Abstract

Introduction To describe the incidence and relative survival in women with epithelial ovarian cancer (EOC) in a population-based cohort in the four decades after diagnosis. EOC is the major pathological type of all ovarian cancers, however, there is limited information on changes of long-term survival in EOC in the four decades.

Methods We extracted the incidence and relative survival data from Surveillance, Epidemiology, and End Results (SEER) registries to assess epidemiological changes of patients with EOC from 1974 to 2013. The survival disparities of patients with EOC among four decades, age, race, and socioeconomic status (SES) were performed by Kaplan-Meier curves.

Results The overall incidence of EOC gradually declined from 11.4 to 9.0 per 100,000 in the past four decades. The median survival increased from 27 months in the first decades to 48 months in the fourth decade, with 5-year relative survival rate (RSR) improving from 32.3% to 44.3% in the same period. However, the median survival differences increased from 11 months to 18 months between Whites and Blacks and increased from 7 months to 12 months between low-poverty group and high-poverty group respectively over the past four decades.

Discussion This study indicated that the incidence and RSR of EOC patients had improved in the past four decades. But the survival gap between different races and SES gradually widened. More importantly, this study will promote the improvement of health care system and clinical management to erase the survival differences in SES groups and races identified in this study, thereby optimize the clinical outcome.

Background

Ovarian cancer is the major lethal cause of women with gynecologic cancer, with an estimated 22,530 new cases being diagnosed and 13,980 death cases of ovarian cancer around the world in 2019\textsuperscript{1}. Due to lack of specific symptoms and early detection methods, most patients with ovarian cancer had developed to advanced stage (Stage III and IV) when they were diagnosed, which have an unsatisfactory prognosis in spite of immediate and aggressive treatment\textsuperscript{2}. The five-year survival of patients with advanced-stage ovarian cancer is approximately 30%, with increased risk of metastasis.
and recurrence\textsuperscript{2}. Although the treatment of cancer has been greatly improved, including chemotherapy, radiotherapy, targeted therapy and biological therapy, the survival haven’t been found improved significantly, with 5-year survival rate below 45%, indicating that an urgent need to understand the causes and analysis epidemiological trends of ovarian cancer, which could help improve clinical management and treatment outcomes.

Epithelial ovarian cancer (EOC) is the main pathological type of all ovarian cancers, accounting for approximately 90\%\textsuperscript{3}. However, previous epidemiological information for EOC was limited, therefore, we performed a comprehensive population-based analysis to clarify the prognostic significance of age, race and socioeconomic status (SES) in the incidence and relative survival of EOC patients. Data in 1974–2013 from the US Surveillance, Epidemiology and End Results (SEER) cancer registry program, were used to assess the association of incidence and relative survival with age, race and SES.

Recently growing evidence showed that the health care system appeared increasingly distinct racial and SES differences in various aspects of the United States, which has been focused by health care politicians\textsuperscript{4–6}. Thus, the aim of the study was not only to examine population-level changes over time in incidence and long-term relative survival for patients with EOC diagnosed among 1974–2013, but also to evaluate the relative survival differences between different race and SES in EOC.

Methods
Data source
All data on patients with primary invasive EOC were obtained from SEER program during 1974–2013. Data on incidence and relative survival rate, respectively, were extracted from the original nine and 18 SEER sites.

Stratified Ovarian Cancer Cases Over The Past Three Decades
We utilized SEER*Stat version 8.3.5 to obtain and analyze the incidence and relative survival data. Patient inclusion criteria were based on the ICD-O-3 (International Classification of Diseases for Oncology, 3rd edition) and WHO 2008 site code C56.9\textsuperscript{7} from 1974 to 2013. We excluded EOC cases diagnosed by autopsy or reported only on a death certificate. In this study, variables included year of
diagnosis, age, race and SES. Data on incidence and relative survival data between 1974 and 2013 were analyzed after being divided by four decades. According to age, the patients were divided into four groups (0-44, 45-54, 55-69, 70 + years), and race was classified as White, Black, and Other (American Indian/Alaska Native, Asian/Pacific islander). The county poverty rate was used to define area SES, which was divided into three levels using the National Cancer Institute monograph: < 10% (low-poverty areas), 10%-19.99% (medium-poverty areas), and ≥ 20% (high-poverty areas). 

Statistical analysis
Incidence was expressed per 100,000 population and age-adjusted to 2000 U.S. standard population. The Kaplan-Meier log-rank test was performed to compare the survival differences between subgroups of each variable and p value < 0.01 was considered to be statistically significant.

