We present the chiral odd generalized parton distributions (GPDs) for non-zero skewness \( \zeta \) in transverse and longitudinal position spaces by taking Fourier transform with respect to the transverse and longitudinal momentum transfer respectively using overlaps of light-front wave functions (LFWFs) in a simple model. We also present the chiral even GPDs in position space in a phenomenological model.

1 Introduction

The chiral odd generalized transversity distribution \( F_T \) is defined as the off-forward matrix element of the bilocal tensor charge operator. It is a leading twist generalized quark distribution. It is parametrized in terms of four GPDs, namely \( H_T, \tilde{H}_T, E_T \) and \( \tilde{E}_T \) in the most general way \([1, 2, 3]\). The chiral-odd GPDs give various informations on the transversely polarized quark distribution in unpolarized and polarized nucleon. A relation for the transverse total angular momentum of the quarks has been proposed in \([3]\) which involves a combination of second moments of \( H_T, E_T \) and \( \tilde{H}_T \) in the forward limit. In a previous work we have investigated the chiral odd GPDs for a simple spin-1/2 composite particle for \( \zeta = 0 \) in impact parameter space \([4]\). Here, we investigate them for nonzero \( \zeta \). Using an overlap formula in terms of the LFWFs both in the DGLAP (\( n \rightarrow n \)) and ERBL (\( n + 1 \rightarrow n - 1 \)) regions \([5]\), we investigate them in a simple model, namely for the quantum fluctuations of a lepton in QED at one-loop order \([6]\). We generalize this analysis by assigning a mass \( M \) to the external electrons and a different mass \( m \) to the internal electron lines and a mass \( \lambda \) to the internal photon lines with \( M < m + \lambda \) for stability. In effect, we shall represent a spin-\( \frac{1}{2} \) system as a composite of a spin-\( \frac{1}{2} \) fermion and a spin-1 vector boson \([7, 8, 9, 10, 11]\). This field theory inspired model has the correct correlation between the Fock components of the state as governed by the light-front eigenvalue equation, something that is extremely difficult to achieve in phenomenological models. GPDs in this model satisfy general properties like polynomiality and positivity. So it is interesting to investigate the general properties of GPDs in this model. By taking Fourier transform (FT) with respect to \( \Delta_\perp \), we express the GPDs in transverse position space and by taking a FT with respect to \( \zeta \) we express them in longitudinal position space. Qualitative LFWF for the meson and proton can be obtained by taking a derivative of the above LFWF with respect to the mass \([12]\). As a follow up, we present the distribution of partons in impact parameter space in a phenomenological model of the proton GPDs recently proposed in \([10]\).
2 Generalized parton distributions in QED model

We use the parametrization of [3] for the chiral odd GPDs. Following [6, 7], we take a simple composite spin $1/2$ state, namely an electron in QED at one loop to investigate the GPDs. The light-front Fock state wavefunctions corresponding to the quantum fluctuations of a physical electron can be systematically evaluated in QED perturbation theory. The state is expanded in Fock space and there are contributions from $|e^-\gamma\rangle$ and $|e^-e^-e^+\rangle$, in addition to renormalizing the one-electron state. Both the two- and three-particle Fock state components are given in [13]. In the domain $\zeta < x < 1$, there are diagonal $2 \rightarrow 2$ overlaps. Using the overlap formula in [5] we calculate the chiral odd GPDs in this kinematical region. In order to regulate the ultraviolet divergences we use a cutoff $\Lambda$ on the transverse momentum $k^\perp$. $\tilde{H}_T(x, \zeta, t)$ is zero in this model.

We introduce the Fourier conjugate $b^\perp$ (impact parameter) of the transverse momentum transfer $\Delta^\perp$. The GPDs can be expressed in impact parameter space by taking a Fourier transform [3]. In most experiments $\zeta$ is nonzero, and it is of interest to investigate the chiral odd GPDs in $b^\perp$ space with nonzero $\zeta$. The probability interpretation of the impact parameter dependent parton distributions for zero skewness is no longer possible as now the transverse positions of the initial and final protons are different as there is a finite momentum transfer in the longitudinal direction. The GPDs in impact parameter space probe partons at transverse position $|b^\perp|$ with the initial and final proton shifted by an amount of order $\zeta |b^\perp|$. Note that this is independent of $x$ and even when GPDs are integrated over $x$ in an amplitude, this information is still there [14]. Thus the chiral odd GPDs in impact parameter space gives the spin orbit correlations of partons in protons with their centers shifted with respect to each other.

Taking the Fourier transform (FT) with respect to the transverse momentum transfer $\Delta^\perp$ we get the GPDs in the transverse impact parameter space.

\[
E_T(x, \zeta, b^\perp) = \frac{1}{(2\pi)^2} \int d^2\Delta^\perp e^{-i\Delta^\perp \cdot b^\perp} E_T(x, \zeta, t) \\
= \frac{1}{2\pi} \int \Delta d\Delta J_0(\Delta b^\perp) E_T(x, \zeta, t),
\]

(1)
where $\Delta = |\Delta_\perp|$ and $b = |b_\perp|$. The other impact parameter dependent GPDs $\hat{E}_T(x, \zeta, b_\perp)$ and $\mathcal{H}_T(x, \zeta, b_\perp)$ can also be defined in the same way. $\mathcal{H}_T(x, \zeta, b_\perp)$ for a free Dirac particle is expected to be a delta function, the smearing in $|b_\perp|$ space is due to the spin correlation in the two-particle LFWFs. Fig. [1] shows the plots of the above three functions for fixed $\zeta$, the peak of $\mathcal{H}_T(x, \zeta, b_\perp)$ as well as $\hat{E}_T(x, \zeta, b_\perp)$ increases with increase of $x$, however for $E_T(x, \zeta, b_\perp)$ it decreases.

