SMALL OVERLAP MONOIDS:
THE WORD PROBLEM

Mark.Kambites@manchester.ac.uk

Abstract. We develop a combinatorial approach to the study of semigroups and monoids with finite presentations satisfying small overlap conditions. In contrast to existing geometric methods, our approach facilitates a sequential left-right analysis of words which lends itself to the development of practical, efficient computational algorithms. In particular, we obtain a highly practical linear time solution to the word problem for monoids and semigroups with finite presentations satisfying the condition $C(4)$, and a polynomial time solution to the uniform word problem for presentations satisfying the same condition.

Small overlap conditions are simple and natural combinatorial conditions on semigroup and monoid presentations, which serve to limit the complexity of derivation sequences between equivalent words in the generators. They form a natural semigroup-theoretic analogue of the small cancellation conditions which are extensively used in combinatorial and computational group theory [5]. It is well known that every group admitting a finite presentation satisfying suitable small cancellation conditions is word hyperbolic in the sense of Gromov [2], and in particular has word problem solvable in linear time.

In the 1970s, Remmers [6, 7] developed an elegant geometric theory of small overlap semigroups, using the natural semigroup-theoretic analogue of the van Kampen diagrams extensively employed in combinatorial group theory (see for example [5]). He applied his methods to show that semigroups satisfying sufficiently small overlap conditions have what would now be called linear Dehn function, that is, that the minimum length of a derivation sequence between any two equivalent words is bounded above by a linear function of the word lengths. In theory, it follows immediately that one can test if two words in the generators for such a semigroup are equivalent, by exhaustively searching the (finite) space of all applicable derivation sequences of the given length, to see if any of them transforms one word to the other. However, the number of possible derivation sequences, and hence the time complexity of this algorithm, is exponential in the word length. More sophisticated techniques (such as applications of graph reachability algorithms) are of course applicable, but the problem remains one of searching a space of exponential size, and so we cannot really hope that this approach will lead to a tractable solution for the word problem. The question naturally arises, then, of how hard the word problem really is in these semigroups.
In this paper, we develop a new approach to the study of this important class of semigroups and monoids, along purely combinatorial lines. While our work lacks some of the mathematical elegance of Remmers’ approach — indeed our foundational results are of a rather technical nature and our proofs mainly by case analysis — it has the advantage of permitting a sequential (left-right) analysis of elements, which for computational purposes seems more relevant than a geometric viewpoint. Two computational consequences of the theory we develop are of particular interest. The first is a linear time (on a two-tape Turing machine) algorithm to solve the word problem in any semigroup with a presentation satisfying Remmers’ condition C(4). The second is a polynomial time (more precisely, in the RAM model, quadratic in the presentation length and linear in the word length) solution to the uniform word problem for presentations satisfying the same condition. While the proofs of correctness and of the time complexity bounds for these algorithms are rather technical, the algorithms themselves are quite straightforward to describe and eminently suitable for practical implementation; the author is currently working on an implementation for the GAP computer algebra system [1].

In addition to this introduction, this paper comprises five sections. In Section 1 we briefly recall the definitions of small overlap semigroups and monoids, together with some of their properties, and introduce some notation and terminology which will be used in the rest of the paper. Section 2 establishes some technical, but nonetheless important, combinatorial properties of small overlap monoids, which are then used in Section 3 to give a sequential characterisation of equivalence for two words in the generators of a C(4) presentation. Section 4 shows how this characterisation can be used to develop a linear time algorithm for the solution of the word problem of a fixed small overlap presentation. Finally, in Section 5 we apply our techniques to the solution of the uniform word problem for C(4) presentations; we also observe that one test efficiently whether an arbitrary presentation satisfies the condition C(4).

The relationship of this work to the geometric approach developed by Remmers [6] perhaps deserves a further comment. As already mentioned, our approach to small overlap semigroups is entirely combinatorial and, in its finished state, makes no direct use of Remmers’ geometric machinery. However, the author would most likely never have arrived at this viewpoint without the insight and intuition afforded by Remmers’ approach, and the reader interested in fully understanding the present paper may find it helpful to study also Remmers’ work in parallel. Some of his results have been given a very accessible treatment by Higgins [3], but unfortunately the only complete source still seems to be his thesis [6].