Results
Incidence trend of EOC between 1974 and 2013
Total 53,269 patients with EOC were diagnosed among 1974–2013 from original 9 SEER registry sites. The overall incidence of EOC gradually decreased from 11.4 to 9.0 per 100,000 in the four decades. And all age groups also were found to present a similar downward incidence trend, with the most significant decline in the 0–44 age group, which decreased by 33.3%, from 2.4 to 1.8 per 100,000 (Fig. 1a, 1b, Supplementary Table S1).

Over the past four decades, the incidence of EOC in three race subgroups had declined over time. A similar incidence of EOC was observed between Blacks and Others, with Whites having the highest incidence in the past four decades. However, as EOC incidence in Whites declined faster in the four decades, the incidence gaps among the three race subgroups become narrowing (Fig. 1c).

The incidence of EOC had declined in the three subgroups of SES, with the lowest incidence in the high poverty group over the past four decades (from 9.5 in 1974–1983 to 7.1 in 2004–2013). In the past four decades, the low poverty group showed the highest incidence of 11.8, 12.0, 10.7, 9.0 per 100,000 each decade. In addition, the incidence of medium poverty group was between low-poverty group and high-poverty group (Fig. 1e).

Changes Of Relative Survival In Eoc During 1974–2013
Totally 93,639 EOC cases were obtained from 18 SEER sites in the past four decades. There was an
improvement in median survival of EOC patients (from 27 months in the first decades to 48 months in the fourth decade) as well as relative survival rate (RSR) and survival time for patients with EOC in the four decades (Table 1, Fig. 2a). The 5-year RSR in 1994-2003 was higher than that in 1984-1993 and 1974-1983 (41.3% in 1994-2003 vs 34.4% in 1984-1993 vs 32.3% in 1974-1983, p < 0.0001), and even higher in 2004-2013 (44.3% vs 41.1%, p < 0.0001) with a significant increase by 37.5% compared to the first decade. The trend of survival improvement was also observed in the RSR of 1 year, 2 year and 10 year. Furthermore, improvement in survival of all age groups was demonstrated by Kaplan-Meier survival analysis with statistical significance over four decades (p < 0.0001; Fig. 2b).
Table 1
Relative survival rates of epithelial ovarian cancer patients during the periods of 1974–1983, 1984–1993, 1994–2003, and 2004–2013 at eighteen SEER sites. Data are mean ± standard error of the mean, with number of patients in parentheses.

Abbreviations: Mo, month; RS, relative survival; SEM, standard error of the mean.
*p < 0.01, **p < 0.001, and ***p < 0.0001 for comparisons with the preceding decade.

Additionally, the survival of all race subgroups improved, with the 5-year RSR of Whites the most significant improvement, increasing by 40.56%, from 31.8 to 44.7 over four decades. In the four decades, the highest survival rate was seen in Others, and Whites showed higher survival compared to Blacks. The 5-year RSR survival difference between Whites and Black widened in 1984–1993.
(34.3% vs 28.4%) and greatly become widener in the last two decades (41.3% vs 30.8% in 1994–2003 and 44.7% vs 30.9 in 2004–2013). A similar tendency of survival difference was also observed over time in 10-year RSRs (Fig. 3a, Table 2).

Abbreviations: Mo, month; RS, relative survival; SEM, standard error of the mean.
*p < 0.01, **p < 0.001, and ***p < 0.0001 for comparisons with the White group.

When survival time of SES subgroups was analyzed, it was showed that the RSR of low-poverty group was the highest while that of high-poverty group was the lowest. Over the past four decades, the survival time of all SES subgroups had improved, but over time, the survival gaps between low-poverty group and high-poverty group become widener and widener. For example, in 1984–1993, the 5-year RSR of low-poverty group and high-poverty group was 35.1% vs 32.5% respectively, and the gap between 1994–2003 and 2004–2013 increased to 6.2% and 7.8%. The 10-year RSR was also observed the similar survival difference tendency (Fig. 3b, Supplementary Table S2).

Distributions of SES varied among different races. Most Whites were defined as low-poverty while most Blacks were defined as high- and medium-poverty (Supplementary Figure S1). In fact, the difference in survival between Whites and Blacks partially reflected the difference in survival between various SES subgroups. In the first decade, the median survival of Whites was 27 months higher than...
that of Blacks for 16 months, and the difference in survival in the fourth decade increased significantly to 18 months ($p < 0.0001$; Fig. 4a). Similarly, compared with the high-poverty group, the survival advantage of the low-poverty group was found, and the median survival gap kept widening and increased from 7 months to 12 months over time. In addition, Kaplan-Meier survival analysis showed significant differences among three SES subgroups in the past four decades (Fig. 4b).

