Abstract. We describe a study motivated by our interest to examine the incompleteness of the Ehrenfest’s theorem in quantum mechanics and to resolve a doubt regarding whether or not the hermiticity of the hamiltonian operator is sufficient to justify a simplification of the expression of the macroscopic-observable time derivative that promotes the one usually found in quantum-mechanics textbooks. The study develops by considering the simple quantum system “particle in one-dimensional box”. We propose theoretical arguments to support the incompleteness of the Ehrenfest’s theorem in the formulation he gave, in agreement with similar findings already published by a few authors, and corroborate them with the numerical example of an electric charge in an electrostatic field. The contents of this study should be useful to Bachelor and Master students; the style of the discussions is tailored to stimulate, we hope, the student’s ability for independent thinking.

1. Introduction

In a short communication [1] published in 1927, Ehrenfest showed that the macroscopic observables (also mean values or expectations values of) position ⟨x⟩ and momentum ⟨p⟩ of a point particle of mass m are governed by Newtonian equations of motion [Eqs. (4) and (5) at page 456] under the action of the force

\[ \int dx \Psi \Psi^\dagger \left( -\frac{\partial V}{\partial x} \right) \]  

(1)
On Ehrenfest’s theorem

imputable to the physical potential $V(x)$. He began from the time-dependent Schrödinger equation and its complex conjugate but did not give specific details about the proof; he just mentioned generic substitutions and integration by parts, and stressed that no neglect (ohne Vernachlässigung) was needed. One year later, in 1928, Ruark [2] extended Ehrenfest’s theorem to a conservative system containing any number of particles. The force on the generic particle, analog to Eq. (1), in Ruark’s procedure appeared accompanied by an additional term (equation at bottom of page 537) that was promptly dismissed by a synthetic declaration about its vanishing after integration by parts and subsequent application of Green’s theorem; also Ruark did not give more specific details of his proof. Ehrenfest’s theorem is duly reported in quantum-mechanics textbooks [3–8] and it has been positively valued by some authors [9, 10] but scrutinised with critical eye by other authors [11–16]. Assuming, for the time being, the correctness of the theorem in the form

$$\frac{d\langle x \rangle}{dt} = \frac{1}{m} \langle p \rangle$$

$$\frac{d\langle p \rangle}{dt} = \int \Psi^* \left( -\frac{\partial V}{\partial x} \right) \Psi dx,$$

the first aspect of Eqs. (2) targeted by criticism is the interpretation that they constitute Newtonian laws of motion. Wheeler [12] stressed vehemently the lack of rigour of such interpretation by pointing out that the equivalence

$$\int \Psi^* \left( -\frac{\partial V}{\partial x} \right) \Psi dx = - \left[ \frac{\partial V}{\partial x} \right]_{x=\langle x \rangle}$$

necessary to give full physical meaning to the interpretation in question holds only under specific cases, the most renown of which is the harmonic oscillator. In general, Eq. (3) does not hold and the above set of differential equations [Eqs. (2)] is not in closed form from a mathematical point of view; a convincing example is provided by the one-dimensional Coulomb potential $V(x) \sim 1/x$. Also Messiah [3], Jammer [17] and Ballentine [6] unambiguously pointed out the inappropriateness of the idea that the macroscopic observables $\langle x \rangle$ and $\langle p \rangle$ follow the laws of classical mechanics; moreover, Ballentine et al [18] pushed the criticism even further despite the applicability of Eq. (3). Shankar [19] studied the equivalence of Eq. (2b) with its classical-mechanics counterpart by carrying out an interesting analysis based on the concept of fluctuations and concluded by pointing out very clearly the quantitative limits of such an equivalence interpretation. Well, these critiques can be hardly argued against but, to some extent, they are mild. Another criticism that, in our opinion, strikes harder and deeper is the one that questions the completeness of Eqs. (2); indeed, Hill [11], Alonso et al [13, 14] and De Vincenzo [15, 16] detected additional terms appearing on their right-hand sides.

The purpose of our study is the investigation of this incompleteness matter parallel to the conceptual pathways traced by Hill, Alonso et al, and De Vincenzo by bringing forth and elaborating on aspects that, to the best of our knowledge, do not seem to
have been considered before. We are going to look at the way boundary conditions are involved with respect to operator hermiticity, macroscopic-observable time derivative, and consequences on the Ehrenfest theorem, which is usually stated implicitly with the infinite-space physical domain in mind. The effect of three kinds of boundary conditions on the way that the theorem should be stated are considered and, for one of those kinds, we will corroborate the theoretical analysis with a significant numerical example.

Before launching ourselves onto the analysis’ intricacies however, we find in order here to state clearly the following remark: systematic exposition and discussion regarding the physical meaning of boundary conditions in quantum mechanics with respect to the generality of the subject matter is in no way meant to be the central theme of this work. Good discussions about that theme were provided, for example, by Peierls [20], Cassels [21] and Reif [22], although they did not specifically discuss boundary conditions in connection with Ehrenfest’s theorem.

2. Macroscopic-observable time derivative and hermiticity

The Ehrenfest’s theorem surfaces in connection with the time derivative of the generic macroscopic observable \( \langle \Omega \rangle \) associated with an operator \( \Omega \) and generally defined [7] as

\[
\langle \Omega \rangle \cdot \int \Psi^* \Psi \, d\tau = \int \Psi^* \Omega \Psi \, d\tau
\]

In Eq. (4), \( \tau \) is the spatial domain spanned by the coordinates required by the quantum system under consideration. If it is possible to normalise the wavefunction

\[
\int \Psi^* \Psi \, d\tau = 1
\]

then Eq. (4) reduces to the standard form

\[
\langle \Omega \rangle = \int \Psi^* \Omega \Psi \, d\tau
\]

A simple time-differentiation exercise [5, 7, 8] that starts from Eq. (6) and takes advantage of the Schrödinger equation

\[
i \hbar \frac{\partial \Psi}{\partial t} = H \Psi
\]

and its complex conjugate provides the expression

\[
\frac{d\langle \Omega \rangle}{dt} = \frac{i}{\hbar} \int [ (H \Psi)^* (\Omega \Psi) - \Psi^* H (\Omega \Psi) ] \, d\tau + \frac{i}{\hbar} \int \Psi^* [H, \Omega] \Psi \, d\tau + \int \Psi^* \frac{\partial \Omega}{\partial t} \Psi \, d\tau
\]
on the basis of the claimed hermiticity of the hamiltonian operator. The Ehrenfest’s
theorem in the form of Eqs. (2) springs from the simplified Eq. (8)
\[
\frac{d\langle \Omega \rangle}{dt} = \frac{i}{\hbar} \int \Psi^* \{H, \Omega\} \Psi \, d\tau + \int \Psi^* \frac{\partial \Omega}{\partial t} \Psi \, d\tau
\]
when it is particularised to position and momentum operators and after specification of
the hamiltonian operator. Equation (10) is also evoked [3, 7, 8] as supporting proof of
the seemingly obvious statement of conservation: the macroscopic observable of a time-

dependent operator \( \partial \Omega / \partial t = 0 \) that commutes with the hamiltonian \([H, \Omega] = 0\) does
not change with time and is, therefore, conserved.

Hermiticity is an extremely important feature in quantum mechanics because
it ensures real values of the macroscopic observables and, thus, confers physical
significance to them; a complex-valued macroscopic observable would not make sense
from a physical point of view [5, 7, 8, 23]. Such a lucid motivation for hermiticity is
hardly disputable. But, in general, hermiticity comes with a fee. Let us consider the
energy operator
\[
\Omega = E = i \hbar \frac{\partial}{\partial t}
\]
for example; according to the general definition [Eq. (4)], the corresponding
macroscopic observable is
\[
\langle E \rangle \cdot \int \Psi^* \Psi \, d\tau = \int \Psi^* i \hbar \frac{\partial \Psi}{\partial t} \, d\tau
\]
and its complex conjugate reads
\[
\langle E^* \rangle \cdot \int \Psi \Psi^* \, d\tau = -\int \Psi^* i \hbar \frac{\partial \Psi^*}{\partial t} \, d\tau
\]
Subtraction of Eq. (13) from Eq. (12) yields
\[
\langle E \rangle - \langle E^* \rangle = i \hbar \frac{d}{dt} \left[ \ln \left( \int \Psi^* \Psi \, d\tau \right) \right]
\]
Equation (14) indicates that the fee for the hermiticity of the energy operator is the
normalisation [Eq. (5)] of the wavefunction; as a matter of fact, any arbitrary constant
on the right-hand side of Eq. (5) would do but we can always scale the wavefunction
in Eq. (7) so that the constant becomes equal to 1. Thus, normalisation comes more
as an obligation rather than a choice; we must be able to coerce the wavefunction into
compliance with Eq. (5) in order to expect real values of the macroscopically observable
energy
\[
\langle E \rangle = \langle E^* \rangle
\]
If one day we confront a problem within which we are not able to normalise the
wavefunction then Eq. (15) breaks down and we should really ponder carefully about
what physical meaning the problem we are dealing with has [5, 8, 23]. Hereinafter, we
assume the validity of Eq. (5).
Let us consider the hamiltonian operator now. From the Schrödinger equation [Eq. (7)] and Eq. (12) we obtain

$$\langle H \rangle = \langle E \rangle$$

from which we deduce that also the hamiltonian must be hermitean

$$\langle H \rangle - \langle H \rangle = \int [ (H\Psi)^* \Psi - \Psi^* H \Psi ] \, d\tau = 0$$

(17)

From our point of view, we look at Eq. (17) not as a warranty of but rather as a test for hermiticity; in other words, when we are given an explicit hamiltonian then we should subject it to Eq. (17) to find out whether or not it can be certified as hermitean. It is rather straightforward to anticipate that the execution of such a test will bring forth the boundary conditions involving wavefunction and its derivatives and that they will play a fundamental role for the positive outcome of the test.

Let us assume that the test is passed and the hamiltonian is indeed hermitean. If we compare the integrals of Eqs. (9) and (17) we notice that the latter’s integrand involves only the wavefunction and its complex conjugate while the former’s integrand involves also the action of the operator $\Omega$ on the wavefunction. Therefore, we may legitimately ask: is the hermiticity of the hamiltonian sufficient to make the integral $I_\Omega$ [Eq. (9)] vanish regardless of which operator $\Omega$ intervenes in it? Usually, quantum-mechanics textbooks [5, 7, 8] give a decidedly affirmative answer: if the integral $I_\Omega$ vanishes for the unitary operator $\Omega = 1$, and therefore the hamiltonian is hermitean, then it vanishes for any other operator $\Omega$. Proofs are provided, of course, but their weaknesses have been nailed down, for example, by Alonso et al [13, 14] and De Vincenzo [15, 16] whose analyses take advantage of refined quantum-mechanical terminology, concepts and notation. Here, however, we take the humbler attitude of the student with a scientifically curious (or maybe skeptical) mind who does not master yet the level of quantum-mechanical sophistication of the analyses mentioned a few lines ago and, leaning on her/his skill with integral calculus, may decide to find out the answer by going through the direct execution of the integral $I_\Omega$; after all, carrying on along that course does not seem a terribly difficult task to accomplish with an explicitly declared and simple hamiltonian. This is exactly what we plan to do in the next sections by considering the typical simple quantum system “particle in one-dimensional box”. In passing, before concluding this section, we wish to point out that the doubt injected by the question about the hamiltonian-hermiticity sufficiency to dismiss the integral $I_\Omega$ imperils also the conservation statement mentioned in connection with Eq. (10).

