Emergence of two *Escherichia coli* strains co-harboring *mcr-1* and *bla*<sub>NDM</sub> in fresh vegetables from China

**Background:** The concurrence of *mcr* and carbapenemase genes among *Enterobacteriaceae* has been a great clinical concern. In our study, we aimed to investigate the prevalence of *mcr*-positive carbapenem-resistant *Enterobacteriaceae* (CRE) in fresh vegetables and shed light on the possibility of transmission of *mcr*-positive CRE via fresh vegetables.

**Methods:** In this study, 712 fresh vegetable samples from 10 provinces in China were collected between May 2017 and Dec 2018 and were screened for *mcr* and carbapenemase genes. Antibiotic susceptibilities for isolates co-harboring carbapenemase genes and *mcr* were determined by an agar dilution or a broth microdilution method. Pulsed-field gel electrophoresis (PFGE) and multilocus sequence typing (MLST) analysis were also performed. Transferability of the carbapenemase/*mcr*-bearing plasmids was determined by conjugation, replicon typing and S1-PFGE-Southern blotting. The sequences of these plasmids were analyzed by using whole-genome sequencing with Illumina Hiseq platform.

**Results:** Two *E. coli* isolates concomitantly carrying *mcr-1* and *bla*<sub>NDM-5,9</sub> from leaf rape and spinach, respectively, were found and both isolates showed multidrug resistance. Notably, *mcr-1*-positive 690 harboring *bla*<sub>NDM-5</sub> and 701 carrying *bla*<sub>NDM-9</sub> belonged to ST156 and ST2847, respectively, similar to the prevalent MLST types of *E. coli* co-carrying *mcr-1* and *bla*<sub>NDM</sub> from avian in our previous study. *mcr-1* was on ~33-kb IncX4 plasmid or ~60-kb IncI2 plasmid, while *bla*<sub>NDM-5,9</sub> was on ~46-kb IncX3 plasmid or ~120-kb untypable plasmid. The plasmids were highly similar to those from animals and clinical patients reported in various countries.

**Conclusion:** *E. coli* isolates concomitantly carrying *mcr-1* and *bla*<sub>NDM-5,9</sub> in fresh vegetables may serve as a direct source of pathogens in humans, and such discovery in fresh vegetables emphasizes the importance of prompt surveillance and intervention in limiting the spread of *E. coli* co-carrying *bla*<sub>NDM</sub> and *mcr-1*. To our knowledge, this is the first report of *Enterobacteriaceae* co-carrying *bla*<sub>NDM</sub> and *mcr-1* in fresh vegetables.

**Introduction**

With the increasing carbapenem consumption in the past two decades, unprecedented global increase has been observed in the populations of carbapenem-resistant *Enterobacteriaceae* (CRE), posing colistin as the last therapeutic resort for the treatment of such organism. However, the efficacy of the drug has been challenged by the emergence of mobilized colistin resistance (*mcr*) genes. Of great clinical concern is the concurrence of *mcr* and carbapenemase genes among *Enterobacteriaceae*. In fact, *mcr* has been found in CRE isolates from food animals<sup>2</sup> and humans,<sup>3–6</sup> around the world, especially in China. High prevalence of *mcr*-positive CRE isolates has been found among...
Consumption of fresh vegetables has increased over the recent years, because vegetables can provide essential components for humans. However, fresh vegetables eaten raw have been linked with outbreak of foodborne diseases and have often served as resistance gene “reservoirs”. For example, cephalosporin-resistant Enterobacteriaceae were found on 5.2% of the 1216 vegetables obtained from Dutch stores during 2012 and 2013. About 25.4% of the 169 vegetables imported from the Dominican Republic, India, Thailand and Vietnam in 2014 harbored one or more extended-spectrum-beta-lactamase-producing Enterobacteriaceae.