In [15], it was shown that the GPDs are related to a reduced Wigner distribution $W_I(\vec{r}, x)$ by a Fourier transform. For given $x$, this gives a 3D position space picture of the partons inside the proton. If the probing wavelength is comparable to or smaller than the Compton wavelength $\frac{1}{M}$, where $M$ is the mass of the proton, electron-positron pairs will be created, as a result, the static size of the system cannot be probed to a precision better than $\frac{1}{M}$ in relativistic quantum theory. However, in light-front theory, transverse boosts are Galilean boosts which do not involve dynamics. So one can still express the GPDs in transverse position or impact parameter space and this picture is not spoil by relativistic corrections. However, rotation involves dynamics here and rotational symmetry is lost. In [7], a longitudinal boost invariant impact parameter $\sigma$ has been introduced which is conjugate to the longitudinal momentum transfer $\zeta$. It was shown that the DVCS amplitude expressed in terms of the variables $\sigma, b_\perp$ show diffraction pattern analogous to diffractive scattering of a wave in optics where the distribution in $\sigma$ measures the physical size of the scattering center in a 1-D system. In analogy with optics, it was concluded that the finite size of the $\zeta$ integration of the FT acts as a slit of finite width and produces the diffraction pattern.

We define a boost invariant impact parameter conjugate to the longitudinal momentum transfer as $\sigma = \frac{1}{2} b^- P^+$ [7]. The chiral odd GPD $E_T$ in longitudinal position space is given by:

$$E_T(x, \sigma, t) = \frac{1}{2\pi} \int_0^{\zeta_f} d\zeta e^{i\frac{1}{2} P^+ \zeta^- b^-} E_T(x, \zeta, t)$$

$$= \frac{1}{2\pi} \int_0^{\zeta_f} d\zeta e^{i\sigma \zeta} E_T(x, \zeta, t).$$

(2)

Similarly one can obtain $\mathcal{H}_T(x, \sigma, t)$ and $\hat{E}_T(x, \sigma, t)$ as well. Fig. [2] shows the plots of the
Fourier spectrum of the chiral odd GPDs in longitudinal position space as a function of $\sigma$ for fixed $x = 0.5$ and different values of $t$. Both $\tilde{E}_T(x, \sigma, t)$ and $H_T(x, \sigma, t)$ show diffraction pattern as observed for the DVCS amplitude in \[7\]; the minima occur at the same values of $\sigma$ in both cases. However $\tilde{E}_T(x, \sigma, t)$ does not show diffraction pattern. This is due to the distinctively different behaviour of $\tilde{E}_T(x, \zeta, t)$ with $\zeta$ compared to that of $E_T(x, \zeta, t)$ and $H_T(x, \zeta, t)$. $E_T(x, \zeta, t)$ rises smoothly from zero and has no flat plateau in $\zeta$ and thus does not exhibit any diffraction pattern when Fourier transformed with respect to $\zeta$. The position of the first minima in Fig.2 is determined by $\zeta_f$. For $-t = 5.0$ and 1.0, $\zeta_f \approx x = 0.5$ and thus the first minimum appears at the same position while for $-t = 0.1$, $\zeta_f = \zeta_{\text{max}} \approx 0.45$ and the minimum appears slightly shifted. This is analogous to the single slit optical diffraction pattern. $\zeta_f$ here plays the role of the slit width. Since the positions of the minima (measured from the center of the diffraction pattern) are inversely proportional to the slit width, the minima move away from the center as the slit width (i.e., $\zeta_f$) decreases. The optical analogy of the diffraction pattern in $\sigma$ space has been discussed in \[7\] in the context of DVCS amplitudes.

In ref. \[16\] a phenomenologically motivated parametrization of the GPDs $H$ and $E$ are given by fitting the form factor data at zero skewness. Regge type exchanges are incorporated. In Fig.3, we show the plots of the GPD $H$ for u-quarks in impact parameter space as a function of $b_\perp$ and also as a function of $x$.

### 3 Conclusion

In this work, we studied the chiral-odd GPDs in transverse and longitudinal position space. Working in light-front gauge, we used overlap formulas for the chiral odd GPDs in terms of proton light-front wave functions in the DGLAP region. We used a self consistent relativistic two-body model, namely the quantum fluctuation of an electron at one loop in QED. We used its most general form \[6\], where we have a different mass for the external electron and different masses for the internal electron and photon. The impact parameter space representations are obtained by taking Fourier transform of the GPDs with respect to the transverse momentum transfer. When $\zeta$ is non-zero, the initial and final proton are displaced...
in the impact parameter space relative to each other by an amount proportional to $\zeta$. As this is the region probed by most experiments, it is of interest to investigate this. By taking a Fourier transform with respect to $\zeta$ we presented the GPDs in the boost invariant longitudinal position space variable $\sigma$. $H_T$ and $E_T$ show diffraction pattern in $\sigma$ space. We also presented chiral even GPDs in impact parameter space using a recently proposed parametrization.