### 3. Particle in one-dimensional box

#### 3.1. Preliminary considerations

The particle lives on the $x$ axis and is subjected to the physical potential $V(x)$. The spatial domain of interest is the segment $[-L, +L]$ and all the integrals in Sec. 2 become
On Ehrenfest’s theorem

One-dimensional

\[ \int (\cdots) \, d\tau \rightarrow \int_{-L}^{+L} (\cdots) \, dx \]  

(18)

The particle’s Hamiltonian is simply

\[ H = -\frac{\hbar^2}{2m} \frac{\partial^2}{\partial x^2} + V(x) \]  

(19)

Hereinafter, we reserve the term Hamiltonian exclusively to indicate Eq. (19). The quantum mechanics of the particle is governed by the Schrödinger equation

\[ i\hbar \frac{\partial \Psi}{\partial t} = -\frac{\hbar^2}{2m} \frac{\partial^2 \Psi}{\partial x^2} + V \Psi \]  

(20)

whose integration calls for an initial condition

\[ \Psi(x, 0) = f(x) \]  

(21)

and appropriate boundary conditions. We consider three sets of wavefunction boundary conditions

\[
\begin{aligned}
&\Psi(-L, t) = \Psi(+L, t) = 0 \quad \text{(c)} \\
&\Psi(-L, t) = \Psi(+L, t) \quad ; \quad \left( \frac{\partial \Psi}{\partial x} \right)_{x=-L} = \left( \frac{\partial \Psi}{\partial x} \right)_{x=+L} \quad \text{(p)} \\
&\left( \frac{\partial \Psi}{\partial x} \right)_{x=-L} = \left( \frac{\partial \Psi}{\partial x} \right)_{x=+L} = 0 \quad \text{(v)}
\end{aligned}
\]

(22)

Initially confinement [Eq. (22)(c)] attracted our main interest from a physical point of view but then, after becoming familiar with the papers of Hill [11] and Alonso et al [13, 14], we decided to incorporate in the investigation also periodicity [Eq. (22)(p)] and vanishing-derivative [Eq. (22)(v)] conditions in order to find out if we could retrieve the results already obtained by the mentioned authors. We understand that the possibility to impose the periodic boundary conditions implies, or better is a consequence of, the periodicity of the potential

\[ V(+L) = V(-L) \]  

(23)

As it is well known, the general solution of Eq. (20) can be cast in the form of a series expansion

\[ \Psi(x, t) = \sum_r c_r \cdot \exp \left( -i \frac{\varepsilon_r t}{\hbar} \right) \psi_r(x) \]  

(24)

whose coefficients are established by the initial wavefunction

\[ c_r = \int_{-L}^{+L} \psi_r(x) f(x) \, dx \]  

(25)
In Eq. (24), \( \varepsilon_r \) and \( \psi_r \) are eigenvalues and eigenfunctions of the time-independent Schrödinger equation

\[
H\psi = -\frac{\hbar^2}{2m} \frac{\partial^2 \psi}{\partial x^2} + V\psi = \varepsilon \psi
\]  

which must be integrated with the eigenfunction boundary conditions

\[
\begin{align*}
\psi(-L) &= \psi(+L) = 0 \\
\psi(-L) &= \psi(+L) ; \quad \left( \frac{\partial \psi}{\partial x} \right)_{x=-L} &= \left( \frac{\partial \psi}{\partial x} \right)_{x=+L} \\
\left( \frac{\partial \psi}{\partial x} \right)_{x=-L} &= \left( \frac{\partial \psi}{\partial x} \right)_{x=+L} = 0
\end{align*}
\]  

in obvious compliance with the selection [Eqs. (22)] to be satisfied by the wavefunction.

### 3.2. Hermiticity test for the Hamiltonian

The execution of the test requires the substitution of the Hamiltonian in Eq. (17) and the subsequent the integration; this series of operations leads to the following expression

\[
\langle H \rangle^* - \langle H \rangle = \frac{\hbar^2}{2m} \left[ \left( \psi \frac{\partial \psi}{\partial x} - \psi \frac{\partial \psi}{\partial x} \right)_{x=+L} - \left( \psi \frac{\partial \psi}{\partial x} - \psi \frac{\partial \psi}{\partial x} \right)_{x=-L} \right]
\]  

which is in accordance with (and, to some extent, even more formally consistent of) Eq. (4.3) at page 19 of Cassels’ textbook [21]. Equation (28) shows explicitly how certification for hermiticity goes through the wavefunction boundary conditions. As far as our Hamiltonian is concerned, we are on safe ground with the sets we are considering because the right-hand side of Eq. (28) vanishes identically

\[
\langle H \rangle^* - \langle H \rangle = 0
\]  

with each one of Eqs. (22) but such an occurrence should not give us a false sense of conviction that positive hermiticity certification is necessarily going to happen with other operators. For example, the momentum operator

\[
p = \frac{\hbar \partial}{i \partial x}
\]  

is not so lucky

\[
\langle p \rangle^* - \langle p \rangle = -\int_{-L}^{+L} \psi \frac{\hbar \partial \psi}{i \partial x} \, dx - \int_{-L}^{+L} \psi \frac{\hbar \partial \psi}{i \partial x} \, dx = i \hbar \left[ (\psi \psi')_{x=+L} - (\psi \psi')_{x=-L} \right]
\]  

Equation (31) is a more formally consistent version of the analogous Eq. (4.2) provided by Cassels at page 19 of his textbook [21]. The rightmost-hand side of Eq. (31) survives, in general, with the vanishing-derivative boundary conditions and therefore
the momentum operator is not hermitean in the (v) case. Such a state of affairs casts obvious doubts about the physical meaning of imposing vanishing wavefunction’s derivatives at the boundaries. However, here we wish only to raise a warning flag but we will not go down that conceptual road any further because its ramifications deviate substantially from the main stream of our investigation’s theme, as we have already pointed out clearly at the end of Sec. 1; Alonso et al [13, 14] and De Vincenzo [16] provide good entry points to that conceptual road for the reader interested in pursuing the matter further. Nevertheless, doubts notwithstanding, we do not consider the physical-meaning fragility of the (v) case an impelling reason for dismissal from our investigation yet; on the contrary, we believe that, at least for the time being, the (v) case contains an added pedagogical value because it exposes the student to an outstanding example that teaches an important lesson, to keep always in mind, about a recurring luring trap (particularly in quantum mechanics): even if the mathematics required by a physical problem flows smoothly, works finely (as we soon will see) and, in so doing, leaves us with an ecstatic sensation of respectful wonder, that is still insufficient warrant to confer physical solidity to results and conclusions.

Coming back to the hamiltonian, we can go one level deeper than Eq. (28) if we insert the wavefunction general solution in Eq. (17) but hang on with the replacement of the hamiltonian; if we do so, we obtain

\[
\langle H \rangle - \langle H \rangle = \sum_{r,s} c_r c_s^* \exp \left( \frac{i \epsilon_r - \epsilon_s}{\hbar} t \right) \int_{-L}^{+L} (\psi_r H \psi_s - \psi_s H \psi_r) \, dx \tag{32}
\]

The integrals in Eq. (32) can be expanded in two different, although equivalent, ways. The first one proceeds from the explicit substitution of the hamiltonian and subsequent execution of the integrals to yield

\[
\int_{-L}^{+L} (\psi_r H \psi_s - \psi_s H \psi_r) \, dx = \frac{\hbar^2}{2m} \left[ \left( \psi_s \frac{\partial \psi_r}{\partial x} - \psi_r \frac{\partial \psi_s}{\partial x} \right) \bigg|_{x=-L}^{x=+L} - \left( \psi_s \left( \frac{\partial \psi_r}{\partial x} - \frac{\partial \psi_r}{\partial x} \right) \right) \right] \tag{33}
\]

The second one takes advantage of Eq. (26) and gives

\[
\int_{-L}^{+L} (\psi_r H \psi_s - \psi_s H \psi_r) \, dx = (\epsilon_r - \epsilon_s) \int_{-L}^{+L} \psi_s^* \psi_r \, dx \tag{34}
\]

The enforcement of any set in the eigenfunction boundary conditions, which, by the way, we recall are a direct consequence of the wavefunction boundary conditions whose enforcement sanctioned the hermiticity of the hamiltonian [Eqs. (28) and (29)], makes vanish the right-hand side of Eq. (33) and produces in cascade the following consequences. Equation (33) reduces to

\[
\int_{-L}^{+L} (\psi_r H \psi_s - \psi_s H \psi_r) \, dx = 0 \tag{35}
\]

which looks like the analog of Eq. (17) in terms of the eigenfunctions and is taken as the starting point to introduce the concept of hermiticity in some textbooks [7]. With
Eq. (35) in hand, Eq. (32) reconfirms the hermiticity of the hamiltonian. Equation (34) simplifies to
\[
(\epsilon_s - \epsilon_r) \int_{-L}^{+L} \psi_s^* \psi_r \, dx = 0 \tag{36}
\]
Equation (36) is the basis to prove the reality of the eigenvalues and the orthogonality of the eigenfunctions when \( s \neq r \). If degenerate eigenfunctions turn out to exist then we can make recourse to the Gram-Schmidt recipe [3,8] to orthogonalise them but, for the sake of simplicity, we proceed with the assumption of degeneracy absence. In any case, we are free to choose normalised eigenfunctions
\[
\int_{-L}^{+L} \psi_s^* \psi_r \, dx = \delta_{sr} \tag{37}
\]
We have revised and collected Eqs. (32)–(37) here for convenience; some of them will be needed in the forthcoming sections.

3.3. The integral \( I_\Omega \)

The substitution of the hamiltonian in Eq. (9) and the subsequent execution of the integral leads easily to
\[
I_\Omega = \frac{\hbar^2}{2m} \left\{ \left[ \psi^r \frac{\partial}{\partial x} (\Omega \psi) - (\Omega \psi) \frac{\partial \psi^r}{\partial x} \right]_{x=+L} - \left[ \psi^r \frac{\partial}{\partial x} (\Omega \psi) - (\Omega \psi) \frac{\partial \psi^r}{\partial x} \right]_{x=-L} \right\} \tag{38}
\]
We see clearly from Eq. (38) that the influence of the operator \( \Omega \) on the fate of the integral \( I_\Omega \) is unavoidable and not generalisable somehow; it seems that there is no evident manner to use the vanishing of the right-hand side of Eq. (28) to imply the unconditional vanishing of the right-hand side of Eq. (38) whatever the operator \( \Omega \) is. In other words, we are left with no other option than to assign explicitly the operator \( \Omega \) and see what happens. Before engaging in such a task, however, it is convenient at this point to adapt the integral of the commutator in Eq. (8) to the hamiltonian
\[
I_c = \int_{-L}^{+L} \psi^r [H, \Omega] \psi \, dx = -\frac{\hbar^2}{2m} \int_{-L}^{+L} \psi^r \left[ \frac{\partial^2}{\partial x^2}, \Omega \right] \psi \, dx + \int_{-L}^{+L} \psi^r [V, \Omega] \psi \, dx \tag{39}
\]
The last integral in Eq. (8) plays no role because we will consider only time-independent operators.