Recently, mcr-positive isolates have been also found in one lettuce sample in Portugal and in two imported vegetable samples in Switzerland. In China, 9 of the 916 vegetables (0.98%) sampled in Guangzhou carried mcr-1, while 19 of the 528 fresh vegetables (3.60%) were found to harbor mcr-1-positive isolates in our previous report. In addition, CRE isolates were also sporadically found in fresh vegetables, including one blaOXA-181-positive Klebsiella varicola in Switzerland, three blaOXA-181-positive K. pneumoniae in Algeria, one E. coli co-harboring blaqNDM-1 and blaqKPC-2 in China, and twelve isolates in our previous study in China. All these findings suggest that Enterobacteriaceae-producing carbapenemases and mcr-positive isolates might have emerged and distributed in fresh vegetables around the world, especially in China. However, isolates co-harboring mcr and carbapenemases-encoding genes have not been isolated in those previous studies. Considering the widespread of mcr and carbapenemases-encoding genes in China, it is crucial to identify mcr-positive CRE in fresh vegetables. In this study, we identified two mcr-positive E. coli strains producing NDM-5/9, recovered from fresh vegetables in China and the characteristics of resistance plasmids were also analyzed.

Materials and methods

Samples and identification of Enterobacteriaceae co-harboring mcr and carbapenemases genes

Seventeen different types of fresh vegetables from 72 supermarkets and farmer’s markets in 29 cities or districts of 10 provinces (Shandong, Shanghai, Beijing, Hubei, Henan, Heilongjiang, Yunnan, Tianjin, Shanxi and Jiangsu) in China were purchased between May 2017 and December 2018. In total, 712 fresh vegetable samples were collected, including cucumber (n=125), tomato (n=114), romaine lettuce (n=76), curly endive (n=53), green pepper (n=50), coriander (n=50), leaf rape (n=49), spinach (n=49), mungbean sprouts (n=35), chili pepper (n=28), leaf lettuce (n=20), soybean sprouts (n=18), pakchoi (n=17), garland chrysanthemum (n=10), carrot (n=9), green shallots (n=5) and eggplant (n=4). These samples were processed with Mueller-Hinton (MH) broth co-harboring vancomycin (8 mg/L), colistin (2 mg/L) and meropenem (1.0 mg/L) to select Enterobacteriaceae carrying both carbapenemase and mcr genes using the similar protocol as previously reported. The MH broth with survived bacteria was diluted in series of 1:10 and 100 μL appropriate dilution was spread onto MH agar plates supplemented with both colistin (2 mg/L) and meropenem (1.0 mg/L). Presumptive Enterobacteriaceae colonies on the MH plate were selected for screening the carbapenemase-encoding genes (blaNDM, blaKPC, blalMP, blavIM, blaspM, blAAIM, blaDIM, blagIM, blalSIM, blabIC and blaoXA-48) using primers previously described, and the presence of mcr (mcr-1, mcr-2, mcr-3, mcr-4, mcr-5, mcr-6, mcr-7 and mcr-8) was also determined. mcr-positive isolates carrying carbapenemase-encoding genes were identified by rpoB sequence analysis.

Antimicrobial susceptibility testing

Susceptibility testing to 17 antimicrobial agents was determined by the agar dilution method according to the Clinical and Laboratory Standards Institute (CLSI) criteria. The 17 antimicrobial agents were the following ones: cefotaxime, cefotiorf, meropenem, ampicillin, enrofloxacin, ciprofloxacin, levofloxacin, nalidixic acid, streptomycin, amikacin, gentamicin, kanamycin, doxycycline, tetracycline, tigecycline, florfenicol and fosfomycin. The results except tigecycline were interpreted according to the CLSI breakpoints. The MIC method for colistin and breakpoints for colistin and tigecycline were recommended by the 2017 EUCAST (http://www.eucast.org/clinical_breakpoints/).

