psi'(u) = \exp(-B'(u, y))(1 - uB''(u, y)). \]

By Lemma 2.4 the functions \( \Psi(u) \) and \( \Psi'(u) \) can be written in terms of \( D = D(u, y) \),

\[
\begin{align*}
\Psi(u) &= u \exp\left(\frac{uD(uD^2 - 2)}{2(1 + uD)}\right) \\
\Psi'(u) &= \frac{u^4D^6 + u^3D^5 + 2u^2D^3 + 4uD^2 - 2}{(2u^2D^3 + 4uD^2 - 2)(1 + uD)} \exp\left(\frac{uD(uD^2 - 2)}{2(1 + uD)}\right),
\end{align*}
\]
where $D = D(u, y)$. To obtain the previous expressions we have used the relation

$$D' = \frac{D^2(1 + D)}{1 - 2uD^2 - u^2D^3},$$

which follows directly from (2.2).

Hence the root $u = \tau(y)$ of $\Psi'(u)$ is the one given by Lemma 3.3. As for the remaining expressions, $\rho(y)$ is $\Psi(\tau), F_0(y)$ is just $\tau$, and $F_1(y)$ is given by $-\sqrt{-2\Psi(\tau)/\Psi''(\tau)}$, if we can show that $\Psi''(\tau) < 0$. To obtain $\Psi''(\tau)$ we differentiate $\Psi'(u)$ with respect to $u$. Note that, when evaluating at $u = \tau$, the polynomial $T(u, D)$ vanishes, and so

$$\Psi''(\tau) = \frac{\partial T}{\partial u}(\tau, D) + \frac{\partial T}{\partial D}(\tau, D)D' \exp\left(\frac{\tau D(\tau D^2 - 2)}{2(1 + \tau D)}\right).$$

All factors in this expression are positive but for $2\tau^2D^3 + 4\tau D^2 - 2 < T(\tau, D) = 0$, hence we have shown that $\Psi''(\tau) < 0$. The expression for $F_1(\tau)$ follows by straightforward simplification.

In order to find the singular expansion of $C(x, y)$, we start with a simple lemma.

**Lemma 3.5.** The following holds:

\begin{equation}
C(x, y) = F(x, y)(1 + \log x - \log F(x, y)) + B(F(x, y), y)
\end{equation}

Proof. This result is given in the proof of Theorem 1 in [GN]. It is analogous to that of Lemma 2.4 but simpler. Since $F(x, y) = xC'(x, y)$, we have that

$$C(x, y) = \int_0^x \frac{F(s, y)}{s} ds = F(x) \log x - \int_0^x F'(s, y) \log s ds.$$ 

Now we change variables $t = F(s)$, so that $s = \Psi(t) = t \exp(-B'(t, y))$. Then the last integral becomes

$$\int_0^{F(x, y)} \log \Psi(t) \, dt = \int_0^{F(x, y)} (\log t - B'(t, y)) \, dt.$$ 

Hence

$$C(x, y) = F(x, y)(1 + \log x - \log F(x, y)) + B(F(x, y), y).$$

\[\square\]

**Theorem 3.6.** Let $y$ be a fixed positive value. The dominant singularities of $C(x, y)$ and $G(x, y)$ are at $\rho(y)$, where $\rho(y)$ is as in Theorem 3.4. The singular expansions of $C(x, y)$ and $G(x, y)$ at their singularities are

$$C(x, y) = C_0(y) + C_2(y)X^2 + C_3(y)X^3 + O(X^4),$$

$$G(x, y) = G_0(y) + G_2(y)X^2 + G_3(y)X^3 + O(X^4),$$

where $X = \sqrt{1 - x/\rho(y)}$ and

$$C_0 = \tau(\log \rho - \log(\tau) + 1) + B(\tau, y), \quad C_2 = -F_0, \quad C_3 = -\frac{3}{2}F_1,$$

$$G_0 = \exp(C_0), \quad G_2 = \exp(C_0)C_2, \quad G_3 = \exp(C_0)C_3.$$
By equating coefficients the expressions for $C_\alpha n$ number of edges is asymptotically normal and that the expected value evaluate as for Theorem 2 from [7]. The exact form we need of the Quasi-Powers theorem allows to deduce a normal limit law for a combinatorial parameter from the bivariate singular expansion of the corresponding generating function. The proof scheme is as for Theorem 2 from [7].