3.4. Position operator

The substitution of the position operator \( \Omega = x \) in Eq. (38) and further manipulation of the terms yields in general
\[
I_{\Omega=x} = \frac{\hbar^2}{2m} \left\{ \left[ \psi^r \psi + x \left( \psi^r \frac{\partial \psi}{\partial x} - \psi \frac{\partial \psi^r}{\partial x} \right) \right]_{x=+L} - \left[ \psi^r \psi + x \left( \psi^r \frac{\partial \psi}{\partial x} - \psi \frac{\partial \psi^r}{\partial x} \right) \right]_{x=-L} \right\} \tag{40}
\]
or more explicitly

\[
I_{\Omega=x} = \frac{\hbar^2}{2m} \cdot \begin{cases} 
0 & \text{(c)} \\
2L \left[ \left( \psi^* \frac{\partial \psi}{\partial x} \right)_{x=L} - \left( \psi \frac{\partial \psi^*}{\partial x} \right)_{x=-L} \right] & \text{(p)} \\
(\psi^* \psi)_{x=L} - (\psi^* \psi)_{x=-L} & \text{(v)}
\end{cases}
\]

by taking into account the wavefunction boundary conditions. Equation (41) shows flagrantly and unequivocally the evidence that the answer to the question we asked at the end of Sec. 2 regarding the sufficiency of the hamiltonian’s hermiticity to imply the unconditional vanishing of the integral \(I_\Omega\) should be negative. Indeed, Eq. (29) tells us that the hamiltonian is hermitean regardless of which wavefunction boundary conditions are enforced but Eq. (41) clearly says that the integral \(I_{\Omega=x}\) does not vanish with the periodic and vanishing-derivative boundary conditions. The substitution of the position operator \(\psi = x\) in Eq. (39) leads to

\[
I_c = -\frac{i \hbar}{m} \langle p \rangle
\]  

We can now combine Eqs. (41) and (42) as required by Eq. (8), and rearrange the terms a little bit for convenience, to obtain the time derivative of the macroscopic observable position

\[
\frac{d\langle x \rangle}{dt} = \frac{1}{m} \langle p \rangle + \frac{i \hbar}{2m} \cdot \begin{cases} 
0 & \text{(c)} \\
2L \left[ \left( \psi^* \frac{\partial \psi}{\partial x} \right)_{x=L} - \left( \psi \frac{\partial \psi^*}{\partial x} \right)_{x=-L} \right] & \text{(p)} \\
(\psi^* \psi)_{x=L} - (\psi^* \psi)_{x=-L} & \text{(v)}
\end{cases}
\]

We deduce from Eq. (43) that only confinement (c) produces an equation compliant with the one given by Ehrenfest [Eq. (2a)]; the other boundary conditions do not. With the replacement

\[
\left( \psi \frac{\partial \psi^*}{\partial x} \right)_{x=-L} = \left( \psi \frac{\partial \psi^*}{\partial x} \right)_{x=L}
\]

permitted by the periodic boundary conditions, Eq. (43)(p) can be slightly modified into the form

\[
\frac{d\langle x \rangle}{dt} = \frac{1}{m} \langle p \rangle - \frac{i \hbar}{2m} \cdot 2L \left[ \left( \psi \frac{\partial \psi^*}{\partial x} \right)_{x=L} - \left( \psi \frac{\partial \psi^*}{\partial x} \right)_{x=-L} \right]
\]

that coincides with the equation given at the bottom of page 737 in Hill’s paper [11] (notation correspondence: \(2L \to (b - a); \psi^* \to \Psi\) and with Eq. (A.1) at page 163 of Alonso et al.’s paper [13] (notation correspondence: \(2L \to L; \psi^* \to \Psi\). We can go one
On Ehrenfest’s theorem

level deeper than Eq. (43) by substituting into it the wavefunction general solution to obtain the expression for the time derivative

\[
\frac{d\langle x \rangle}{dt} = \frac{1}{m} \langle p \rangle + \frac{i\hbar}{2m} \sum_{r,s} c_r c_s \exp \left( i \frac{\epsilon_s - \epsilon_r}{\hbar} t \right) \cdot \left\{ 2L \left[ \left( \psi_s \frac{\partial \psi_r}{\partial x} \right)_{x=L} - \left( \psi_r \frac{\partial \psi_s}{\partial x} \right)_{x=-L} \right] + \left( \psi_s^* \psi_r \right)_{x=L} - \left( \psi_s^* \psi_r \right)_{x=-L} \right\}
\]

in terms of the eigenfunctions. The motivation for the procedure we have followed so far to deduce the time derivative of \( \langle x \rangle \) resides in the necessity to find out the behaviour of the integral \( I_{\Omega} \) [Eq. (38)] with respect to the established hermiticity of the hamiltonian. However, there is an alternative, and certainly more direct, manner to deduce the time derivative in question; it starts from the definition of \( \langle x \rangle \) that takes advantage of the wavefunction general solution

\[
\langle x \rangle = \int_{-L}^{+L} \psi^* \psi dx = \sum_{r,s} c_r c_s \exp \left( i \frac{\epsilon_s - \epsilon_r}{\hbar} t \right) \cdot \int_{-L}^{+L} \psi^*_r \psi_r dx
\]

A straightforward time derivation of Eq. (47) gives

\[
\frac{d\langle x \rangle}{dt} = \frac{i}{\hbar} \sum_{r,s} c_r c_s^* (\epsilon_s - \epsilon_r) \exp \left( i \frac{\epsilon_s - \epsilon_r}{\hbar} t \right) \cdot \int_{-L}^{+L} \psi^*_r \psi_r dx
\]

Equation (48) displays an interesting characteristic if compared to Eq. (46): there is no explicit trace in it of any boundary conditions. Of course, we expect equivalence between Eqs. (46) and (48) but we need to find out what is behind \( \langle p \rangle \) in order to have a better insight into this matter. Therefore, we postpone the completion of this task to Sec. 3.6.

3.5. Momentum operator

We simply have to re-walk the algebraic trail followed for the position operator in Sec. 3.4. We substitute in Eq. (38) the momentum operator \( \Omega = p \) defined in Eq. (30) and carry out the integral; a bit of attention should be payed to the appearance of the wavefunction’s spatial second derivatives but they can be easily disposed of by extracting them from Eq. (20). When all the necessary algebra is taken care of, the final result reads

\[
I_{\Omega=p} = \frac{\hbar}{i} \cdot \left\{ - \frac{\hbar^2}{2m} \left[ \left( \frac{\partial \psi^*}{\partial x} \frac{\partial \psi}{\partial x} \right)_{x=L} - \left( \frac{\partial \psi^*}{\partial x} \frac{\partial \psi}{\partial x} \right)_{x=-L} \right] + \left( \psi^* V^* \psi - i \hbar \psi^* \frac{\partial \psi}{\partial t} \right)_{x=L} - \left( \psi^* V^* \psi - i \hbar \psi^* \frac{\partial \psi}{\partial t} \right)_{x=-L} \right\}
\]
Here again we see that the integral may differ from zero according to the enforced boundary conditions; concerning confinement and periodicity, the situation in Eq. (49) is reversed with respect to Eq. (41). The substitution of the momentum operator $\frac{\partial}{\partial x} = \hat{p}$ in Eq. (39) leads to the well known force term

$$I_c = \frac{\hbar}{i} \int_{-L}^{+L} \psi^* \left( -\frac{\partial V}{\partial x} \right) \psi \, dx$$

The combination of Eqs. (49) and (50) according to Eq. (8) yields the time derivative of the macroscopic observable momentum

$$\frac{d\langle p \rangle}{dt} = \int_{-L}^{+L} \psi^* \left( -\frac{\partial V}{\partial x} \right) \psi \, dx +$$

$$\left\{ \begin{array}{l}
- \frac{\hbar^2}{2m} \left[ \left( \frac{\partial \psi_x}{\partial x} \right)_{x=L} - \left( \frac{\partial \psi_x}{\partial x} \right)_{x=-L} \right] \\
0 \\
\left( \psi^* \psi - \frac{i}{\hbar} \psi^* \frac{\partial \psi}{\partial t} \right)_{x=L} - \left( \psi^* \psi - \frac{i}{\hbar} \psi^* \frac{\partial \psi}{\partial t} \right)_{x=-L}
\end{array} \right\}_{(c)}_{(p)}_{(v)} \tag{51}$$

Equation (51) tells us that, this time, only the periodic boundary conditions (p) give back an equation compliant with the one given by Ehrenfest [Eq. (2b)]; surprisingly, confinement (c) does not, its duly conforming to Eq. (2a) via Eq. (43)(c) notwithstanding. Equation (51) (c) coincides with Eq. (A.2) at page 164 of Alonso et al.'s paper [13] (notation correspondence: $2L \rightarrow L$; $\psi^* \rightarrow \bar{\psi}$). As we did in Sec. 3.4, here also we can push the details one step deeper than Eq. (51) by taking advantage of the wavefunction general solution to bring forth the eigenfunctions

$$\frac{d\langle p \rangle}{dt} = \sum_{r,s} c_r c_s \exp \left( i \frac{\varepsilon_r - \varepsilon_s}{\hbar} t \right) \cdot$$

$$\left\{ \begin{array}{l}
\int_{-L}^{+L} \psi_s^* \left( -\frac{\partial V}{\partial x} \right) \psi_r \, dx - \frac{\hbar^2}{2m} \left[ \left( \frac{\partial \psi_x}{\partial x} \right)_{x=L} - \left( \frac{\partial \psi_x}{\partial x} \right)_{x=-L} \right] \\
0 \\
\left[ (\varepsilon_r - V) \psi_r \psi_s \right]_{x=L} - \left[ (\varepsilon_r - V) \psi_s \psi_r \right]_{x=-L}
\end{array} \right\}_{(c)}_{(p)}_{(v)} \tag{52}$$

A more direct manner to deduce the time derivative of $\langle p \rangle$ exists too. It consists in carrying out the time derivative of the definition

$$\langle p \rangle = \int_{-L}^{+L} \psi \frac{\hbar}{i} \frac{\partial \psi}{\partial x} \, dx = \sum_{r,s} c_r c_s \exp \left( i \frac{\varepsilon_r - \varepsilon_s}{\hbar} t \right) \cdot \int_{-L}^{+L} \psi_s^* \frac{\hbar}{i} \frac{\partial \psi}{\partial x} \, dx \tag{53}$$
On Ehrenfest’s theorem

13
to obtain an expression

\[ \frac{d\langle p \rangle}{dt} = \sum_{r,s} c_r c_s^* (\epsilon_s - \epsilon_r) \exp \left( i \frac{\epsilon_s - \epsilon_r}{\hbar} t \right) \cdot \int_{-L}^{+L} \psi_s^* \frac{\partial \psi_r}{\partial x} \, dx \]  

once again apparently free from the presence of the boundary conditions. Equation (52) looks rather complex because it involves explicitly integrals of the physical potential’s derivative and boundary conditions while Eq. (54) looks relatively simpler; are they equivalent? The answer requires to expand the eigenstates’ contributions

\[ \int_{-L}^{+L} \psi_s^* \left( - \frac{\partial V}{\partial x} \right) \psi_r \, dx \]  

appearing in Eq. (52) and we will come back to it in Sec. 3.7. For the time being, we can transform Eq. (46) a bit further due to the availability of Eq. (53) and complete the task, put on hold at the end of Sec. 3.4, concerned with finding out whether or not Eqs. (46) and (48) are equivalent.