MLST and PFGE typing

MLST of the E. coli isolates carrying both carbapenemase and mcr genes in this study was performed to compare with such isolates of other origins. Clonal relationships of isolates in this study and those with the same MLST types from other sources were also investigated by PFGE using XbaI enzyme as previously described. The XbaI-digested DNA of Salmonella Braenderup strain H9812 was used as a reference.
Plasmid conjugation and incompatibility typing

Plasmid conjugation experiment was performed between the mcr-positive isolates carrying carbapenemase and streptomycin-resistant recipient E. coli C600 using the broth-mating method.\(^\text{30}\) mcr-positive transconjugants were selected on eosin methylene blue agar plates containing both streptomycin (2000 mg/L) and colistin (2 mg/L), while MacConkey agar plates supplemented with both streptomycin (2000 mg/L) and meropenem (0.8 mg/L) were used to select transconjugants with carbapenemase genes. Antimicrobial susceptibility testing and PCRs mentioned above were subsequently performed to confirm the transconjugants, followed by Enterobacterial repetitive intergenic consensus PCR as previously described.\(^\text{31}\) Incompatibility (Inc) groups of plasmids within the transconjugants were assigned by the PCR-based replicon typing method,\(^\text{32}\) and the IncX and IncI2 replicons were also detected as previously described.\(^\text{33,34}\)

Plasmid analysis

To analyze the location of mcr and carbapenemase genes, S1 nuclease-PFGE and Southern Hybridization blot were performed twice on the transconjugants and their donors. E. coli C600 lacking plasmid was used to confirm the specific for mcr or carbapenemase gene probe. To determine whether the bla\(_{\text{NDM}}/\text{mcr-1}\)-bearing plasmids in this study were similar to the reported plasmids of other origins, total genomic DNA (including the chromosome and corresponding plasmid) from the two mcr-1-positive transconjugants and two bla\(_{\text{NDM}}\)-positive transconjugants were extracted and sequenced using Illumina HiSeq PE150, respectively. After assembling the sequence reads and cleaning out E. coli C600 chromosomal DNA sequences, plasmid contigs were obtained. All plasmids in this study were then subjected to PlasmidFinder 2.0 (https://ege.cbs.dtu.dk/services/PlasmidFinder/) and ResFinder 3.1 (https://ege.cbs.dtu.dk/services/ResFinder/) to analyze the plasmid replicons and antimicrobial resistance genes, respectively. Functional annotation was performed using the NCBI Prokaryotic Genome Annotation Pipeline server, and the BLASTn implemented in software BRIG was used for sequence comparison.\(^\text{35}\)

Results and discussion

Among the 712 fresh vegetable samples collected in 10 provinces from China in this study, two isolates from leaf rape and spinach in two supermarkets of Shandong province, respectively, carried both bla\(_{\text{NDM-5/9}}\) and mcr-1. To our knowledge, this is the first report of isolates co-carrying bla\(_{\text{NDM-5/9}}\) and mcr-1 in fresh vegetables.

The two isolates were designated 690 and 701 here. rpoB sequence analysis showed that both isolates were E. coli. Isolate 690 concomitantly harbored bla\(_{\text{NDM-5}}\) and mcr-1, while 701 carried both bla\(_{\text{NDM-5}}\) and mcr-1 (Table 1). Both isolates showed resistance to all beta-lactams, tetracyclines, fluoroquinolones, fosfomycin and colistin tested, which were therapeutic agents in clinics in many countries.\(^\text{36}\) Notably, both isolates remained susceptible to amikacin and tigecycline, similar to the E. coli isolates producing both NDM and MCR-1 from humans in China.\(^\text{9}\)