1. Preliminaries

We assume familiarity with basic notions of combinatorial semigroup theory, including free semigroups and monoids, and semigroup and monoid presentations. In all but Section 5 of the paper, which is devoted to uniform decision problems, we assume we have a fixed finite presentation for a
monoid (or semigroup — we shall see shortly that the difference is unimportant). Words are assumed to be drawn from the free monoid on the generating alphabet unless otherwise stated. We write \( u = v \) to indicate that two words are equal in the free monoid, and \( u \equiv v \) to indicate that they represent the same element of the semigroup presented. We say that a word \( p \) is a possible prefix of \( u \) if there exists a (possibly empty) word \( w \) with \( pw \equiv u \), that is, if the element represented by \( u \) lies in the right ideal generated by the element represented by \( p \). The empty word is denoted \( \epsilon \).

A relation word is a word which occurs as one side of a relation in the presentation. A piece is a word in the generators which occurs as a factor in sides of two different relations, or as a factor of both sides of a relation, or in two different (possibly overlapping) places within one side of a relation. To ensure a uniform treatment for free semigroups and monoids, we make the convention that the empty word \( \epsilon \) is always a piece, even if the presentation has no relations.

The presentation is said to satisfy the condition \( C(n) \), where \( n \) is a positive integer, if no relation word can be written as the product of strictly fewer than \( n \) pieces. Thus for each \( n \), \( C(n + 1) \) is a strictly stronger condition than \( C(n) \). We briefly mention another related condition. The presentation satisfies the condition \( OL(x) \), where \( 0 \leq x \leq 1 \) if whenever a piece \( p \) occurs as a factor of a relation word \( R \) we have \( |p| < x|R| \). Notice that if \( n \) is a positive integer, then a semigroup satisfying \( OL(1/n) \) will certainly satisfy \( C(n + 1) \).

The weakest meaningful small overlap condition, \( C(1) \), says that no relation word is a product of zero pieces, that is, that \( \epsilon \) is not a relation word. From this we see that in a small overlap monoid presentation, no non-empty word can be equivalent to the empty word, that is, no non-empty word can represent the identity. It follows that every small overlap monoid presentation is also interpretable as a semigroup presentation, and that the monoid presented is isomorphic to the semigroup presented with an adjoined identity element. For simplicity in what follows we shall focus upon small overlap monoids, but from each of our results one can immediately deduce a corresponding result for small overlap semigroups.

For each relation word \( R \), let \( X_R \) and \( Z_R \) denote respectively the longest prefix of \( R \) which is a piece, and the longest suffix of \( R \) which is a piece. If the presentation satisfies \( C(3) \) then \( R \) cannot be written as a product of two pieces, so this prefix and suffix cannot meet; thus, \( R \) admits a factorisation \( X_R Y_R Z_R \) for some non-empty word \( Y_R \). If moreover the presentation satisfies the stronger condition \( C(4) \) then \( R \) cannot be written as a product of three pieces, so \( Y_R \) is not a piece. The converse also holds: a \( C(3) \) presentation such that no \( Y_R \) is a piece is a \( C(4) \) presentation. We call \( X_R, Y_R \) and \( Z_R \) the maximal piece prefix, the middle word and the maximal piece suffix respectively of \( R \).

Assuming now that the presentation satisfies at least the condition \( C(3) \), we shall use the letters \( X, Y \) and \( Z \) (sometimes with adornments or subscripts) exclusively to represent maximal piece prefixes, middle words and maximal piece suffixes respectively of relation words; two such letters with
the same subscript or adornment (or with none) will be assumed to stand
for the appropriate factors of the same relation word.

If \( R \) is a relation word we write \( \overline{R} \) for the (necessarily unique, as a result of
the small overlap condition) word such that \((R, \overline{R})\) or \((\overline{R}, R)\) is a relation in
the presentation. We write \( X_R, Y_R \) and \( Z_R \) respectively.
(This is an abuse of notation since, for example, the word \( X_R \) may be a
maximal piece prefix of two distinct relation words, but we shall be careful
to ensure that the meaning is clear from the context.)