3.6. Equivalence of alternative expressions for the time derivative of the macroscopic observable position

The substitution of Eq. (53) into Eq. (46) yields

\[ \frac{d\langle x \rangle}{dt} = \sum_{r,s} c_r c_s^* \exp \left( i \frac{\epsilon_s - \epsilon_r}{\hbar} t \right) \cdot \left[ \begin{array}{c} 0 \\ 2L \left( \psi_s^* \frac{\partial \psi_r}{\partial x} \right)_{x=+L} - \left( \psi_r \frac{\partial \psi_s^*}{\partial x} \right)_{x=-L} \\ (\psi_s^* \psi_r)_{x=+L} - (\psi_s^* \psi_r)_{x=-L} \end{array} \right] \]  

Visual inspection indicates that the equivalence proof requires the term

\[ \frac{i}{\hbar} (\epsilon_s - \epsilon_r) \cdot \int_{-L}^{+L} \psi_s^* x \psi_r \, dx \]

of Eq. (48) to coincide with the term

\[ \frac{1}{m} \int_{-L}^{+L} \psi_s^* \frac{\hbar}{i} \frac{\partial \psi_r}{\partial x} \, dx + \frac{i \hbar}{2m} \left[ \begin{array}{c} 0 \\ 2L \left( \psi_s^* \frac{\partial \psi_r}{\partial x} \right)_{x=+L} - \left( \psi_r \frac{\partial \psi_s^*}{\partial x} \right)_{x=-L} \\ (\psi_s^* \psi_r)_{x=+L} - (\psi_s^* \psi_r)_{x=-L} \end{array} \right] \]  

(c) (p) (v)
of Eq. (56). In order to show that this is indeed what happens, we need to rewind to Eq. (34). As it is well known, the equation’s integral form descends from the equality of the respective integrands

\[(\epsilon^*_s - \epsilon_r) \psi^*_s \psi_r = (\psi_r H \psi^*_s - \psi^*_s H \psi_r)\]  

(57)

In Eq. (57), we can remove the complex-conjugation symbol \(^\ast\) from \(\epsilon_s\) because the Hamiltonian is hermitean; moreover, we can adapt the right-hand side with the help of Eq. (33) reformulated in local form

\[
\psi_r H \psi^*_s - \psi^*_s H \psi_r = \frac{\hbar^2}{2m} \frac{\partial}{\partial x} \left( \psi^*_s \frac{\partial \psi_r}{\partial x} - \psi_r \frac{\partial \psi^*_s}{\partial x} \right)
\]  

(58)

Equation (58) turns Eq. (57) into

\[(\epsilon_s - \epsilon_r) \psi^*_s \psi_r = \frac{\hbar^2}{2m} \frac{\partial}{\partial x} \left( \psi^*_s \frac{\partial \psi_r}{\partial x} - \psi_r \frac{\partial \psi^*_s}{\partial x} \right)\]  

(59a)

Equation (59a) is the starting point of the proof we are seeking; it can also be reached, and perhaps in a cleaner way, from the appropriate manipulation of the time-independent Schrödinger equation [Eq. (26)] and its complex conjugate. Next step consists in the multiplication by \(x i/\hbar\) on both sides

\[
\frac{i}{\hbar} (\epsilon_s - \epsilon_r) \psi^*_s x \psi_r = \frac{i \hbar}{m} \frac{\partial}{\partial x} \left( \psi^*_s \frac{\partial \psi_r}{\partial x} - \psi_r \frac{\partial \psi^*_s}{\partial x} \right)
\]  

(59b)

followed by the incorporation of \(x\) inside the derivative and subsequent transformations

\[
\frac{i}{\hbar} (\epsilon_s - \epsilon_r) \psi^*_s x \psi_r = \frac{1}{m} \frac{h}{i} \frac{\partial \psi^*_s}{\partial x} + \frac{i \hbar}{2m} \left[ x \left( \psi^*_s \frac{\partial \psi_r}{\partial x} - \psi_r \frac{\partial \psi^*_s}{\partial x} \right) + \psi^*_s \psi_r \right]
\]  

(59c)

Finally, the integration of Eq. (59c) gives the proof of equivalence

\[
\frac{i}{\hbar} (\epsilon_s - \epsilon_r) \cdot \int_{-L}^{+L} \psi^*_s x \psi_r dx = \left[
\begin{array}{c}
0 \\
\frac{1}{m} \int_{-L}^{+L} \psi^*_s \frac{h}{i} \frac{\partial \psi_r}{\partial x} dx + \frac{i \hbar}{2m} \left[ 2L \left( \psi^*_s \frac{\partial \psi_r}{\partial x} \right)_{x=+L} - \left( \psi^*_s \frac{\partial \psi_r}{\partial x} \right)_{x=-L} \right] \\
\left( \psi^*_s \psi_r \right)_{x=+L} - \left( \psi^*_s \psi_r \right)_{x=-L}
\end{array}
\right]
\]  

(59d)

between Eqs. (46) and (48). The striking features of the simple left-hand side of Eq. (59d) are: a) it spares us the necessity to calculate the eigenfunctions’ spatial derivative contained in the integrand of the first term on the right-hand side, a perhaps numerically convenient circumstance in the cases in which the eigenfunctions are not available in analytical form; b) it carries smoothly and implicitly the knowledge of the boundary conditions contained explicitly in the second term on the right-hand side. In conclusion, we remark that the presence of the triple term in Eq. (46) is indispensable for the proof of equivalence with Eq. (48). Such an indispensability hopelessly crosses out the attribute of completeness from Ehrenfest’s Eq. (2a).
3.7. Equivalence of alternative expressions for the time derivative of the macroscopic observable momentum

In this section, we return to the question formulated at the end of Sec. 3.5 concerned with the equivalence of Eqs. (52) and (54). We shift, therefore, our attention to the macroscopic observable force

\[ \int_{-L}^{L} \psi^* \left( -\frac{\partial V}{\partial x} \right) \psi \, dx = \sum_{r,s} c_r c_s^* \exp \left( i\frac{\varepsilon_r - \varepsilon_s}{\hbar} t \right) \int_{-L}^{L} \psi_r^* \left( -\frac{\partial V}{\partial x} \right) \psi_r \, dx \]  

(60)

and, in particular, to the eigenstates’ contributions [Eq. (55)] in the addenda on the right-hand side of Eq. (60). We look at these terms as channels through which the influence of the environment on the particle becomes manifest; they are in a kind of stand-by state awaiting activation upon explicit assignment of the physical input represented by the potential \( V(x) \). Yet, the eigenstates’ contributions possess a very interesting property that does not require the explicit knowledge of the potential and that can be dug up from the time-independent Schrödinger equation [Eq. (26)], if we arm ourselves with a bit of prudent dexterity and, above all, solid patience to deal with the necessary algebra.

We begin from the time-independent Schrödinger equation for the eigenstate \( r \)

\[ -\frac{\hbar^2}{2m} \frac{\partial^2 \psi_r}{\partial x^2} + V \psi_r = \varepsilon_r \psi_r \]  

(61a)

and the complex conjugate for the eigenstate \( s \)

\[ -\frac{\hbar^2}{2m} \frac{\partial^2 \psi_s^*}{\partial x^2} + V \psi_s^* = \varepsilon_s \psi_s^* \]  

(61b)

and then take the spatial derivative of both

\[ -\frac{\hbar^2}{2m} \frac{\partial^2 \psi_r}{\partial x^2} \frac{\partial}{\partial x} + \frac{\partial V}{\partial x} \frac{\partial \psi_r}{\partial x} + V \frac{\partial \psi_r}{\partial x} = \varepsilon_r \frac{\partial \psi_r}{\partial x} \]  

(61c)

\[ -\frac{\hbar^2}{2m} \frac{\partial^2 \psi_s^*}{\partial x^2} \frac{\partial}{\partial x} + \frac{\partial V}{\partial x} \frac{\partial \psi_s^*}{\partial x} + V \frac{\partial \psi_s^*}{\partial x} = \varepsilon_s \frac{\partial \psi_s^*}{\partial x} \]  

(61d)

After, we multiply Eq. (61c) by \( \psi_s^* \), Eq. (61d) by \( \psi_r \), add them and rearrange terms to obtain

\[ -\frac{\hbar^2}{2m} \left( \psi_r^* \frac{\partial^2}{\partial x^2} \frac{\partial}{\partial x} + \psi_r \frac{\partial^2}{\partial x^2} \frac{\partial}{\partial x} \right) + 2 \psi_r^* \frac{\partial V}{\partial x} \psi_r + V \frac{\partial \psi_r^* \psi_r}{\partial x} = \varepsilon_r \psi_r \frac{\partial \psi_r}{\partial x} + \varepsilon_s \psi_s^* \frac{\partial \psi_s^*}{\partial x} \]  

(61e)

The term underlined in Eq. (61e) represents our target. The transformation of Eq. (61e) to the form

\[ \psi_r^* \left( -\frac{\partial V}{\partial x} \right) \psi_r = (\varepsilon_r - \varepsilon_r) \psi_r \frac{\partial \psi_r}{\partial x} + \frac{\partial}{\partial x} \left( (\varepsilon_r - V) \psi_r \psi_r^* + \frac{\hbar^2}{2m} \frac{\partial \psi_r^*}{\partial x} \frac{\partial \psi_r}{\partial x} \right) \]  

(61f)
On Ehrenfest’s theorem

involves juggling with derivatives’ expansion and regrouping; second derivatives appear in the course of the process but they can be disposed of with the aid of Eqs. (61a) and (61b). The final step is the integration of (61f) to yield

$$\int_{-L}^{+L} \psi_\varepsilon^* \left( -\frac{\partial V}{\partial x} \right) \psi_r \, dx = (\varepsilon_s - \varepsilon_r) \int_{-L}^{+L} \psi_\varepsilon^* \frac{\partial \psi_r}{\partial x} \, dx +$$

$$\left\{ \frac{\hbar^2}{2m} \left[ \left( \frac{\partial \psi_r x}{\partial x} \frac{\partial \psi_s}{\partial x} \right)_{x=L} - \left( \frac{\partial \psi_r x}{\partial x} \frac{\partial \psi_s}{\partial x} \right)_{x=-L} \right] \right\} (c)$$

$$0 \quad (p) \quad (61g)$$

$$\left\{ [\varepsilon_r x - V] \psi_\varepsilon^* \psi_r x_{x=L} - [\varepsilon_r x - V] \psi_\varepsilon^* \psi_r x_{x=-L} \right\} (v)$$

Equation (61g) is as remarkable as Eq. (59d); if we introduce it into Eq. (52) then the triple term cancels out and what remains is precisely Eq. (54). We have, thus, proven the equivalence of Eqs. (52) and (54). The presence of the triple term in Eq. (52), and, a fortiori, of the triple term in Eq. (51), is essential for the proof and inescapably removes the attribute of completeness from Ehrenfest’s Eq. (2b).

