STOCHASTIC PERTURBATIONS METHOD FOR A SYSTEM OF Riemann Invariants

OLGA S. ROZANOVA

Abstract. Basing on our results [1] on a representation of solutions to the Cauchy problem for multidimensional non-viscous Burgers equation obtained by a method of stochastic perturbation of the associated Langevin system, we deduce an explicit asymptotic formula for smooth solutions to the Cauchy problem for any genuinely nonlinear hyperbolic system of equations written in the Riemann invariants.

1. Introduction

We consider a system of the following form:

\[
\frac{\partial r_i}{\partial t} + f_i(r_1, \ldots, r_n) \frac{\partial r_i}{\partial x} = 0, \quad i = 1, \ldots, n, \tag{1}
\]

written for the functions \( r_i = r_i(t, x), \ t \in R_+, \ x \in \mathbb{R}, \) subject to initial data

\[
r(0, x) = r^0(x) = (r^0_1(x), \ldots, r^0_n(x)). \tag{2}
\]

We assume that the vector-function \( f(r) \in C^1(\mathbb{R}^n) \) is real-valued and

\[
\det \left(\frac{\partial f_j(r)}{\partial r_i}\right) \neq 0, \quad i, j = 1, \ldots, n. \tag{3}
\]

It is well known that any quasilinear hyperbolic system \( u_t + A(u)u_x = 0, \) where \( u = u(t, x) \) is a n-vector \( \mathbb{R}^2 \rightarrow \mathbb{R}^n, \) \( A(u) \) is a \((n \times n)\) matrix with smooth coefficients, can be written in the Riemann invariants if it consists of two equations. For three equations the system can be written in the Riemann invariants if only if the left eigenvectors \( l_k \) of \( A \) satisfies either \( \text{rot} \ l_k = 0 \) or \( l_k \cdot \text{rot} \ l_k = 0 \) [3]. Among physically meaningful systems admitting the Riemann invariants one can name the equations of isentropic gas dynamics, equations of shallow water, equations of electrophoresis and equations of chromatography [8], [10], [4].

2. Extended system and stochastic differential equation associated with the equations of characteristics

Basing on [4] we consider a system

\[
\frac{\partial q_k}{\partial t} + f_k(q_1, \ldots, q_n) \frac{\partial q_k}{\partial x_k} = 0, \quad k = 1, \ldots, n, \tag{4}
\]

written for functions \( q_k(t, x), \ x \in \mathbb{R}^n, \) together with initial data

\[
q(0, x) = q^0(x) = (q^0_1(x), \ldots, q^0_n(x)). \tag{5}
\]

Key words and phrases. Riemann invariants, stochastic perturbation, the Cauchy problem, representation of solution, associated conservation laws.
Let us suppose that \( x_i, i = 1, \ldots, n \), are in its turn functions of one variable \( \bar{x} \in \mathbb{R} \). In this case the system (4) should be rewritten as

\[
\frac{\partial q_i}{\partial t} + f_i(q_1, \ldots, q_n) \frac{\partial q_i}{\partial x_i}(\bar{x}) = 0, \quad k, i = 1, \ldots, n,
\]

(6)

It can be readily checked that if we set

\[
q_i(t, 0, \ldots, \bar{x}, \ldots, 0) := r_i(t, \bar{x}),
\]

(7)

such that \( \frac{\partial q_i}{\partial x_m} = 0, i \neq m \), and

\[
q_i^0(0, \ldots, \bar{x}, \ldots, 0) := r_i^0(\bar{x}),
\]

(8)

\( i, m = 1, \ldots, n \), then the vector-function \( r(t, \bar{x}) \) solve the problem (11), (12).

We associate with (4) the following system of stochastic differential equations:

\[
dX_i(t) = f_i(Q_1(t), \ldots, Q_n(t))dt + \sigma_1 dW_i^1(t),
\]

\[
dQ_i(t) = \sigma_2 dW_i^2(t), \quad i = 1, \ldots, n,
\]

(9)

\[
X_i(0) = x_i, \quad Q_i(0) = q_i, \quad t > 0,
\]

where \( X(t) \) and \( Q(t) \) - are random values with given initial data, \( (X(t), Q(t)) \) takes values in the phase space \( \mathbb{R}^n \times \mathbb{R}^n \), \( \sigma_1 \) and \( \sigma_2 \) - are positive constants, \( |\sigma| \neq 0 \) (\( \sigma = (\sigma_1, \sigma_2) \)), \( (W^j)_t = (W^j_1, \ldots, W^j_n)_t \), \( j = 1, 2 \), are independent Brawnian motions.