2. Weak Cancellation Properties

To perform efficient computations with words, it is very helpful to be
able to process them in a sequential, left-right manner. To facilitate this
in the case of the word problem for small overlap monoids, we need to
know what can be deduced about the equivalence (or non-equivalence) of
two words from prefixes of those words. This section develops a theory
with this end in mind, including a number of results which can be viewed
as weak cancellativity conditions satisfied by small overlap monoids. We
assume throughout a fixed monoid presentation satisfying the small overlap
condition \( C(4) \).

We first introduce some terminology. A relation prefix of a word is a prefix
which admits a (necessarily unique, as a consequence of the small overlap
condition) factorisation of the form \( aXY \) where \( X \) and \( Y \) are the maximal
piece prefix and middle word respectively of some relation word \( XYZ \). An
overlap prefix (of length \( n \)) of a word \( u \) is a relation prefix which admits
an (again necessarily unique) factorisation of the form \( bX_1Y'_1X_2Y'_2\ldots X_nY_n \)
where

- \( n \geq 1 \);
- no factor of the form \( X_0Y_0 \) begins before the end of the prefix \( a \);
- for each \( 1 \leq i \leq n \), \( R_i = X_iY_iZ_i \) is a relation word with \( X_i \) and \( Z_i \)
  the maximal piece prefix and suffix respectively; and
- for each \( 1 \leq i < n \), \( Y'_i \) is a proper, non-empty prefix of \( Y_i \).

Notice that if a word has a relation prefix, then the shortest such must be
an overlap prefix. A relation prefix \( aXY \) of a word \( u \) is called clean if \( u \) does not have a prefix

\[ aXY'X_1Y_1 \]

where \( X_1 \) and \( Y_1 \) are the maximal piece prefix and middle word respectively
of some relation word, and \( Y' \) is a proper, non-empty prefix of \( Y \). Clean
overlap prefixes, in particular, will play a crucial role in what follows.

**Proposition 1.** Let \( aX_1Y'_1X_2Y'_2\ldots X_nY_n \) be an overlap prefix of some word.
Then this prefix contains no relation word as a factor (except possibly \( X_nY_n \)
in the case that \( Z_n = \epsilon \)).

**Proof.** Suppose that the given overlap prefix contains a relation word \( R \) as
a factor. By the definition of an overlap prefix, no occurrence of \( R \) can
begin before the end of the prefix \( a \), so we may assume that \( R \) is a factor of
\( X_1Y'_1X_2Y'_2\ldots X_nY_n \). It follows that either \( R \) contains \( X_iY'_i \) as a factor for
some \( i \), or else \( R \) is a factor of \( X_iY'_iX_{i+1}Y'_{i+1} \) for some \( i \) (where \( Y'_{i+1} = Y_n \) if
and we may assume without loss of generality that the occurrence of \( R \) overlaps non-trivially with the prefix \( X_iY_i' \).

In the former case, since \( X_i \) is a maximal piece prefix of \( X_iY_iZ_i \) and \( Y_i' \) is non-empty, \( X_iY_i' \) cannot be a piece; it follows then that we must have \( R = X_iY_iZ_i \) with the occurrence in the obvious place. In the latter case, \( R \) is the product of a non-empty factor of \( X_iY_{i+1}Z_{i+1} \); but by the small overlap assumption, \( R \) cannot be written as a product of two pieces, so it must again be that \( R = X_iY_iZ_i \) with the occurrence in the obvious place.

Now if \( i = n \) then, since \( R \) is a factor of the given relation prefix, we must clearly have \( R = X_iY_iZ_i = X_iY_i \) so that \( Z_i = \epsilon \). On the other hand, if \( i < n \) then either \( X_iY_iZ_i \) contains \( X_{i+1}Y_{i+1}'Z_{i+1} \) as a factor, which contradicts the fact that \( X_{i+1} \) is a maximal piece prefix of \( X_iY_iZ_i \), or else (recalling that \( Y_i' \) is a proper prefix of \( Y_i \)) we see that \( X_{i+1}Y_{i+1}' \) contains a non-empty suffix of \( Y_i \) followed by \( Z_i \), which contradicts the fact that \( Z_i \) is a maximal piece suffix of \( X_iY_iZ_i \).

\[ \square \]

**Proposition 2.** Let \( u \) be a word. Every overlap prefix of \( u \) is contained in a clean overlap prefix of \( u \).