3.8. Postliminary considerations

3.8.1. A moment of reflection. Let us spend a moment to reflect about what we have done and achieved so far. In the paragraph concluding Sec. 2, we questioned the sufficiency of the hamiltonian’s hermiticity to make the integral $I_\Omega$ [Eq. (9)] vanish regardless of which operator $\Omega$ intervenes in it. In Secs. 3.4 and 3.5, we found out the answer to be a resolute and unquestionable “No, it is not!” by executing the integral $I_\Omega$ with position and momentum operators. Systematic examination brought to surface the fundamental role played by the wavefunction boundary conditions and led to the time derivatives of the corresponding macroscopic observables given in Eqs. (43) and (51). The gears of the mathematical machinery moved smoothly and consistently, surprisingly even in the case of the vanishing-derivative (v) boundary conditions for which we know we are walking on a physically shaky ground due to non-hermiticity of the momentum operator and the consequent complex-valuedness of its macroscopic observable [Eq. (31)]. Now, Eqs. (43) and (51) differ from Eqs. (2) and suggest, at least in principle, a quantum-mechanical macroscopic description of the particle’s statics and dynamics substantially different from the, supposedly classical-mechanical, description provided by Eqs. (2). So, it comes natural to ask: what is the physical meaning of the additional boundary terms appearing in Eqs. (43) and (51) but missing in Ehrenfest’s formulation of his theorem? Obviously, the question sounds meaningful only for confinement (c) and periodicity (p) boundary conditions. It is clearly of doubtful significance for vanishing-derivative (v) boundary conditions due to the complex-valuedness shortcoming affecting the macroscopic observable momentum; as a
matter of fact, with the obtainment of Eq. (43)(v) and Eq. (51)(v) we have been allowed to go as far as mathematical dexterity permits but, now that we specifically step into a purely physical context, we must diligently suspend consideration of the (v) case and concentrate our attention on the (c) and (p) cases.

3.8.2. Physical meaning of the boundary terms. Equation (6) is a good starting point for the quest regarding the physical meaning of the boundary terms in Eqs. (43) and (51). We look at its left-hand side with the classical-mechanics perspective in mind and we see a macroscopically observable property that belongs to the particle, a physical system that we (are habituated to) conceive punctiform in nature and, therefore, occupying geometrical points inside (and outside of) the spatial domain. The right-hand side reflects the quantum-mechanics viewpoint: the same property is distributed in the spatial domain with density $\Psi^* \Omega \Psi$, the physical system may still be the particle but our habit to conceive it punctiform and localised in geometrical points is not really necessary anymore. We focus on the quantum-mechanics viewpoint and, with anticipated expectation of clarification from the fluid-dynamics formulation of quantum mechanics, pioneered by de Broglie [24–26], Madelung [27], Bohm [28,29], Takabayasi [30,31] and still being explored [32–34] in more recent years, we ask: how does the macroscopic-observable density $\Psi^* \Omega \Psi$ change with time? Well, we simply have to repeat the same time-differentiation exercise that leads to Eq. (8) but we have to work locally this time, and with the hamiltonian specified in Eq. (19). The reward at the end of the algebraic procedure is

$$\frac{\partial}{\partial t}(\Psi^* \Omega \Psi) + \frac{\partial}{\partial x} \left\{ \frac{\hbar}{2mi} \left[ \Psi^* \frac{\partial}{\partial x} (\Omega \Psi) - (\Omega \Psi) \frac{\partial \Psi^*}{\partial x} \right] \right\} =$$

$$\frac{i}{\hbar} \Psi^* \left[ \left( -\frac{\hbar^2}{2m} \frac{\partial^2}{\partial x^2} + V \right), \Omega \right] \Psi + \Psi^* \frac{\partial \Omega}{\partial t} \Psi \quad (62a)$$

It is important to keep in mind that there is no physical information in Eq. (62a) that is not already contained in Eq. (8), conjoined with Eq. (19), and viceversa; both equations convey the same physics in local and integral forms, respectively. Eq. (62a) reveals the typical mathematical structure of a fluid-dynamics balance equation; with regard to the macroscopically observable property $\langle \Omega \rangle$, there are: on the left-hand side, time derivative of its density and divergence of its flux

$$S_\Omega = \frac{\hbar}{2mi} \left[ \Psi^* \frac{\partial}{\partial x} (\Omega \Psi) - (\Omega \Psi) \frac{\partial \Psi^*}{\partial x} \right] \quad (62b)$$

responsible for the local transport throughout the spatial domain, and on the right-hand side, its production term

$$P_\Omega = \frac{i}{\hbar} \Psi^* \left[ \left( -\frac{\hbar^2}{2m} \frac{\partial^2}{\partial x^2} + V \right), \Omega \right] \Psi + \Psi^* \frac{\partial \Omega}{\partial t} \Psi \quad (62c)$$

that accounts for the creation/destruction per unit time in the unit length. In the last sentence, we have clearly spoken in fluid-dynamics parlance. In order to be sure that
we are on the right track, we set $\Omega = 1$ in Eqs. (62a) and (62b) to retrieve as particular case the equations for probability

$$\frac{\partial}{\partial t}(\Psi^* \Psi) + \frac{\partial}{\partial x} \left[ \frac{\hbar}{2mi} \left( \Psi^* \frac{\partial \Psi}{\partial x} - \Psi \frac{\partial \Psi^*}{\partial x} \right) \right] = 0 \quad (63a)$$

and for its current density

$$S_{\Omega=1} = \frac{\hbar}{2mi} \left( \Psi^* \frac{\partial \Psi}{\partial x} - \Psi \frac{\partial \Psi^*}{\partial x} \right) \quad (63b)$$

that Bohm proposed at page 83 of his textbook [5]. Additionally, Eq. (62c) indicates that the production term vanishes identically

$$P_{\Omega=1} = 0 \quad (63c)$$

and, in so doing, confers the conservation attribute to probability: it cannot be either created or destroyed, exactly as it happens for total mass in fluid dynamics. As a matter of fact, if we multiply Eqs. (63a) and (63b) by $m$ then what we obtain may very well be interpreted as balance equation and flux of particle’s mass. Bohm remarked wittingly

“This idea that probability flows through space more or less like a fluid is very useful physically.

Yes, definitely. But probability is not the only one that “flows through space”: Eq. (62a) unambiguously tells us that the same conceptual idea applies to any macroscopic observable. If we integrate it on the spatial domain then the flux-divergence term will yield the difference of the fluxes evaluated at the boundaries

$$S_{\Omega(+L)} - S_{\Omega(-L)} =$$

$$\frac{\hbar}{2mi} \left[ \Psi^* \frac{\partial}{\partial x} (\Omega \Psi) - (\Omega \Psi) \frac{\partial \Psi^*}{\partial x} \right]_{x=+L} - \frac{\hbar}{2mi} \left[ \Psi^* \frac{\partial}{\partial x} (\Omega \Psi) - (\Omega \Psi) \frac{\partial \Psi^*}{\partial x} \right]_{x=-L} = \frac{1}{i\hbar} I_{\Omega} \quad (64)$$

which, save for the irrelevant multiplicative factor $1/i\hbar$, matches precisely the integral $I_{\Omega}$ [Eq. (38)] that originates the boundary terms in Eqs. (43) and (51). There is, therefore, only one possible physical interpretation for those terms consistent with the fluid-dynamics perspective to which Eq. (62a) belongs: they represents the exchange of the corresponding macroscopically observable property between the physical system residing inside the spatial domain and its external environment residing outside. Such exchange is necessarily governed by the wavefunction’s boundary conditions and the fine details of its physical interpretation are achievable only after the specification of the operator $\Omega$. 
3.8.3. Position operator When dealing with the position operator, the application of Eq. (62a) should not be thoughtlessly rushed but meditated with a grain of circumspection. Fluid dynamicists know very well that the physical meaningfulness of a balance equation hangs on an important requirement for the property being balanced: it must be extensive. In other words, a balance equation like Eq. (62a) can be formulated only for properties of a physical system that are proportional to the extension of the spatial domain that contains the physical system [35]. Mass, momentum, angular momentum, and energy are examples of extensive properties. Position is not but we can elude this minor conceptual obstacle by setting $\Theta = mx$ in Eqs. (62) in order to be formally compliant with the extensiveness requirement. Then we obtain the balance equation

$$\frac{\partial}{\partial t}(\Psi^* m x \Psi) + \frac{\partial}{\partial x}(S_{mx}) = P_{mx}$$  \hspace{1cm} (65a)

with flux

$$S_{mx} = \frac{\hbar}{2i} \left[ \Psi^* \Psi + x \left( \Psi^* \frac{\partial \Psi}{\partial x} - \Psi \frac{\partial \Psi^*}{\partial x} \right) \right]$$  \hspace{1cm} (65b)

and production

$$P_{mx} = \Psi \frac{\hbar}{i} \frac{\partial \Psi}{\partial x}$$  \hspace{1cm} (65c)

Equation (65a) constitutes the local form of Eq. (43). We recognise from Eq. (65b) the explicit correspondence between the boundary terms in Eq. (43), multiplied by $m$, and the exchange term generated by the formal integration of Eq. (65a) on the spatial domain

$$S_{mx}(+L) - S_{mx}(-L) = -\frac{i \hbar}{2} \begin{cases} 0 \\ 2L \left[ \left( \Psi^* \frac{\partial \Psi}{\partial x} \right)_{x=+L} - \left( \Psi \frac{\partial \Psi^*}{\partial x} \right)_{x=-L} \right] \end{cases}$$ \hspace{1cm} (66)