Finally, the singular expansion of $G(x, y)$ follows from $G(x, y) = \exp(C(x, y))$, since

$$G(x, y) = \exp(C_0) \exp(C_2X^2 + C_3X^3) + \mathcal{O}(X^4) = \exp(C_0)(1 + C_2X^2 + C_3X^3) + \mathcal{O}(X^4).$$

\[\square\]

**Theorem 3.7.** The number of connected SP graphs $c_n$ and all SP graphs $g_n$ are asymptotically

$$c_n \sim c \cdot n^{-5/2} \cdot \rho^{-n} n!$$

$$g_n \sim g \cdot n^{-5/2} \cdot \rho^{-n} n!$$

where $\rho = \rho(1) \approx 0.11021$, $c \approx 0.0067912$ and $g \approx 0.0076388$.

**Proof.** The asymptotic estimates follow again from transfer theorems on the generating functions $C(x, 1)$ and $G(x, 1)$. As for the constants, solving Equation 3.1 in Lemma 3.1 for $y = 1$ yields $\tau(1) \approx 0.1279695$ and $D(\tau(1), 1) \approx 1.84351$, and from here follow the values of $\rho = \Psi(\tau), c = 3C_3/(4\sqrt{\pi})$ and $g = \exp(C_0)c$. \[\square\]

**4. The Number of Edges in Series-Parallel Graphs**

The main tool in this section is the so-called Quasi-Powers theorem [5], which allows to deduce a normal limit law for a combinatorial parameter from the bivariate singular expansion of the corresponding generating function. The proof scheme is as for Theorem 2 from [7]. The exact form we need of the Quasi-Powers theorem is that of Proposition 2 in [7].

We work out in some detail the case of 2-connected SP graphs; the remaining cases follow the same pattern. We know that for fixed $y$ we have a singular expansion

$$B(x, y) = B_0(y) + B_2(y)X^2 + B_3(y)X^3 + \mathcal{O}(X^4),$$

where $X = \sqrt{1 - x/R(y)}$ and the $B_i$ are analytic functions. We deduce that number of edges in 2-connected graphs is normally distributed and that the expected number of edges is asymptotically $\alpha n$, where

$$\alpha = -\frac{R'(1)}{R(1)} \approx 1.71891.$$

The derivative $R'(1)$ is computed using the explicit form of $R(y)$ given in Theorem 2.2 indeed $R'(y) = q'(t)/Y'(t)$, where $t$ is the unique solution of $Y(t) = y$. The relevant values are $R(1) = 0.12800$ and $R'(1) = -0.22002$.

The variance is asymptotically $\beta n$, where

$$\beta = -\frac{R''(1)}{R(1)} - \frac{R'(1)}{R(1)} \left( \frac{R'(1)}{R(1)} \right)^2.$$

We compute $R''(1) = 0.57667$, so that $\beta \approx 0.16846$. Hence we have proved:
Theorem 4.1. Let $X_n$ denote the number of edges in a random 2-connected series-parallel graph with $n$ vertices. Then $X_n$ is asymptotically normal and the mean $\mu_n$ and variance $\sigma^2_n$ satisfy
\[
\mu_n \sim \kappa_0 n, \quad \sigma^2_n \sim \lambda_0 n,
\]
where $\kappa_0 \approx 1.71891$ and $\lambda_0 \approx 0.16846$.

It is worth recalling that the number of edges in a 2-connected SP graph is between $n$ and $2n - 3$.

For connected SP graphs and arbitrary SP graphs the same result holds, but in this case the dominant singularity is at $\rho(y)$, which is given in Theorem 3.3.

Theorem 4.2. Let $X_n$ denote the number of edges in a random series-parallel graph with $n$ vertices. Then $X_n$ is asymptotically normal and the mean $\mu_n$ and variance $\sigma^2_n$ satisfy
\[
\mu_n \sim \kappa n, \quad \sigma^2_n \sim \lambda n,
\]
where $\kappa \approx 1.61673$ and $\lambda \approx 0.21125$. The same is true, with the same constants, for connected random SP graphs.