**Proof.** We fix \( u \) and prove by induction on the difference between the length of \( u \) and the length of the given overlap prefix, that is, on the length of that part of \( u \) not contained in the given overlap prefix. For the base case, observe that an overlap prefix constituting the whole of \( u \) is necessarily clean. Now suppose \( aX_1Y_1' \ldots X_nY_n \) is an overlap prefix, and that the result holds for longer overlap prefixes of \( u \). If the given prefix is clean then there is nothing to prove. Otherwise, by the definition of a clean overlap prefix, there exist words \( X \) and \( Y \), being the maximal piece prefix and the middle word respectively of some relation word, and a proper non-empty prefix \( Y_{i}' \) of \( Y_n \) such that

\[ aX_1Y_1' \ldots X_nY_i'XY \]

is a prefix of \( u \). Clearly this is an overlap prefix of \( u \) which is strictly longer than the original one, and so by induction is contained in a clean overlap prefix of \( u \). But now the original overlap prefix of is contained in a clean overlap prefix, as required.

\[ \square \]

**Corollary 1.** If a word \( u \) has no clean overlap prefix, then it contains no relation word as a factor, and so if \( u \equiv v \) then \( u = v \).

**Proof.** Suppose \( u \) has no clean overlap prefix. If \( u \) contained a relation word as a factor then clearly it would have a relation prefix, that is, a prefix of the form \( aX_1R \) for some relation word \( R \). But by our observations above, the shortest relation prefix of \( u \) would be an overlap prefix, and so by Proposition 2 is contained in a clean overlap prefix of \( u \). Thus, \( u \) contains no relation word as a factor. It follows easily that no relations can be applied to \( u \), so the only word equivalent to \( u \) is \( u \) itself.

\[ \square \]

**Lemma 1.** If \( u = wXYZu' \) with \( wXY \) a clean overlap prefix then \( wXY \) is a clean overlap prefix of \( wXYZu' \).

**Proof.** Let

\[ wXY = aX_1Y_1' \ldots X_nY_n'XY \] (1)
be the factorisation given by the definition of a clean overlap prefix. Then \( wXYZu' \) has a prefix
\[
wXYZ = aX_1Y'_1 \cdots X_nY'_nXY
\]
(2)

If \( n \geq 1 \) it is immediate from the factorisation given by (2) that \( wXYZ \) is an overlap prefix of \( wXYZu' \). In the case \( n = 0 \), however, we must consider the possibility that the prefix \( aXY \) contains a factor of the form \( X_0Y_0 \) overlapping the final initial segment \( a \). Suppose it does. Then recalling that \( Y_0 \) is not a piece, and so cannot be a factor of \( XY \), we see that \( aXY \) admits a factorisation
\[
aXY = bX_0Y_0XY
\]
(3)
for some non-empty prefix \( Y_0' \) or \( Y_0 \). Moreover, \( Y_0' \) must be a proper prefix of \( Y_0 \), or else \( a \) would have a factor \( X_0Y_0 \), contradicting the fact that \( wXY \) was a clean overlap prefix of \( u \). This shows that \( wXY \) is an overlap prefix of \( wXYZu' \).

It remains to show that the given overlap prefix is clean. Suppose for a contradiction that it is not. Then by definition, there is a factor of the form \( \hat{X}\hat{Y} \) overlapping the end of the prefix \( aXY \); but this factor is either by contained in \( XYZ \) (contradicting the supposition that \( \hat{X} \) is a maximal piece prefix of a relation word \( \hat{X}\hat{Y}\hat{Z} \)) or contains a non-empty suffix of \( Y \) followed by \( Z \) (contradicting the assumption that \( Z \) is a maximal piece suffix of \( XYZ \)). □

The following lemma is fundamental to our approach to \( C(4) \) monoids. With careful application it seems to permit a comparable understanding to that resulting from Remmers’ geometric theory, but in a purely combinatorial (and hence more computationally orientated) way.