We may also look at them as an offset between the macroscopically observable momentum $\langle p \rangle$ of the particle and the amount of momentum attributable to the product of its mass and velocity $m \cdot d\langle x \rangle/dt$. Thus, quantum mechanics and classical mechanics clearly agree in the (c) case because the exchange term vanishes but not in the (p) case because the exchange term stands firmly out. In this regard, Hill [11] has investigated the statics of a free particle $[V(x) = 0]$ in a generic stationary state $(d\langle x \rangle/dt = 0)$ with periodic (p) boundary conditions $(\langle p \rangle \neq 0)$ and has proven analytically the necessity of the additional momentum supplied by the exchange term to keep Eq. (45) in balance. However, his explanation for such an occurrence, provided at page 738 of his article, is only of mathematical nature. Also, Reif proposed at page 356 of his textbook [22] an interesting problem regarding the motion of a particle on a circumference, again involving periodic (p) boundary conditions therefore, that offers an appropriate scenario to scrutinise the physical meaning of the boundary terms in Eq. (43)(p); De Vincenzo [36] has discussed classical and quantum descriptions of this problem in details and we refer the interested reader to his well-written paper.
3.8.4. Momentum operator  If we substitute in Eqs. (62) the momentum operator \( \Omega = p \) defined in Eq. (30) then we obtain the particle’s momentum balance equation

\[
\frac{\partial}{\partial t} \left( \psi \frac{\hbar}{i} \frac{\partial \psi}{\partial x} \right) + \frac{\partial}{\partial x} \left( S_p \right) = P_p \tag{67a}
\]

with flux

\[
S_p = \frac{\hbar^2}{2m} \left( \frac{\partial \psi}{\partial x} \frac{\partial \psi^*}{\partial x} - \psi^* \frac{\partial^2 \psi}{\partial x^2} \right) \tag{67b}
\]

and production

\[
P_p = \psi^* \left( -\frac{\partial V}{\partial x} \right) \psi \tag{67c}
\]

Equations (67) display an outstanding analogy with fluid dynamics, or, perhaps better, with the mechanics of continuous media, that encourages to draw the following remarkable deductions. In the spatial domain, there exists a stress distribution with tensor \(-S_p\) (there is only the \(xx\)-component in our one-dimensional case) and force density \(-\partial S_p/\partial x\) induced by external forces applied at the boundaries that turn out to be precisely the boundary terms in Eq. (51)

\[
[-S_p(+L)] - [-S_p(-L)] = \int_{-L}^{+L} \frac{\partial}{\partial x} (-S_p) \, dx =
\left\{
-\frac{\hbar^2}{2m} \left[ \left( \frac{\partial \psi}{\partial x} \frac{\partial \psi^*}{\partial x} \right)_{x=+L} - \left( \frac{\partial \psi}{\partial x} \frac{\partial \psi^*}{\partial x} \right)_{x=-L} \right] \tag{c}
\right.
\]

\[
= 0 \tag{p}
\]

The external forces, also interpretable as exchange of momentum, are necessarily due to the confining walls in the (c) case and Eq. (68)(c), perhaps surprisingly, tells us that those forces are finite, an outcome in full contraposition with the widespread belief that forces due to confining walls should be infinite instead. The external forces vanish in the (p) case. Furthermore, the force density due to the physical potential [Eq. (67c)] plays the role of a field responsible for the production of momentum. For the sake of completeness, we wish to mention that both Eqs. (67a) and (67b) can be turned into more mathematically symmetric, although clearly physically equivalent, forms. The key for the transformation is the hermiticity of the momentum operator which holds in the (c) and (p) cases [Eq. (31)]. The recipe for the transformation calls for the complex conjugation of Eq. (67a), adding the outcome to Eq. (67a) and dividing by 2; that leads to the final balance equation

\[
\frac{\partial}{\partial t} \left[ \frac{\hbar}{2i} \left( \psi \frac{\partial \psi}{\partial x} - \psi^* \frac{\partial \psi^*}{\partial x} \right) \right] + \frac{\partial}{\partial x} \left( S_p' \right) = P_p \tag{69a}
\]

with flux

\[
S_p' = \frac{\hbar^2}{2m} \left( \frac{\partial \psi}{\partial x} \frac{\partial \psi^*}{\partial x} - \frac{1}{2} \psi^* \frac{\partial^2 \psi}{\partial x^2} - \frac{1}{2} \psi \frac{\partial^2 \psi^*}{\partial x^2} \right) \tag{69b}
\]
The momentum densities in Eqs. (67a) and (69a) are equivalent
\[ \langle p \rangle = \int_{-L}^{+L} \Psi \frac{\hbar}{i} \frac{\partial \Psi}{\partial x} \, dx = \langle p \rangle' = -\frac{\hbar}{i} \int_{-L}^{+L} \Psi \frac{\partial \Psi}{\partial x} \, dx = \frac{\hbar}{2i} \int_{-L}^{+L} \left( \frac{\Psi}{i} \frac{\partial \Psi}{\partial x} \right) \, dx \]  
(70)
and the boundary-flux difference is expectedly invariant
\[ S_P(+L) - S_P(-L) = S_P'(+L) - S_P'(-L) \]  
(71)
Equations (67a) and (69a) constitute the local form of Eq. (51). By looking at them in an attempt to rescue Ehrenfest’s formulation [Eqs. (2)] of his theorem at least in the (c) case, a concerned student may raise the following, admittedly rather gripping, question: is there a way to transform their flux-divergence term, induced by the external forces due to the confining walls, into a production term structured as Eq. (67c)? In mathematical terms, and selecting Eq. (69b) for example, we should seek a potential \( V' \) that satisfies the condition
\[ \Psi \frac{-\partial V'}{\partial x} \psi = -\frac{\hbar^2}{2m} \frac{\partial}{\partial x} \left( \frac{\partial \psi}{\partial x} \frac{\partial \psi}{\partial x} - \frac{1}{2} \frac{\partial^2 \psi}{\partial x^2} \right) \]  
(72a)
so that Eq. (51)(c) would undoubtedly turn into
\[ \frac{d\langle p \rangle}{dt} = \int_{-L}^{+L} \left[ \frac{-\partial}{\partial x} \left( V + V' \right) \right] \psi \, dx \]  
(72b)
and justify the conclusion that if we consider the \textit{total} potential \( V + V' \) then Ehrenfest’s formulation [Eq. (2)] of his theorem is fine because \textit{all} the forces are taken into account as derivable from a potential. Indeed, it is relatively not difficult to extract the potential \( V' \) from Eq. (72a). As a matter of fact, we can even ignore the terms with the second derivatives because, upon integration, they vanish in the (c) case; thus, we are allowed to simplify the basic condition for the quest of the potential \( V' \) as follows
\[ \Psi \frac{-\partial V'}{\partial x} \psi = -\frac{\hbar^2}{2m} \frac{\partial}{\partial x} \left( \frac{\partial \psi}{\partial x} \frac{\partial \psi}{\partial x} \right) \]  
(72c)
In the (c) case, Eq. (72c) predicts
\[ \left. -\left( \frac{\partial V'}{\partial x} \right) \right|_{x=\pm L} \to \infty \]  
(72d)
at the confining walls if we assume the finiteness of the right-hand side. Admittedly, all appears correct mathematically. However, in our opinion, we believe there is no much physical content in the mathematical sophistry of Eqs. (72) because the potential \( V' \) (i) does not belong to the hamiltonian and, therefore, does not participate in the determination of the wavefunction \( \psi \), (ii) can be evaluated \textit{only after} that the wavefunction \( \psi \) has been determined, and (iii) turns out to be, after all, just an \textit{ad hoc} term introduced to camouflage a flux divergence as a production for the purpose
of making Eq. (51)(c) look like Eq. (2b). Another attemptable rescue line could ignore Eqs. (72a) and (72c), de facto the boundary terms in Eq. (51)(c), trust the unconditional applicability of both Eqs. (72b) and (72d), and blame the lack of operativeness of Eq. (72b) to the drawback of the wall-related potential \( V' \) emanating from Eq. (72d): the force \(-\partial V'/\partial x\) cannot be cast in a form for which Eq. (72b) can be directly applied. This argumentation saves the form of Eq. (72b) to the detriment of its operativeness; indeed, how can we then calculate the macroscopically observable dynamics of the particle in the (c) case if the operativeness of Eq. (72b) is disabled by the presence of the confining walls? Additionally, the reconciliation of Eq. (72b) with the presence of the boundary terms in Eq. (51)(c) would still remain an intricate unsettled question.

When contemplating these rescue attempts, a witty statement of Sutcliffe (at top of page 35 of) [37] comes to mind to portray them as typical examples in which

... one artificially forces on the system one’s preconceptions about behaviour.

In conclusion, we feel comfortable with the physical interpretation attached to Eqs. (67) in local form and to Eq. (51)(c,p) in integral form because it is more complete, free of conceptual doubts and operative from a calculation point of view.

3.9. Numerical test case

3.9.1. Introductory reflections. The theoretical considerations of the precedent sections align consistently with those of Hill [11], Alonso et al [13,14] and De Vincenzo [15, 16] regarding the presence of the boundary terms in Eqs. (43) and (51) and invalidate the completeness of Ehrenfest’s theorem in the formulation he gave [Eqs. (2)]. We wish to complement and to corroborate the theory dealt with so far with a numerical test case because we are convinced that, from a pedagogical point of view, fully worked-out numerical examples help greatly the students to bring theoretical and mathematical abstraction within their grasp. We believe it is prudent to follow Hill’s choice [11] and start with a statics example. Of course, a dynamics case is certainly more attractive because richer in details but we prefer to proceed in steps of increasing difficulty and, in this respect, we point the impatient reader to De Vincenzo’s study [15] of the one-dimensional dynamics of a particle subjected only to the external forces due to the confining walls \([V(x) = 0]\). We will consider only the confinement boundary conditions [Eq. (22)(c) and Eq. (27)(c)]; for convenience, we collect here the relevant equations [Eq. (43)(c) and Eq. (51)(c)]

\[
\frac{d\langle x \rangle}{dt} = \frac{1}{m} \langle p \rangle 
\]

\[
\frac{d\langle p \rangle}{dt} = \int_L^L \Psi^* \left( -\frac{\partial V}{\partial x} \right) \Psi \, dx - \sigma \cdot \frac{\hbar^2}{2m} \left[ \left( \frac{\partial \Psi}{\partial x} \frac{\partial \Psi^*}{\partial x} \right)_{x=L} - \left( \frac{\partial \Psi}{\partial x} \frac{\partial \Psi^*}{\partial x} \right)_{x=-L} \right]
\]
In Eq. (73b), we have introduced the numerical switch

$$\sigma = \begin{cases} 
0 & \text{Ehrenfest } [1] \\
1 & \text{Alonso et al } [13], \text{De Vincenzo } [15, 16], \text{this study}
\end{cases}$$

(74)

to be able to select between the formulations whose consequences we wish to compare. Of course, Eqs. (48) and (54) remain applicable as such. We can dress the external forces due to the confining walls in Eq. (73b) in a perhaps more physically significant manner by applying the transformation

$$\begin{aligned}
\frac{\partial \Psi}{\partial x} &= \frac{1}{2} \left( \frac{\hbar^2}{m} \frac{\partial^2 \Psi}{\partial x^2} + \frac{\partial \Psi}{\partial x} \right) \\
\end{aligned}$$

(75)

according to which, and taking into account the confinement boundary conditions, we can rewrite Eq. (73b) as

$$\begin{aligned}
\frac{d \langle \rho \rangle}{dt} &= \int_{-L}^{+L} \Psi^* \left( - \frac{\partial V}{\partial x} \right) \Psi dx + \\
&+ \sigma \cdot \left\{ \left[ \frac{\partial \left( \frac{\hbar^2}{m} \frac{\partial \Psi^*}{\partial x} \right) \right]_{x=L} - \left[ \frac{\partial \left( \frac{\hbar^2}{m} \frac{\partial \Psi^*}{\partial x} \right) \right]_{x=-L} \right\}
\end{aligned}$$