Since $\sigma_n = o(\mu_n)$ it follows that the number of edges in random SP is concentrated around its expected value, in the sense that for every $\epsilon > 0$ we have
\[
\Pr\{|X_n - \kappa n| > \epsilon n\} \to 0, \quad \text{as } n \to \infty.
\]
This comment also applies to Theorem 4.1 and to the Gaussian limit laws presented in the next sections.

Proof. Since $\rho(y) = \Psi(\tau(y), y)$ it follows that
\[
\rho'(y) = \frac{\partial \Psi}{\partial x}(\tau(y), y) \tau'(y)(y) + \frac{\partial \Psi}{\partial y}(\tau(y), y) = \frac{\partial \Psi}{\partial y}(\tau(y), y),
\]
where the first summand vanishes by definition of $\tau(y)$. We can compute $\partial \Psi/\partial y$ explicitly by differentiating $\Psi(u, y)$ with respect to $y$, and using that
\[
\frac{\partial D}{\partial y}(x, y) = -\frac{(1 + xD(x, y))^2(1 + D(x, y))}{(-1 + 2xD(x, y)^2 + x^2D(x, y)^3)(1 + y)}.
\]
We obtain that $\rho'(1) \approx -0.17818$.

To compute $\rho''(1)$ we proceed in a similar way,
\[
\rho''(y) = \frac{\partial^2 \Psi}{\partial x \partial y}(\tau(y), y) \tau'(y)(y) + \frac{\partial^2 \Psi}{\partial y^2}(\tau(y), y).
\]
Computing the partial derivatives of $\Psi$ poses no problem; to obtain $\tau'(y)$ we differentiate with respect to $y$ the equation
\[
T(\tau(y), D(\tau(y), y)) = 0,
\]
where $T(u, D)$ is the polynomial of Lemma 3.3. This gives a linear equation in $\tau'(y)$, from where it follows that $\tau'(1) \approx -0.21992$ and then $\rho''(1) \approx 0.44298$. Finally, the constants $\kappa$ and $\lambda$ are computed using
\[
\kappa = -\frac{\rho'(1)}{\rho(1)}, \quad \lambda = -\frac{\rho''(1)}{\rho(1)} - \frac{\rho'(1)}{\rho(1)} + \left(\frac{\rho'(1)}{\rho(1)}\right)^2.
\]
5. Outerplanar Graphs

We keep the notations of previous sections but applied to outerplanar graphs instead of series-parallel graphs. Thus \( g_n \) is the number of (labelled) outerplanar graphs on \( n \) vertices; similarly for \( c_n \) and \( b_n \), and for the corresponding generating functions. Our exposition will be brief since the necessary machinery has been introduced in the previous section and the generating functions in this case are much simpler. Moreover, we restrict our computations to the most relevant issues, namely, the asymptotic expressions for the number of outerplanar graphs, and the mean and variance of the expected number of edges in a random outerplanar graph.

As mentioned in the introduction, a 2-connected outerplanar can be seen as a dissection of a convex polygon. The ordinary GF \( A(x, y) \) for polygon dissections, where \( x \) marks vertices and \( y \) edges can be easily obtained with the method introduced in [3] for counting polygon dissections with respect to the number of faces. Indeed, let \( K \) be a convex polygon with \( n \) vertices and fix an edge \( e \) of \( K \). A dissection of \( K \) is either a single edge or an ordered sequence of \( k \geq 2 \) dissections along a face containing \( e \), where \( k - 1 \) pairs of vertices are identified. Thus we have

\[
A(x, y) = yx^2 + y \sum_{k \geq 2} \frac{A(x, y)^k}{x^{k-1}} = yx^2 + \frac{yA^2}{x - A}.
\]

The solution to the previous equation with non-negative terms is

\[
A(x, y) = \sum a_{n,k}y^kx^n = \frac{x(1 + yx - \sqrt{1 - 2y - 6y^2} + y^2x^2)}{2 + 2y}.
\]

Returning to outerplanar graphs, each dissection of \( K \) gives raise to \((n-1)!/2\) (the number of labellings of a non-oriented cycle) 2-connected outerplanar graphs, except for the special case \( n = 2 \). Hence

\[
b_{n,q} = a_{n,q}(n-1)!/2, \quad n \geq 3, \quad \text{and} \quad b_{2,1} = 1.
\]