Let \( P(t, dq_1, \ldots, dq_n, dx_1, \ldots, dx_n) \), \( t \in \mathbb{R}_+, x_i \in \mathbb{R}, q_i \in \mathbb{R}, i = 1, \ldots, n \), be the joint probability distribution of the random variables \( (Q, X) \), subject to the initial data

\[
P_0(dr, dx) = \prod_{i=1}^n \delta_q(q^0_i(x_i)) \rho^0_i(x_i) dx = \delta_q(q^0(s)) \rho^0(s),
\]

(10)

where \( \rho^0_i(x_i) \) are bounded nonnegative functions from \( C(\mathbb{R}) \) and \( dx \) is Lebesgue measure on \( \mathbb{R}^n \), \( \delta_q \) is Dirac measure concentrated on \( q \).

We look at \( P = P(t, dq, dx) \) as a generalized function (distribution) with respect to the variable \( q \). It satisfies the Fokker-Planck equation

\[
P_t + \sum_{i=1}^n f_i(q)P_{x_i} = \frac{\sigma^2}{2} \sum_{i=1}^n P_{x_i x_i} + \frac{\sigma^2}{2} \sum_{i=1}^n P_{q_i q_i},
\]

(11)

with initial data (10).

There is a standard procedure for finding the fundamental solution for (11) (see, e.g. [5]). This procedure consists in a reduction of the equation to a Fredholm integral equation, the solution of which can be found in the form of series. We are going to show that one can also find an explicit solution to the Cauchy problem (11), (10).

Let us introduce, still in the general case, the functions, for \( t \in \mathbb{R}_+, x \in \mathbb{R}^n \), depending on \( \sigma = (\sigma_1, \sigma_2) \):

\[
\rho_{i, \sigma}(t, x_i) = \int_{\mathbb{R}^{2n-1}} P(t, x, dr) d\bar{x}_i,
\]

(12)
STOCHASTIC PERTURBATIONS METHOD FOR A SYSTEM OF RIEMANN INVARIANTS

\[ \rho_{\sigma}(t, x) = \int_{\mathbb{R}^n} P(t, x, dq), \]

(13)

\[ q_{i,\sigma}(t, x) = \int_{\mathbb{R}^n} q_i P(t, x, dq) \int_{\mathbb{R}^n} P(t, x, dq), \]

(14)

\[ f_{i,\sigma}(t, x) = \int_{\mathbb{R}^n} f_i(q) P(t, x, dq) \int_{\mathbb{R}^n} P(t, x, dq), \]

(15)

where

\[ d\bar{x}_i = dx_1 .. dx_{i-1} dx_{i+1} .. dx_n, \quad dr = dr_1 .. dr_n. \]

We can consider these values if the integrals exist in the Lebesgue sense.

It will readily be observed that \( q_{i,\sigma}(0, x) = q^0_i(x) \) and \( f_{i,\sigma}(0, x) = f(q^0_i(x)) \).

We denote

\[ \bar{\rho}_i(t, \bar{x}) = \lim_{\sigma \to 0} \rho_{i,\sigma}(t, \bar{x}), \quad \bar{\rho}(t, x) = \lim_{\sigma \to 0} \rho_{\sigma}(t, x), \]

\[ \bar{q}_{i,\sigma}(t, x) = \lim_{\sigma \to 0} q_{i,\sigma}(t, x), \quad \bar{f}_i(t, x) = \lim_{\sigma \to 0} f_{i,\sigma}(t, x), \]

provided these limits exist, \( \sigma = \sqrt{\sigma_1^2 + \sigma_2^2} \).

3. Explicit probability density function

The equation (11) can be solved explicitly. Moreover, for the sake of simplicity we set \( \sigma_2 = 0 \) and denote \( \sigma_1 = \sigma \).

**Proposition 3.1.** The problem (11), (10) has the following solution:

\[ P(t, x, dq) = \]

\[ \frac{1}{(\sqrt{2\pi\sigma})^n} \int_{\mathbb{R}^n} \delta_r(r^0(s)) \rho^0(s) \exp \left( -\frac{\sum_{i=1}^n (f_i(r^0_1(s_1), ..., r^0_n(s_n)) t + (s_i - x_i))^2}{2\sigma^2 t} \right) ds, \]

for \( t \geq 0, x \in \mathbb{R}^n \), therefore

\[ \int_{\mathbb{R}^n} \phi(q) P(t, x, dq) = \]

\[ = \frac{1}{(\sqrt{2\pi\sigma})^n} \int_{\mathbb{R}^n} \phi(r^0(s)) \rho^0(s) \exp \left( -\frac{\sum_{i=1}^n (f_i(r^0_1(s_1), ..., r^0_n(s_n)) t + (s_i - x_i))^2}{2\sigma^2 t} \right) ds, \]

for all \( \phi(r) \in C_0(\mathbb{R}^n) \).