(76)

Equation (76) reveals better than Eq. (73b), we believe, the role of the external forces by clearly identifying the spatial derivative of the probability density as a potential

$$\frac{\hbar^2}{m} \frac{\partial \Psi^* \Psi}{\partial x}$$

whose gradients calculated at the boundaries of the spatial domain characterise the action of the confining walls on the particle. Such forces are switched off in Ehrenfest’s formulation ($\sigma = 0$); however, if $\sigma = 1$ then they impact the macroscopic observable momentum exactly as the force due to the physical potential does. A simple way to push this conflictual situation to stand out with incontestable evidence is to consider the static case in which the initial wavefunction [Eq. (21)] coincides with a pure eigenfunction

$$f(x) = \psi_k(x)$$

(77)

This initial condition presupposes the following sequence of simplifications. Only the coefficient corresponding to the eigenfunction survives ($c_r = \delta_{rk}, c^*_l = \delta_{lk}$) and the wavefunction general solution simplifies to

$$\Psi(x, t) = \exp \left( -i \frac{\epsilon_k t}{\hbar} \right) \psi_k(x)$$

(78)

The macroscopic observable position [Eq. (47)] becomes time-independent

$$\langle x \rangle = \int_{-L}^{+L} \psi_k^* x \psi_k dx$$

(79)
its time derivative [Eq. (48)] vanishes
\[ \frac{d\langle x \rangle}{dt} = 0 \] (80)
and so do the macroscopic observable momentum [Eq. (73a)]
\[ \langle p \rangle = 0 \] (81)
and its time derivative [Eq. (54)]
\[ \frac{d\langle p \rangle}{dt} = 0 \] (82)
The attentive reader may notice that Eq. (53) reduces to
\[ \langle p \rangle = \int_{-L}^{+L} \frac{\hbar}{i} \frac{\partial \psi_k}{\partial x} \psi_k^* dx \] (83)
and perceive an inconsistency between Eqs. (81) and (83); such an inconsistency, however, is only apparent and is quickly removed by Eq. (59d)(c) particularised to the case \( s = r \) because it enforces, for any arbitrary \( r \), the (rather curious) orthogonality condition
\[ \int_{-L}^{+L} \frac{\hbar}{i} \frac{\partial \psi_k}{\partial x} \psi_k^* dx = 0 \] (84)
that, with \( r = k \), realigns Eq. (83) to Eq. (81). Now, what happens to Eq. (73b)? The left-hand side vanishes according to Eq. (82); the right-hand side follows from Eq. (52)(c) with \( s = r = k \)
\[ 0 = \int_{-L}^{+L} \left( -\frac{\partial V}{\partial x} \right) \psi_k dx - \sigma \cdot \frac{\hbar}{2m} \left[ \left( \frac{\partial \psi_k}{\partial x} \frac{\partial \psi_k^*}{\partial x} \right)_{x=+L} - \left( \frac{\partial \psi_k}{\partial x} \frac{\partial \psi_k^*}{\partial x} \right)_{x=-L} \right] \] (85)
in which we have introduced the switch \( \sigma \) for consistency with Eq. (73b). Equation (85) describes the equilibrium between the force due to the physical potential and the external forces; as a consequence of such equilibrium, we macroscopically observe the particle standing at the position given by Eq. (79). Equation (61g) (c) with \( s = r = k \) helps us to go a bit further than Eq. (85) by providing the integral
\[ \int_{-L}^{+L} \left( -\frac{\partial V}{\partial x} \right) \psi_k dx = \frac{\hbar}{2m} \left[ \left( \frac{\partial \psi_k}{\partial x} \frac{\partial \psi_k^*}{\partial x} \right)_{x=+L} - \left( \frac{\partial \psi_k}{\partial x} \frac{\partial \psi_k^*}{\partial x} \right)_{x=-L} \right] \] (86)
so that Eq. (85) reduces to the final form
\[ 0 = (1 - \sigma) \cdot \frac{\hbar}{2m} \left[ \left( \frac{\partial \psi_k}{\partial x} \frac{\partial \psi_k^*}{\partial x} \right)_{x=+L} - \left( \frac{\partial \psi_k}{\partial x} \frac{\partial \psi_k^*}{\partial x} \right)_{x=-L} \right] \] (87)
With a look at Eq. (87), we conclude that everything is consistent if \( \sigma = 1 \); on the other hand, a conflict becomes evident if \( \sigma = 0 \) and the external forces do not either vanish or compensate. In this regard, a numerical test case with a symmetrical potential \( V(x) \) will not serve our purpose because the symmetry will flatten out to zero the right-hand
On Ehrenfest’s theorem

To convince ourselves, it is sufficient to open Pauling and Wilson’s textbook [38] and look at the first four eigenfunctions produced by the uniform potential [Fig. 14-2 (left)] or by the (unconfined) harmonic-oscillator potential [Figs. 11-2 (left) and 11-3 (top)]. In the former case, the external forces compensate because the squares of the slopes coincide

\[ \left( \frac{\partial \psi_k}{\partial x} \frac{\partial \psi_k}{\partial x} \right)_{x=+L} = \left( \frac{\partial \psi_k}{\partial x} \frac{\partial \psi_k}{\partial x} \right)_{x=-L} \]  

while in the latter case the external forces vanish because the slopes vanish

\[ \left( \frac{\partial \psi_k}{\partial x} \right)_{x=\infty} = 0 \]

Thus, a test case with unsymmetrical potential is advisable and, therefore, we have considered an electric charge \( q \) in a uniform electrostatic field \( E \) with potential

\[ V(x) = -qEx \]

This potential satisfies Eq. (3) and is safely beyond the reach of the criticisms discussed in Sec. 1 in connection with that condition. The macroscopic observable

\[ \langle V \rangle = \int_{-L}^{+L} \Psi^* V \Psi \, dx = -qE \langle x \rangle = V \langle x \rangle \]

comes to coincide with the potential as a function of the macroscopic observable position; consequently, and taking in due account the wavefunction normalisation [Eq. (5)], the macroscopically observable force can be expressed as follows

\[ \int_{-L}^{+L} \Psi^* \left( -\frac{\partial V}{\partial x} \right) \Psi \, dx = -\frac{\partial \langle V \rangle}{\partial \langle x \rangle} = qE \]

and Eqs. (73) become

\[ \frac{d\langle x \rangle}{dt} = \frac{1}{m} \langle p \rangle \]  

\[ \frac{d\langle p \rangle}{dt} = -\frac{\partial \langle V \rangle}{\partial \langle x \rangle} - \frac{\hbar^2}{2m} \left[ \left( \frac{\partial \Psi}{\partial x} \frac{\partial \Psi^*}{\partial x} \right)_{x=+L} - \left( \frac{\partial \Psi}{\partial x} \frac{\partial \Psi^*}{\partial x} \right)_{x=-L} \right] \]

We have dimmed the external forces in Eq. (92b) because they are invisible in Ehrenfest’s formulation [Eqs. (2)] and to bring forth the evidence that, with the dimmed terms unseen, not only the macroscopically observable statics/dynamics of the electric charge would comply with the classical-mechanics prescript but also, and more importantly, that quantum mechanics would have really nothing to say in that respect because Eqs. (92) would be in a mathematically closed form that could be integrated in time without any connection whatsoever with the underlying microscopically quantic substrate. Yet, the dimmed terms are undeniably there and, through them, quantum mechanics has its saying; we will find out in next section if and how. Well, it looks like we are settling for a rather attractive test case.
3.9.2. Electric charge in uniform electrostatic field. With the electrostatic potential of Eq. (89), the time-independent Schrödinger equation [Eq. (26)] takes the explicit form

\[-\frac{\hbar^2}{2m} \frac{\partial^2 \psi}{\partial x^2} - qEx \psi = \epsilon \psi\]  

(93a)

that we must integrate with the confinement boundary conditions

\[\psi(-L) = \psi(+L) = 0\]  

(93b)

and the normalisation condition [Eq. (37)]

\[\int_{-L}^{+L} \psi^* \psi \, dx = 1\]  

(93c)

We rephrase the eigenvalue problem by referring the \(x\) coordinate to the semi-length of the one-dimensional box

\[x = \xi \cdot L\]  

(94a)

and by scaling the eigenfunctions

\[\psi \rightarrow \frac{\psi}{\sqrt{2L}}\]  

(94b)

In this way, Eqs. (93) turn into the nondimensional forms

\[-\frac{\partial^2 \psi}{\partial \xi^2} - \alpha \xi \psi = \beta \psi\]  

\[\psi(-1) = \psi(+1) = 0\]  

\[\frac{1}{2} \int_{-1}^{+1} \psi^* \psi \, d\xi = 1\]  

(95)

which include two characteristic numbers

\[\alpha = \frac{2mqEL^3}{\hbar^2}\]  

(96a)

\[\beta = \frac{2mL^2}{\hbar^2} - \epsilon\]  

(96b)

It is rather straightforward to prove from Eqs. (95) that

\[\psi(\xi, -\alpha) = \psi(-\xi, \alpha)\]  

(97)

and, therefore, we concentrate only on the solutions with positive \(\alpha\); they describe the situations in which electric charge and electric field have same sign. For the numerical solution of our mathematical problem, we have utilised a method based on high-order finite differences [39–41] implemented in the code HOFiD_MSP that can solve multiparameter spectral BV-ODE problems; in our calculations we have always utilised 8th-order formulae on a grid composed of 1001 equally spaced points on the interval \([-1, +1]\).

As it is well known, if the electric field is absent \((\alpha = 0)\) then Eqs. (95) produce analytical eigenfunctions

\[\psi_k(\xi) = \sqrt{2} \sin \left[\frac{k\pi}{2} (\xi + 1)\right]\]  

(98)
On Ehrenfest’s theorem

and eigenvalues

\[ \beta_k = \left( \frac{k\pi}{2} \right)^2 \]  

(99)

With Eq. (99) in hand, the dimensional energy levels

\[ \epsilon_k = \left( \frac{k\pi}{2} \right)^2 \frac{h^2}{2mL^2} = \frac{k^2h^2}{8m(2L)^2} \]  

(100)

are easily retrieved from Eq. (96b); to be on the safe side, we have verified Eq. (100) against Eq. (14-7) at page 97 of Pauling and Wilson’s textbook [38] (notation correspondence: \( k \rightarrow n_x; 2L \rightarrow a \)). We have used this analytical solution [Eq. (98)] to validate our numerical method; the outcome of the validation exercise, consisting in the superposition of analytical and numerical calculations for the first four eigenfunctions \((k = 1, 2, 3, 4)\), is illustrated in Fig. 1 and is very satisfactory.

![Graphs showing analytical and numerical calculations for the first four eigenfunctions](image)

**Figure 1.** Validation exercise with the first four eigenfunctions of the analytical solution [Eq. (98)] corresponding to \( \alpha = 0 \).