In terms of the corresponding generating functions (recall that \( B(x, y) \) is an exponential GF), the former relations translate into

\[
B'(x, y) = \frac{1}{2}A(x, y) + yx = \frac{1 + xy(3 + 2y) - \sqrt{1 - 2xy - 4y^2 - x^2y^2}}{4(1 + y)}.
\]

For \( y = 1 \), the smallest positive root of the radicand \( 1 - 6x + x^2 \) is

\[
R = 3 - 2\sqrt{2} \approx 0.17157,
\]

which is then the radius of convergence of \( B(x) = B(x, 1) \).

Since a graph is outerplanar if and only if its connected components are outerplanar, and the blocks in the components are also outerplanar, the relations we had in the previous section between \( B, C \) and \( G \) also hold, that is

\[
G(x) = \exp(C(x)), \quad xC'(x) = x\exp(B'(xC'(x))).
\]

It follows that, for fixed \( y \), the functional inverse of \( F(x, y) = xC'(x, y) \) is

\[
\Psi_y(u) = ue^{-B'(u, y)}.
\]

Given the explicit form we have for \( B' \), it is easy to check that \( \Psi_1'(u) \) has a root \( \tau = 0.17076 \) in \([0, R]\); in fact, \( \tau \) is the smallest positive root of the equation

\[
3u^4 - 28u^3 + 70u^2 - 58u + 8 = 0.
\]
Consequently, the radius of convergence of $F(x, 1)$ and $C(x)$ is equal to
$\rho = \Psi(\tau) = 0.13659$.

**Theorem 5.1.** The number $h_n$ of outerplanar graphs is asymptotically
$$h_n \sim h \cdot n^{-5/2} \cdot \rho^{-n} n!$$
where $\rho \approx 0.13659$ and $h \approx 0.01767$.

**Proof.** The value of the dominant singularity $\rho$ has been determined previously. Since $\Psi'$ has a root in its domain of definition, the inverse function $F(x) = xC'(x)$ has a singular expansion of square-root type in $X = \sqrt{1 - x\rho}$, hence $C(x)$ has a singular expansion whose dominant term is $X^{3/2}$ and from this follows the subexponential term $n^{-5/2}$. Finally, the constant $h$ is computed as in the previous section using the evaluation of $\Psi''(\tau)$.

The proof of the next theorem is omitted, since it follows exactly the same pattern as the proof of Theorem 4.2. Computations in this case are simpler due to the explicit expression for $\Psi$.

**Theorem 5.2.** Let $X_n$ denote the number of edges in a random outerplanar graph with $n$ vertices. Then $X_n$ is asymptotically normal and the mean $\mu_n$ and variance $\sigma_n^2$ satisfy
$$\mu_n \sim \zeta n, \quad \sigma_n^2 \sim \eta n,$$
where $\zeta \approx 1.56251$ and $\eta \approx 0.22399$. The same is true, with the same constants, for connected random outerplanar graphs.

6. **The number of connected components**

In this section we determine limit laws for the number of connected components. A sequence $X_n$ of discrete random variables converges to a discrete random variable $X$ if, for every integer $k$,
$$\text{Prob}\{X_n = k\} \to \text{Prob}\{X = k\}, \quad \text{as } n \to \infty.$$In the next statement, convergence is to a *shifted* Poisson law because the number of components is always strictly positive.

**Theorem 6.1.** The distribution of the number of connected components in random series-parallel graphs is asymptotically a shifted Poisson law $1 + P(\nu)$ with parameter equal to $\nu \approx 0.11761$. The same result holds for outerplanar graphs, in this case the parameter of the Poisson law being equal to $\xi \approx 0.14840$. As a consequence the probability that a random series-parallel graph is connected tends to $e^{-\nu} \approx 0.88904$, and to $e^{-\xi} \approx 0.86208$ for outerplanar graphs.