MLST analysis showed that isolates 690 and 701 belonged to ST156 and ST2847, respectively. ST156 and ST2847 were also found in E. coli isolates co-carrying mcr-1 and bla\(_{\text{NDM}}\) from avian in Shandong of China in 2015, in our previous study,\(^\text{12}\) suggesting that the MCR-1-NDM producers in vegetables might have originated from animals because vegetables might be fertilized with manure and wastewater from livestock. In fact, the final effluent applied to farmland in the piggery wastewater treatment system in China has been proved to contain considerable amounts of bla\(_{\text{NDM}}\) and mcr-1,\(^\text{37}\) which will further support our hypothesis. We then performed PFGE using XbaI enzyme to compare the clonal relationships of isolates in this study and isolates of ST156 and ST2847 types from avian we previously reported.\(^\text{12}\) The results showed that the ST156 isolate 690 was different from the five ST156 isolates from avian, and isolate 701 of ST2847 was also different from the two ST2847 isolates of avian origin (Figure 1), suggesting that such isolates in vegetables in this study were not directly derived from the avian feces we studied previously and more E. coli isolates co-carrying mcr-1 and bla\(_{\text{NDM}}\) from other animal farms should be investigated in the future. Notably, ST156 type of E. coli isolates producing NDM-5 and isolate carrying mcr-1 were also found in human from China in 2016\(^\text{9}\) and human from Brazil in 2016,\(^\text{38}\) respectively, while ST2847 E. coli isolated from a patient in Hong Kong in 2004 was found to carry both bla\(_{\text{CTX-M-65}}\) and fosA3.\(^\text{39}\) Thus, the presence of ST156 and ST2847 E. coli isolates producing both NDM-5/9 and MCR-1 in vegetables still represents a threat to human health.

For both isolates, we obtained two different transconjugants harboring mcr-1 or bla\(_{\text{NDM-5/9}}\), respectively (Table 1), fosA3, conferring resistance to fosfomycin, was found in
### Table 1 Characteristics of the two E. coli strains 690 and 701 from fresh vegetables and their transconjugants with plasmids either harboring mcr-1 or blaNDM-5/9

| Strain   | Resistance genes     | MICs (μg/mL) | Resistance profiles                                                                 | Plasmids carrying mcr-1 or blaNDM in transconjugants |
|----------|----------------------|--------------|-------------------------------------------------------------------------------------|------------------------------------------------------|
|          |                      | COL | MEM | CTX | FOS | Replicon type | Size (kb) |
| 690      | mcr-1, blaNDM-5, fosA3 | 16  | >16 | >64 | >256 | MEM, CT, CTX, AMP, COL, DOX, TET, GEN, KAN, NAL, ENR, LEV, CIP, FOS, FFL |                                        |
| COL690   | mcr-1                | 16  | 0.125 | 0.031 | 4    | COL, STR                     | X3 | ~66 |
| MER690   | blaNDM-5             | 0.25 | >16 | >64 | 8    | MEM, CT, CTX, AMP, STR       | X3 | ~66 |
| 701      | mcr-1, blaNDM-9, fosA3 | 16  | >16 | >64 | >256 | MEM, CT, CTX, AMP, COL, DOX, TET, GEN, STR, NAL, ENR, LEV, CIP, FOS, FFL |                                        |
| COL701   | mcr-1                | 16  | 0.125 | 0.031 | 4    | COL, STR                     | 12 | ~60 |
| MER701   | blaNDM-9, fosA3      | 0.25 | >16 | >64 | >256 | MEM, CT, CTX, AMP, FOS, STR, | UT | ~110 |
| C600     |                      | 0.25 | 0.125 | 0.031 | 4    | STR                           |          |

**Abbreviations:** AMP, ampicillin; CTX, cefotaxime; CTF, ceftiofur; MEM, meropenem; COL, colistin; GEN, gentamicin; KAN, kanamycin; STR, streptomycin; CIP, ciprofloxacin; LEV, levofloxacin; ENR, enrofloxacin; NAL, nalidixic acid; DOX, doxycycline; TET, tetracycline; FFL, florfenicol; FOS, fosfomycin; UT, untypable; C600, recipient strain in the conjugation experiment.