**Proof.** Let us apply the Fourier transform to \( P(t, x, dq) \) in (11), (10) with respect to the variable \( x \) and obtain the Cauchy problem for the Fourier transform \( \tilde{P} = \tilde{P}(t, \lambda, dq) \) of \( P(t, x, dq) \):

\[ \frac{\partial \tilde{P}}{\partial t} = -\frac{1}{2} \sigma^2 |\lambda|^2 + i(\lambda, f(q))\tilde{P}, \]

(18)
Equation (18) can easily be integrated and we obtain the solution given by the following formula:

\[
P(t, \lambda, dq) = \hat{P}(0, \lambda, dq) e^{-\frac{1}{2} \sigma^2 |\lambda|^2 + i \lambda f(q)} t.
\]

The inverse Fourier transform (in the distributional sense) allows to find the density function \(P(t, x, dq)\), \(t > 0\):

\[
P(t, x, dq) = \frac{1}{(2\pi)^n} \int \hat{P}(t, \lambda, dq) d\lambda =
\]

\[
= \frac{1}{(2\pi)^n} \int e^{i(\lambda, x)} \left( \int e^{-i(\lambda, s)} e^{-i(\lambda, f(q)) t} \delta_q(q^0(s)) \rho^0(s) ds \right) e^{-\frac{1}{2} \sigma^2 |\lambda|^2 t} d\lambda =
\]

\[
= \frac{1}{(2\pi)^n} \int \delta_q(q^0(s)) \rho^0(s) \int e^{-\frac{1}{2} \sigma^2 t \left( \lambda - \frac{f(q) + x - x_i}{\sigma} \right)^2 - \frac{(q^0(s) + x - x_i)^2}{2\sigma^2}} d\lambda ds =
\]

\[
= \frac{1}{(\sqrt{2\pi}\sigma)^n} \int \delta_q(q^0(s)) \rho^0(s) e^{-\frac{(q^0(s) + x - x_i)^2}{2\sigma^2}} ds, \quad t \geq 0, \; x \in \mathbb{R}^n.
\]

The third equality is satisfied by Fubini’s theorem, which can be applied by the absolute integrability and the bound on the function involved. Thus, the proposition is proved. \(\square\)

**Remark 3.1.** In the general case \(\sigma_2 \neq 0\) an analogous formula can be obtained in a similar way (see [6] in this context).

**Corollary 3.1.** The functions \(\rho_{\sigma}\), \(q_{\sigma}\) and \(f_{\sigma}\) defined in (13) - (15) can be represented by the following formulae:

\[
\rho_{\sigma}(t, x) = \frac{1}{(\sqrt{2\pi}\sigma)^n} \int_{\mathbb{R}^n} \rho^0(s) e^{-\frac{\sum_{i=1}^{n} |f_i(r^0(s)) + x_i - x_j|^2}{2\sigma^2}} ds,
\]

\[
q_{\sigma,i}(t, x) = \int_{\mathbb{R}^n} r^0(s) \rho^0(s) e^{-\frac{\sum_{i=1}^{n} |f_i(r^0(s)) + x_i - x_j|^2}{2\sigma^2}} ds, \quad i = 1, \ldots, n,
\]

\[
f_{\sigma,i}(t, x) = \int_{\mathbb{R}^n} f(r^0(s)) \rho^0(s) e^{-\frac{\sum_{i=1}^{n} |f_i(r^0(s)) + x_i - x_j|^2}{2\sigma^2}} ds, \quad i = 1, \ldots, n.
\]

**Proof.** The result is obtained by substitution of \(P(t, x, dq)\) as given by (16) in (13), (14), (15). \(\square\)
4. Representation of smooth solution to (1), (2)

Now we are going to prove that if $\rho_i$ and $\bar{q}_i$ are continuous, then $\bar{r}_i(x) = \bar{q}_i(t, x)|_{x_j=0, x_i=x_i}$, $j \neq i$, tend to the solution $r_i(x)$ of the problem (1), (2) as $\sigma \to 0$.

Namely, the following theorem holds.