**Proof.** We follow the same approach as the proof of Theorem 6 in [7]. We present the proof for SP graphs, the case of outerplanar graphs is analogous. For fixed $k$, the generating function of SP graphs with exactly $k$ connected components is
$$\frac{1}{k!} C(x)^k.$$For fixed $k$ we have
$$[x^k]C(x)^k \sim k C_0^{k-1} [x^n] C(x).$$
Hence the probability that a random planar SP has exactly \( k \) components is asymptotically
\[
\frac{[x^n]C(x)/k!}{[x^n]G(x)} \sim \frac{kC_0^{k-1}}{k!} e^{-C_0} = \frac{\nu^{k-1}}{(k-1)!} e^{-\nu}.
\]
If we let \( \nu = C(\rho) = C_0 \), the evaluation of \( C(x) \) at its dominant singularity, then the previous expression implies convergence to a shifted Poisson law of parameter \( \nu \). Since we know the local developments around the dominant singularity, we can compute \( C_0 \) exactly.

7. Graphs without a \( K_{2,3} \) minor

In this section we analyze briefly the class of graphs that do not contain \( K_{2,3} \) as a minor; equivalently, since \( K_{2,3} \) has maximum degree three, graphs that do not contain \( K_{2,3} \) as a subdivision. They form a class strictly larger than the class of outerplanar graphs; as we are going to see, they are not far from this class.

Let \( G \) be a 2-connected graph not containing \( K_{2,3} \) as a minor. Then either \( G \) is outerplanar (no \( K_4 \) minor) or else \( G \) contains \( K_4 \) as a minor, hence also as a subdivision. But if we subdivide just one edge of \( K_4 \), a \( K_{2,3} \) minor shows up.

Hence this subdivision can be only \( K_4 \). If \( G \) contains an additional vertex \( x \) then, by 2-connectivity there exist an edge \( yz \) of the given \( K_4 \) and two internally disjoint paths from \( x \) to \( y \) and \( z \), hence again we have a \( K_{2,3} \) minor.

In conclusion if \( G \) is 2-connected and does not contain \( K_{2,3} \) as a minor, then either \( G \) is outerplanar or \( G = K_4 \). If we apply the notation of the previous section to the new class, then the generating function \( B(x, y) \) is the same as for the class of outerplanar graphs, plus the addition of a single monomial \( y^6 x^4 / 4! \) corresponding to the exceptional graph \( K_4 \). Hence
\[
B'(x, y) = \frac{y^6 x^3}{6} + \frac{1 + xy(3 + 2y) - \sqrt{1 - 2xy - 4y^2 x + x^2 y^2}}{4(1 + y)}.
\]
From this, following the same steps as in the previous section, we obtain the following. Details are omitted in order to avoid repetition.

**Theorem 7.1.** The number \( s_n \) of graphs not containing \( K_{2,3} \) as a minor is asymptotically
\[
s_n \sim s \cdot n^{-5/2} \cdot \rho^{-n} n!.
\]
where \( \rho \approx 0.13648 \) and \( s \approx 0.013961 \).

**Theorem 7.2.** Let \( X_n \) denote the number of edges in a random graph not containing \( K_{2,3} \) as a minor with \( n \) vertices. Then \( X_n \) is asymptotically normal and the mean \( \mu_n \) and variance \( \sigma_n^2 \) satisfy
\[
\mu_n \sim \zeta n, \quad \sigma_n^2 \sim \eta n,
\]
where \( \zeta \approx 1.56325 \) and \( \eta \approx 0.224206 \). The same is true, with the same constants, for connected random graphs not containing \( K_{2,3} \) as a minor.

8. Concluding remarks

We conclude with a table showing the values of the main parameters for the classes studied in this paper, together with the class of planar graphs studied in [7]. For a given class of graphs \( G \), the growth constant \( \gamma \) is \( \rho^{-1} \), where \( \rho \) is the dominant singularity of the associated generating function \( G(x) \). In other words,
\[ \gamma = \lim_{n \to \infty} (g_n/n!)^{1/n}. \] In the last column we display the constant \( \kappa \) such that the expected number of edges is \( \sim \kappa n \).

| Class of graphs | Growth constant | Expected number of edges |
|-----------------|-----------------|-------------------------|
| Planar          | 27.2268         | 2.2132                  |
| Series parallel | 9.0733          | 1.6167                  |
| Outerplanar     | 7.3209          | 1.5625                  |
| No \( K_{2,3} \) minor | 7.3270 | 1.5632                  |