### Figure 1 XbaI-PFGE patterns of isolates in this study and isolates of ST156 and ST2847 types co-carrying mcr-1 and blaNDM from avian.

blaNDM-9-positive transconjugants MER701 using primers described previously, while no other resistances were co-transferred with colistin/meropenem resistance in the other 3 transconjugants. Interestingly, there were additional bigger bands marked with arrows in all 4 transconjugants and some donors in the S1-PFGE (Figure 2A and C) and these bands could be also hybridized with the corresponding mcr-1/blaNDM probe (Figure 2B and D), although these experiments were performed several times. These bigger bands were the portion of the mcr-1 blaNDM-5/9-carrying plasmids not exposed to S1 nuclease in the S1-PFGE experiment, according to the findings of the previous study in which the S1-PFGE method was established. Thus, all the 4 transconjugants carried only one plasmid and mcr-1 was located on
IncX4 type plasmid of ~33 kb in COL690, while COL701 carried IncI2 type ~60 kb plasmid harboring mcr-1 (Figure 2C and D). bla<sub>NDM-5</sub> was on IncX3 plasmid of ~40 kb in transconjugant MER690, however, bla<sub>NDM-9</sub> and fosA3 were on the same ~110 kb plasmid which was untypable in MER701 (Figure 2A and B and Table 1).

From the results of plasmid sequences, both mcr-1-bearing plasmids did not carry any other antibiotic resistance
gene besides \textit{mcr-1} and this could account for the resistance phenotypes of transconjugants COL690 and COL701 (Table 1). Comparison of the pCOL690T (accession no. VMKQ00000000) to several previously reported ~33-kb IncX4 plasmids showed that it aligned very well to pCSZ4 (KX711706) (100% in coverage and 99% in identity) from \textit{E. coli} of pork origin in China (Figure 3A). Notably, pCOL690T (VMKQ00000000) from leaf rape in this study was also highly similar to plasmids pKPI5450-MCR-1 (MH715959) from clinical \textit{Klebsiella pneumoniae}.

\begin{figure}[h]

\includegraphics[width=\textwidth]{Figure_3}
\caption{Sequence alignment of \textit{bla}_{NDM}-bearing or \textit{mcr-1}-bearing plasmids. (A) The plasmid pCSZ4 (KX711706) (purple ring) from \textit{E. coli} of pork origin in China was used as a reference to compare with the IncX4 plasmids. The ring light purple, green, red, gray and blue rings represent pKPI5450-MCR-1 (MH715959) from clinical \textit{K. pneumoniae} in Taiwan, pMCR-1-IHT35346 (KX894453) from \textit{E. coli} of pig origin in Germany, pMCR-1-IncX4 (KU761327) from clinical \textit{K. pneumoniae} in China, pHNGDF93 (MF978388) from fish \textit{E. coli} in China, p1106-IncI2 (MG823574) from \textit{E. coli} of chicken, p5CRE51-MCR-1 (CP021176) from clinical \textit{E. coli} in Taiwan, and pCOL690T (VMKQ00000000) in this study, respectively. The outer circle with black arrows signifies annotation of the reference sequence. (B) The plasmid pP111 (KY120365) from \textit{S. typhimurium} in Taiwan was used as a reference to compare with the IncI2 plasmids. The purple, blue, green, red and black rings represent the reference plasmid, pHNGDF93 (MF978388) from fish \textit{E. coli} in China, p1106-IncI2 (MG823574) from \textit{E. coli} of chicken, p1106-NDM (MG825375) from \textit{E. coli} of chicken, pMER701T (VMKQ00000000) in this study, and p92944-NDM (MG838206) from clinical \textit{E. coli} in China, respectively, in this study. The outer circle with black arrows signifies annotation of the reference sequence. (C) The plasmid p977-NDM (MG825382) from \textit{E. coli} of pork origin in China was used as a reference to compare with the IncX3 plasmids. The purple, blue, green, red and gray rings represent the reference plasmid, pHNGDF93 (MF978388) from fish \textit{E. coli} in China, p1106-IncI2 (MG823574) from \textit{E. coli} of chicken, p5CRE51-MCR-1 (CP021176) from clinical \textit{E. coli} in Taiwan, and pCOL701T (VMKQ00000000) in this study, respectively. The outer circle with black arrows signifies annotation of the reference sequence. (D) The plasmid pHYT62-1 (MG196294) from \textit{E. coli} of retail meat in China was used as a reference (purple ring). The blue, dark, and red rings represent plasmid p1106-NDM (MG823575) from \textit{E. coli} of chicken, pMER701T (VMKQ00000000) in this study, and p92944-NDM (MG838206) from clinical \textit{E. coli}, respectively, in China. The outer circle with black arrows signifies annotation of the reference sequence. *represents plasmids in this study.}
\end{figure}
in Taiwan, pmcr1_IncX4 (KU761327) from clinical *K. pneumoniae* in China and pNG14043 (KY120364) from clinical *Salmonella Typhimurium* in Taiwan (Figure 3A). Furthermore, the pCOL690T in the mcr-1-positive NDM-5-producing *E. coli* in this study also showed high similarity to plasmid pMCR-1-IHIT35346 (KX894453) from *E. coli* co-producing OXA-181-carbapenemase and mcr-1 of pig origin in Germany. Plasmid pCOL701T (VMKR00000000) from *E. coli* of spinach in this study aligned well to IncI2 plasmid pP111 (KY120365) (99% in coverage and 100% in identity) from *S. Typhimurium* of pig in Taiwan, pHNGDF93 (MF978388) from fish *E. coli* and p1106-IncI2 (MG825374) from *E. coli* of chicken in China (Figure 3B). Notably, the pCOL701T (VMKR00000000) in NDM-9-producing *E. coli* in this study was also highly similar to pSCRE51-MCR-1 (CP021176) from clinical *E. coli* co-producing NDM-9 and MCR-1 in Taiwan. All these findings suggested that highly similar IncX4 or IncI2 plasmids have disseminated mcr-1 among different *Enterobacteriaceae* species in food and animals around the world, and these plasmids can spread to carbapenemase-producing clinical isolates to threaten human health.