**Discussion**

It was observed that the overall incidence of patients with epithelial ovarian cancer (EOC) declined from 11.4 to 9.0 per 100,000 in the four decades from 1974 to 2013. An improvement of EOC median survival rose from 27 months to 48 months, and 5-year RSR improved from 32.3–44.3% in the same period. However, the median survival differences increased from 11 months to 18 months between Whites and Blacks and increased from 7 months to 12 months between low-poverty group and high-poverty group respectively over the past four decades.

It was showed that the incidence of EOC dropped by 21.0% from 11.4 to 9.0 per 100,000 in the past four decades. The trend of declining incidence was also found in all age groups. EOC patients had an improvement in median survival, and the 5-year RSR grew from 32.3–44.3% in the four decades. Despite absence of effective and specific screening methods in EOC, the improved medical care and the concept of early detection and early treatment of diseases widely spread among the population, and people are more actively involved in medical interaction, which greatly reduces the incidence of EOC. More importantly, advances in modern imaging techniques, modified surgical methods, a combination of multiple chemotherapy and targeted antitumor schemes as well as individualized precise treatment mode, have greatly improved the survival of patients with EOC.

In the four decades, despite Whites showed the highest incidence, the incidence gap become narrowing between Whites and Blacks over time as a result of a markedly rapid decline of incidence in Whites. Furthermore, it was demonstrated that Whites had an advanced survival, with higher 5-year and 10-year RSRs than Blacks, what’s more important, the RSR gap grew widening between Whites and Blacks. Previous studies suggested that black patients with EOC tended to have a delayed treatment or be unlikely to receive standard-of-care treatment including chemotherapy and surgery.
That was closely related to the survival in EOC, which led to a poor prognosis in black patients\textsuperscript{18}. Taken together, an urgent need required to improve the clinical treatment management and health care in black patients with EOC.

Furthermore, incidence of low-poverty group was the highest while that of high-poverty group was the lowest. Additionally, higher RSR was observed in the low-poverty group and the gap in survival between low- and high-poverty groups widened over time especially in the last decade. Prior studies indicated that SES was associated with cultural beliefs, insurance payer status and social support, which impacts the access to healthcare\textsuperscript{19, 20}. And high all-cause mortality closed correlated with less social support\textsuperscript{21, 22}. Moreover, the availability to better healthcare and medical consultation significantly affect treatment and survival of EOC\textsuperscript{19, 23}. When classified by SES, Blacks were found to be inferior to Whites in finance. Financial disadvantage is thought to keep blank patients away from medical counseling and treatment in the early stages of the disease. Therefore, the difference in SES between white and black patients with EOC may partly explain the changes in incidence and survival between them.

There were some limitations in this study. Although a large number of EOC patients were collected from the SEER program to analyze the incidence, survival and their tendencies over the past four decades, this study remained limited due to the result partly reflected the selected SEER sites and was not applicable to other geographic locations. Besides, the study might also be influenced by misclassification and variation of SES within and among counties\textsuperscript{10, 11}. Furthermore, histological and therapeutic data were not analyzed in the study, which may affect the incidence and survival of EOC patients.

Conclusions
In conclusion, our study showed that the incidence and RSR of EOC patients had improved in the past four decades. But with passage of time, the survival gap between different races and SES gradually widened. What’s more important, this study will promote the improvement of health care system and clinical management to erase the survival differences in SES groups and races identified in this study,
and thereby to optimize the clinical outcome of patients with EOC.

Figures

Figure 1

Summary incidences of patients diagnosed as epithelial ovarian cancer (EOC) from 1974 to 2013 at the original nine SEER sites. Incidence (a), and number (b) of EOC cases are shown by age group (total and ages 0-44, 45-54, 55-69, and 70+ years) and calendar period. Incidence (c,e) and number (d,f) of EOC cases are grouped by race and SES, respectively.
Figure 2

Trends in 10-year relative survival rates (a) and Kaplan-Meier survival analysis (b) for patients with EOC at 18 SEER sites in 1974-1983 (orange), 1984-1993 (blue), 1994-2003 (purple) and 2003-2012 (black) respectively according to age group (total and ages 0-44, 45-54, 55-69, and 70+ years) and calendar period.
Figure 3

1-year, 5-year and 10-year relative survival rates (RSR) according to race (a) including White (orange), Black (blue) and Others (black), and SES/county-level poverty rates (b) in Low-poverty (orange), Medium-poverty (blue) and High-poverty (black) for patients with EOC at 18 SEER sites from 1974 to 2013.
Figure 4

Kaplan-Meier survival analysis according to race (a) including White (orange), and Black (blue) and Others (black), and SES/county-level poverty rates (b) in Low-poverty (orange),
Medium-poverty (blue) and High-poverty (black) for patients with EOC at 18 SEER sites from 1974 to 2013.