**Lemma 2.** Suppose a word \( u \) has clean overlap prefix \( wXY \). If \( u \equiv v \) then \( v \) has overlap prefix either \( wXY \) or \( wXY' \), and no relation word occurring as a factor of \( v \) overlaps this prefix, unless it is \( XYZ \) or \( XYZ \) as appropriate.

**Proof.** Since \( wXY \) is an overlap prefix of \( u \), it has by definition a factorisation
\[
wXY = aX_1Y'_1 \cdots X_nY'_nXY
\]
for some \( n \geq 0 \). We use this fact to prove the claim by induction on the length \( r \) of a rewrite sequence (using the defining relations) from \( u \) to \( v \).

In the case \( r = 0 \), we have \( u = v \), so \( v \) certainly has (clean) overlap prefix \( vXY \). By Proposition \( \exists \) no relation word factor can occur entirely within this prefix (unless it is \( XY \) and \( Z = \epsilon \)). If a relation word factor of \( v \) overlaps the end of the given overlap prefix and entirely contains \( XY \) then, since \( XY \) is not a piece, that relation word must clearly be \( XYZ \). Finally, a relation word cannot overlap the end of the given overlap prefix but not contain the suffix \( XY \), since this would clearly contradicts the fact that the given overlap prefix is clean.

Suppose now for induction that the lemma holds for all values less than \( r \), and that there is a rewrite sequence from \( u \) to \( v \) of length \( r \). Let \( u_1 \) be the second term in the sequence, so that \( u_1 \) is obtained from \( u \) by a single rewrite using the defining relations, and \( v \) from \( u_1 \) by \( r - 1 \) rewrites.
Consider the relation word in $u$ which is to be rewritten in order to obtain $u_1$, and in particular its position in $u$. By Proposition 1, this relation word cannot be contained in the clean overlap prefix $wXY$, unless it is $XY$ where $Z = \epsilon$.

Suppose first that the relation word to be rewritten contains the final factor $Y$ of the given clean overlap prefix. (Note that this covers in particular the case that the relation word is $XY$ and $Z = \epsilon$.) From the $C(4)$ assumption we know that $Y$ is not a piece, so we may deduce that the relation word is $XYZ$ contained in the obvious place. In this case, applying the rewrite clearly leaves $u_1$ with a prefix $wXY$, and by Lemma 1 this is a clean overlap prefix. Now $v$ can be obtained from $u_1$ by $r-1$ rewrite steps, so it follows from the inductive hypothesis that $v$ has overlap prefix either $wXY$ or $wXY = wXY$, and that no relation word occurring as a factor of $v$ overlaps this prefix, unless it is $XYZ$ or $XYZ$ as appropriate; this completes the proof in this case.

Next, we consider the case in which the relation word factor in $u$ to be rewritten does not contain the final factor $Y_n$ of the clean overlap prefix, but does overlap with the end of the clean overlap prefix. Then $u$ has a factor of the form $XY$, where $X$ is the maximal piece prefix and $Y$ the middle word of a relation word, which overlaps $X_nY_n$, beginning after the start of $Y_n$. This clearly contradicts the assumption that the overlap prefix is clean.

Finally, we consider the case in which the relation word factor in $u$ which is to be rewritten does not overlap the given clean overlap prefix at all. Then obviously, the given clean overlap prefix of $u$ remains an overlap prefix of $u_1$. If this overlap prefix is clean, then a simple application of the inductive hypothesis again suffices to prove that $v$ has the required property.