The pMER690T plasmid (VMKS00000000) did not carry any other resistance gene besides *bla*NDM-5 (Figure 3C), and it aligned very well to IncX3 plasmid p977-NDM (MG825382) (100% in coverage and 99% in identity) from *E. coli* of pork origin in China (Figure 3C). Notably, the pMER690T from leaf rape in this study was also highly similar to plasmids pCREC-591_4 (CP024825) from clinical *E. coli* in South Korea, and pJEG027 (KM400601) from clinical *K. pneumoniae* in Australia. Interestingly, the pMER690T (VMKS00000000) in the mcr-1-positive *E. coli* producing NDM-5 in this study also showed high similarity to plasmid pVH1 (CP028705) from *E. coli* of cucumber in China in our previous report, in which only CRE isolates were isolated. Replicon untypable plasmid pMER701T (VMKT00000000) carried resistance genes *fosA3*, *draA12*, *aadA2*, *sul1*, *ble*MBL, *bla*NDM-9r, and *mph(A)*, which were all centralized in the multidrug resistance region (Figure 3D). pMER701T (VMKT00000000) in this study aligned well to plasmids pHNTH02-1 (MG196294) (100% in coverage and 99% in identity), p1106-NDM (MG825375) and p92944-NDM (MG838206), and these three plasmids were from *E. coli* of retail meat, chicken and human, respectively, in China (Figure 3D). These findings suggested that pMER690T- and pMER701T-like plasmids have been disseminated among different *Enterobacteriaceae* species of various origins around the world, especially China.

### Conclusion

In summary, we reported for the first time two clonally unrelated *E. coli* harboring both *bla*NDM-5/9 and mcr-1 in fresh vegetables in China. The dissemination of mcr-1 was mediated by IncX4 or IncI2 plasmid, while *bla*NDM-5/9 was on IncX3 or untypable plasmid. All the plasmids in this study were highly similar to the plasmids from animals and clinical isolates in various countries. The emergence of mcr-1-positive bacteria producing NDM in fresh vegetables is alarming and constitutes a food safety issue. Further investigations are required for monitoring such organisms in fresh vegetables to ensure food safety in China and other countries.