**Theorem 4.1.** Let $r(t, x)$ be a solution to the Cauchy problem (1), (2), $r^0 \in C^1_b(\mathbb{R})$ and $t^\ast(r^0)$ be the supremum of $t$ such that this solution is smooth. Then for $t \in [0, t^\ast(r^0))$,

$$r_i(t, x) = \bar{q}_i(t, x)|_{x_j=0, x_i=x_i} = \lim_{\sigma \to 0} q_{\sigma, i}(t, x)|_{x_j=0, x_i=x_i}, \ j \neq i,$$

where $q_{\sigma}(t, x)$ is given by (23) and the limit exists pointwise.

**Proof.** The easiest way to prove the theorem is reducing of (4) to the multidimensional non-viscous Burgers equation and using the representation from [1]. Namely, (4) has the form

$$\partial_t q + (f(q), \nabla) q = 0,$$

where $q(t, x) = (q_1, ..., q_n)$ is a vector-function $\mathbb{R}^{n+1} \to \mathbb{R}^n$, $f(q)$ is a non-degenerate differential mapping from $\mathbb{R}^n$ to $\mathbb{R}^n$, such that its Jacobian satisfies the condition $\det \frac{\partial f(q)}{\partial q} \neq 0$, $i, j = 1, ..., n$, due to (3).

We multiply (24) by $\nabla f_i(q)$, $i = 1, ..., n$, to get

$$\partial_t f(q) + (f(q), \nabla) f(q) = 0.$$  

Thus, we can introduce a new vectorial variable $u = f(q)$ to reduce the Cauchy problem for (26) to

$$\partial_t u + (u, \nabla) u = 0, \quad t > 0, \quad u(x, 0) = u_0(x) \in C^1(\mathbb{R}^n) \cap C_b(\mathbb{R}^n).$$

with $u_0(x) = f(q_0(x))$. As follows from [1], the solution to the nonviscous Burgers equation (26) before the moment $t^\ast$ of a singularity formation can be obtained as a pointwise limit as $\sigma \to 0$ of

$$u_{\sigma}(t, x) = \frac{\int_{\mathbb{R}^n} u_0(s) \rho^0(s) e^{-\frac{|u_0(s) + u - x|^2}{2\sigma^2}} ds}{\int_{\mathbb{R}^n} \rho^0(s) e^{-\frac{|u_0(s) + u - x|^2}{2\sigma^2}} ds},$$

where $\rho^0(s)$ is a non-negative function.

Therefore we find the representation of the solution to the stochastically perturbed along the characteristics equation (26) using the formula (27) with $f(q_0(x))$ instead of $u_0(x)$.

Now we can go back to the vector-function $q(t, x)$. As follows from Proposition 3.1, $\bar{q}_i(t, x) = \lim_{\sigma \to 0} q_{\sigma, i}(t, x)$. At last, we use the redesignation (7) to obtain the statement of theorem 4.1.

Further, we can find the maximal time $t^\ast(r^0)$ of existence of the smooth solution to the problem (1), (2).

**Theorem 4.2.** If at least one derivative

$$\frac{\partial f_i(q)}{\partial q_i} \frac{d\rho_i^0(x)}{dx}, \quad i = 1, ..., n,$$

where $\rho_1^0(x)$ is a non-negative function.
is negative, then the time \( t_*(r^0) \) of existence of the smooth solution to (1), (2) is finite and
\[
t_*(r^*) = \min_i \left\{ - \left( \frac{\partial f_i(q)}{\partial q_i} \frac{dx_i^0(x)}{dx} \right)^{-1} \right\}.
\] (29)
Otherwise, \( t_*(r^0) = \infty \).

Proof. Let us come back to the problem (26) and denote by \( J(u_0(x)) \) the Jacobian matrix of the map \( x \mapsto u_0(x) \). As it was shown in [7] (Theorem 1), if \( J(u_0(x)) \) has at least one eigenvalue which is negative for a certain point \( x \in \mathbb{R}^n \), then the classical solution to (26) fails to exist beyond a positive time \( t_*(u_0) \). Otherwise, \( t_*(u_0) = \infty \). The matrix \( C(t, x) = (I + tJ(u_0(x))) \), where \( I \) is the identity matrix, fails to be invertible for \( t = t_*(u_0) \). Thus, due to representation (25), if \( J(f(q_0(x))) \) has at least one eigenvalue which is negative for a certain point \( x \in \mathbb{R}^n \), then the classical solution to (1) fails to exist beyond a positive time \( t_*(q_0) \). For the problem (1), (2) this means that at least one derivative (28) is negative. The value (29) can be found from the condition of invertibility of the matrix \( (I + tJ(f(q_0(x))) \). ∎

Remark 4.1. It easy to see that Theorem 4.2 can be considered as a version of Theorem 7.8.2 [4], with a specification of the blow up time, obtained by a different method.