With the validation test positively passed, we have carried out calculations for the first four stationary states \((k = 1, 2, 3, 4)\) with the electric field switched on at \( \alpha = 10, 100 \).
The eigenvalues are listed in Table 1 as direct output from the calculation (2nd column) and scaled with the numerical factor $4/\pi^2$ (3rd column) in analogy to Eq. (99).

**Table 1.** Eigenvalues, eigenfunctions’ derivatives at the boundaries, and macroscopic observable position for the first four stationary states.

Eigenfunctions and probability densities are shown, respectively, in Figs. 2 and 3. The graphs give ample evidence of how the electric field breaks the symmetries, induces a general rightward ($\alpha > 0$) shift, and makes uneven maxima and minima. Also, its impact on the eigenfunctions’ derivatives at the boundaries, which are of particular importance to us, is evident. Let us rewrite here Eq. (87) in nondimensional form [Eqs. (94)]

$$0 = (1 - \sigma) \cdot \left[ \left( \frac{\partial \psi_k}{\partial \xi} \right)_{\xi=+1} - \left( \frac{\partial \psi_k}{\partial \xi} \right)_{\xi=-1} \right]$$

(101)

When $\alpha = 0$ we can take the derivative of Eq. (98)

$$\frac{\partial \psi_k}{\partial \xi} = \frac{k\pi}{\sqrt{2}} \cos \left[ \frac{k\pi}{2} (\xi + 1) \right]$$

(102)

calculate it at the boundaries

$$\left( \frac{\partial \psi_k}{\partial \xi} \right)_{\xi=-1} = \frac{k\pi}{\sqrt{2}}$$

$$\left( \frac{\partial \psi_k}{\partial \xi} \right)_{\xi=+1} = \frac{k\pi}{\sqrt{2}} \cos(k\pi)$$

(103)
and obtain the analytical verification of Eq. (88a) that we had anticipated on the basis of graphical arguments deduced from Fig. 14-2 (left) in Pauling and Wilson’s textbook [38], also reproduced in our Fig. 1. Thus, Eq. (101) is satisfied regardless of which value the switch $\sigma$ is set to. With due account of Eqs. (94) and Eq. (100), Eqs. (103) allow to retrieve easily the dimensional expression

$$
\frac{\hbar^2}{2m} \left( \frac{\partial \psi_k}{\partial x} \frac{\partial \psi_k}{\partial x} \right)_{x=\pm L} \rightarrow \frac{\hbar^2}{2m} \frac{1}{2L^3} \left( \frac{\partial \psi_k}{\partial \xi} \frac{\partial \psi_k}{\partial \xi} \right)_{\xi=\pm 1} = 2 \frac{\varepsilon_k}{(2L)}
$$

(104)

of the external forces, in agreement with the result obtained by De Vincenzo [15, 16] with a similar calculation. The same expression, as duly mentioned by De Vincenzo, was also proposed by ter Haar [42] (problem 25 at page 5; solution at page 88) although he followed a completely different path. Ter Haar pointed out that and, above all, clearly explained how the expression given in Eq. (104) [corresponding to his Eq. (10) at page 91] “retains its form exactly in classical mechanics”.

When $\alpha \neq 0$, we have calculated the derivatives numerically; they are listed in Table 1. A quick numerical check with the values collected therein shows that the external-force difference in Eq. (101) differs from zero and, therefore, setting the switch
On Ehrenfest’s theorem

Figure 3. Probability density for the first four stationary states of an electric charge in uniform electrostatic field.

to $\sigma = 0$ (Ehrenfest’s mode) brings up an incontrovertible conflict. An additional check of confidence that $\sigma = 1$ is the correct choice is offered by Eq. (86) after we substitute in it the electrostatic potential and then turn to the nondimensional form [Eqs. (94) and Eq. (96a)]

$$\alpha = \frac{1}{2} \left[ \left( \frac{\partial \psi_k}{\partial \xi} \frac{\partial \psi^*_k}{\partial \xi} \right)_{\xi=+1} - \left( \frac{\partial \psi_k}{\partial \xi} \frac{\partial \psi^*_k}{\partial \xi} \right)_{\xi=-1} \right]$$  \hspace{1cm} (105)

Equation (105) is the nondimensional way to say that the electrical force is balanced by the external forces. The right-hand side’s values produced by the numerically obtained derivatives listed in Table 1 are contained in the second column from right in the same table. The match with the values of $\alpha$ is indisputable; as a matter of fact, we were really surprised to see how well those apparently patternless numerically determined values of the external forces comply with the equilibrium dictated by Eq. (105). The verdict ruled by the non-vanishing of the external forces in Eq. (101) and by their compliance with Eq. (105) is that the correct position of the switch [Eq. (74)] is $\sigma = 1$; this is the numerical corroboration of the theory we were looking for.
As a consequence of the equilibrium between the electric force and the external forces, the electric charge does not move and, therefore, does not radiate. It stands quietly at the nondimensional macroscopically observable position [Eq. (79)]

\[
\langle \xi \rangle = \frac{1}{2} \int_{-1}^{+1} \psi_k \xi \psi_k \, d\xi
\]  

(106)

The values produced by Eq. (106) for the first four stationary states are collected in the rightmost column of Table 1. Obviously, the electric-charge equilibrium position always coincides with the center of the box \( \langle \xi \rangle = 0 \) if the electric field is absent \( (\alpha = 0) \); the analytical confirmation is achieved by substituting Eq. (98) in Eq. (106) and executing the integral. In the case \( \alpha = 10 \), the position shifts expectedly to the right \( (\langle \xi \rangle > 0) \) for the ground state \( (k = 1) \) but surprisingly to the left \( (\langle \xi \rangle < 0) \) for the excited states \( (k = 2, 3, 4) \). In the case \( \alpha = 100 \), the values indicate a clear rightward shift for all the considered stationary states. In order to achieve a global and better insight about the influence of the electric field, we have scanned numerically the output of Eq. (106) with \( \alpha \) ranging in the interval \([0, 100]\) and plotted the results in Fig. 4. They confirm that the

Figure 4. Nondimensional macroscopic observable position versus electric field.

position shifts monotonically rightward for the ground state but they also give evidence
of the existence of a leftward-position range (between the minima and the zero level in Fig. 4) for the excited states. This may appear surprising at first sight because it would look like as if, for example, a positive electric charge be repelled by an electric field pointing in the positive direction of the $x$ axis. But we should not both be mislead by our intuition and overlook the fact that the electric force is not the only one present: the electric-charge position [Eq. (106)] is decided by the equilibrium between the electric force and the external forces [Eqs. (85) and (105)].

A similar want of better insight is triggered by the eigenvalues shown in Table 1. With respect to an increase of electric-field intensity, the values reported therein indicate a monotonic decrease for the ground state, the existence of a maximum for the stationary states $k = 2, 3$ and a monotonic increase for the stationary state $k = 4$. The systematic series of calculations with our code HOFiD_MSP, in eigenvalue-only mode, for $\alpha$ ranging in the interval $[0, 100]$ has produced the results shown in Fig. 5. Indeed, each stationary state features a (rather shallow than peaked) maximum eigenvalue. The ground-state maximum eigenvalue corresponds to the absence of the electric field ($\alpha = 0$); then the eigenvalues decrease monotonically as suggested by Table 1. The monotonicity of the

![Figure 5. Nondimensional scaled eigenvalues versus electric field.](image-url)
stationary state $k = 4$ was only apparent.

4. Conclusions

The analysis described in the preceding sections has arisen from the interest to investigate the incompleteness of Ehrenfest’s theorem and the necessity to resolve the doubt regarding whether or not the hermiticity of the hamiltonian is sufficient to make the integral $I_\Omega$ [Eq. (9)] vanish unconditionally and, thus, to permit the simplification of a macroscopic-observable time derivative from Eq. (8) to Eq. (10), a notorious praxis in quantum-mechanics textbooks. We have carried out the study by considering the simple quantum system “particle in a one-dimensional box”. We have emphasised the key role of the boundary conditions [Eqs. (22)] to certify a given operator as hermitean and have shown explicitly that, the hermiticity of the hamiltonian notwithstanding, the integral $I_\Omega$ may not vanish [Eqs. (41) and (49)] necessarily; for a given operator, the final word in that respect is left to the boundary conditions, once again. The immediate consequence is that the claimed generality of the Ehrenfest’s formulation [Eqs. (2)] of his famous theorem decays because additional boundary terms [Eqs. (43) and (51)] appear. In this regard, we have systematically and consistently retrieved the same expressions [Eq. (45) and Eq. (51)(c)] of the boundary terms already obtained by Hill [11], Alonso et al [13,14] and De Vincenzo [15,16]. We have investigated and discussed the physical meaning of the boundary terms for the (c) and (p) cases in Sec. 3.8. With regard to the time derivative of the macroscopic observable momentum [Eq. (51)(c)], the boundary terms turn out to be the external forces due to the confining walls and to have the same legitimate status as the macroscopic observable force deriving from the physical potential $V(x)$. With the specific purpose in mind to let external-force effects stand out, we have considered the stationary-state circumstance in which the initial wavefunction coincides with an eigenfunction [Eq. (77)]; in such a simplified situation, the particle should be macroscopically observed resting at a position [Eq. (79)] decided by the equilibrium between the macroscopic observable force due to the physical potential and the external forces [Eq. (85)]. Ehrenfest’s formulation [Eqs. (2)] does not account for the establishment of such an equilibrium of forces and would, therefore, raise a conflict in the relevant equations [$\sigma = 0$ in both Eq. (85) and Eq. (87)]. We have complemented and corroborated the theoretical findings with a numerical exercise in which the particle is an electric charge subjected to a uniform electrostatic field [Eq. (89)]. We have solved numerically the nondimensional hamiltonian eigenvalue problem [Eq. (95)] governed by one main characteristic number [Eq. (96a)] for the first four stationary states and obtained corresponding eigenvalues (Table 1) and eigenfunctions (Fig. 2) for three electric-field situations ($\alpha = 0, 10, 100$). We have illustrated the dependence of electric-charge macroscopic observable position (Fig. 4) and eigenvalues (Fig. 5) on electric field. The numerical results retrieved for the eigenfunctions’ derivatives at the boundaries (Table 1) prove beyond any doubt the indispensability [$\sigma = 1$ in Eq. (85), Eq. (87) and Eq. (101); see also Eq. (105)] of the external-force presence in Eq. (73b)
and the incompleteness of Ehrenfest’s theorem in the formulation he gave [Eqs. (2)].

Acknowledgments

We wish to thank B. Sutcliffe (Université Libre de Bruxelles) and S. De Vincenzo (Universidad Central de Venezuela, Caracas) for their availability to discuss aspects of the subject dealt with in this work and, above all, for their useful advises. We also wish to thank A. R. Plastino (Universidad Naciónal de Buenos Aires) for his insightful comments because they have broadened our perspective and, consequently, our understanding of the subject matter has definitely benefited by further thinking and elaboration induced by them.