5. Balance laws, associated with systems written in the Riemann invariants

Now we get one more corollary of results of [1]. Let us denote
\[
g_{i,\sigma}(t, \bar{x}) = f_{i,\sigma}(t, x) \big|_{(x_j=0, x_i=\bar{x})}, \quad \bar{g}_i(t, \bar{x}) = \lim_{\sigma \to 0} g_{i,\sigma}(t, \bar{x}).
\]

Theorem 5.1. The functions \( \rho_{i,\sigma} \) and \( g_{i,\sigma} \) satisfy the following system of 2n equations:
\[
\frac{\partial \rho_{i,\sigma}}{\partial t} + \frac{\partial x}{\partial \rho_{i,\sigma} g_{i,\sigma}} = \frac{1}{2} \sigma^2 \frac{\partial^2 \rho_{i,\sigma}}{\partial x^2},
\] (30)
\[
\frac{\partial (\rho_{i,\sigma} g_{i,\sigma})}{\partial t} + \frac{\partial x}{\partial (\rho_{i,\sigma} g_{i,\sigma})} = \frac{1}{2} \sigma^2 \frac{\partial^2 (\rho_{i,\sigma} g_{i,\sigma})}{\partial x^2} - \int_{\mathbb{R}^{2n-1}} (g_{\sigma,i} - \bar{g}(r)) \left( (g_{\sigma} - \bar{g}(r)) , \nabla_x P(t, x, dq) \right) dx.
\] (31)

For \( t \in (0, t_*(r^0)) \) its limit functions \( \bar{\rho}_i \) and \( \bar{g}_i \) satisfy the system of 2n conservation laws:
\[
\frac{\partial \bar{\rho}_i}{\partial t} + \frac{\partial x}{\partial \bar{\rho}_i \bar{g}_i} = 0,
\] (32)
\[
\frac{\partial (\bar{\rho}_i \bar{g}_i)}{\partial t} + \frac{\partial x}{\partial (\bar{\rho}_i \bar{g}_i)} = 0,
\] (33)
i = 1, ..., n, \( t \geq 0 \).

Proof. The statement follows from Theorem 2.1 [11]. Namely, the theorem implies that the scalar function \( \rho_{\sigma} f_\sigma(t, x) \) and the vector-function \( f_\sigma(t, x) \) solve the following system:
\[
\frac{\partial \rho_{\sigma}}{\partial t} + \text{div}_x (\rho_{\sigma} f_\sigma) = \frac{1}{2} \sigma^2 \sum_{k=1}^{n} \frac{\partial^2 \rho_{\sigma}}{\partial x_k^2},
\] (34)
\[
\frac{\partial (\rho\sigma f_i,\sigma)}{\partial t} + \nabla (\rho\sigma f_i f_\sigma) = \frac{1}{2}\sigma^2 \sum_{k=1}^{n} \frac{\partial^2 (\rho f_{\sigma i})}{\partial x_k^2} - \int_{\mathbb{R}^n} (f_i,\sigma - \bar{f}_i) (f_\sigma - \bar{f}), \nabla x P(t, x, dq),
\]
with \(i = 1, \ldots, n, t \geq 0\), and the integral term vanishes as \(\sigma \to 0\). To obtain the statement of Theorem 5.1 it is sufficient to set \(x_j = 0, x_i = \bar{x}\) and \(\rho_j(x_j) = 1, j \neq i\), for every fixed \(i\).

**Remark 5.1.** System (32), (33) constitutes \(n\) systems of so called “pressureless” gas dynamics, the simplest model introduced to describe the formation of large structures in the Universe, see, e.g. [9].

**Remark 5.2.** The method of stochastic perturbations allows to study solutions to quasilinear systems written in Riemann invariants at the moment of the singularity formation and the shock waves evolution as well (see in this context [2], [1], [6] for simpler cases). In particular, it is possible to prove that after the moment \(t^*_r(r^0)\) of singularity formation in the solution to the problem (1), (2) the limit system for \(\rho_{i,\sigma}\) and \(g_{i,\sigma}\) differs from (32), (33) and contains an additional integral term in the group of equations (33). This term does not vanish as \(\sigma \to 0\) and can be considered as gradient of a specific pressure term.