There remains, then, only the case in which the given overlap prefix is no longer clean in $u_1$. Then by definition there exist words $X$ and $Y$, being a maximal piece prefix and middle word respectively of some relation word, such that $u_1$ has the prefix

\[ aX_1Y_1' \ldots X_{n-1}Y_{n-1}'X_nY_n'XY \]

for some proper, non-empty prefix $Y_n'$ of $Y_n$. Now certainly this is not a prefix of $u$, since this would contradict the assumption that $aX_1Y_1' \ldots X_nY_n$ is a clean overlap prefix of $u$. So we deduce that $u_1$ must contain a relation word overlapping the final $XY$. This relation word cannot contain the final factor $XY$, since this would again contradict the assumption that $aX_1Y_1' \ldots X_nY_n$ is a clean overlap prefix of $u$. Nor can the relation word contain the final factor $Y$, since $Y$ is not a piece. Hence, $u_1$ must have a prefix

\[ aX_1Y_1' \ldots X_{n-1}Y_{n-1}'X_nY_n'XY'R \]

for some relation word and proper, non-empty prefix $Y'$ of $Y$ and some relation word $R$. Suppose $R = X_RY_RZ_R$ where $X_R$ and $Z_R$ are the maximal piece prefix and suffix respectively. Then it is readily verified that

\[ aX_1Y_1' \ldots X_{n-1}Y_{n-1}'X_nY_n'XY'RX_RY_R \]

is a clean overlap prefix of $u_1$. But now by the inductive hypothesis, $v$ has prefix either

\[ aX_1Y_1' \ldots X_{n-1}Y_{n-1}'X_nY_n'XY'X_RY_R \]

(4)
or
\[ aX_1Y'_1 \cdots X_{n-1}Y'_{n-1}X_nY'_{n-1}XY'R \]  \hspace{1cm} (5)

and so in particular it certainly has prefix
\[ aX_1Y'_1 \cdots X_{n-1}Y'_{n-1}X_nY'_{n-1}X Y' \]
which in turn is easily seen to have prefix
\[ aX_1Y'_1 \cdots X_{n-1}Y'_{n-1}X_nY' \]  \hspace{1cm} (6)

Moreover, by Proposition 1, the prefix (4) or (5) of \( v \) contains no relation word as a factor (unless it is the final factor \( X_R Y_R \) and \( Z_R = \epsilon \)) and it follows easily that no relation word factor overlaps the prefix (6) of \( v \). \[ \square \]

The lemma has the following easy corollary.

**Corollary 2.** Suppose a word \( u \) has (not necessarily clean) overlap prefix \( wXY \). If \( u \equiv v \) then \( v \) has a prefix \( w \) and contains no relation word overlapping this prefix.

**Proof.** By Proposition 2 the overlap prefix \( wXY \) of \( u \) is contained in a clean overlap prefix \( w'X'Y' \) of \( u \). Now by Lemma 2, \( v \) has a prefix \( w' \) and contains no relation word overlapping this prefix. But it is easily seen that \( w' \) must be at least as long as \( w \), so that \( v \) has a prefix \( w \) and contains no relation word overlapping this prefix, as required. \[ \square \]

The following proposition describes a very weak left cancellation property of small overlap monoids; it will allow us to restrict attention to words with a prefix of the form \( XY \) where \( X \) and \( Y \) are the maximal piece prefix and middle word respectively of some relation word.

**Proposition 3.** Suppose a word \( u \) has an overlap prefix \( aXY \) and that \( u = aXYu'' \). Then \( u \equiv v \) if and only if \( v = av' \) where \( v' \equiv XYu'' \).

**Proof.** Clearly if \( v = av' \) with \( v' \equiv X_1Y_1u'' \) then it is immediate that \( v = av' \equiv aX_1Y_1u'' = v \).

Conversely, suppose \( u \equiv v \). Since \( aXY \) is an overlap prefix, by Proposition 1 it cannot contain a relation word starting before the end of \( a \). By Corollary 2 \( v \) has prefix \( a \), say \( v = av' \). Now consider a rewrite sequence, using the defining relations, from \( u \) to \( v \). Again using Corollary 2 every term in this sequence will have prefix \( a \), and contain no relation word overlapping this prefix. It follows that the same sequence of rewrites can be applied to take \( X_1Y_1u'' \) to \( v' \), so that \( v' \equiv X_1Y_1u'' \) as required. \[ \square \]

We now introduce some more terminology. Let \( u \) be a word with shortest relation prefix \( aXY \), and let \( p \) be a piece. We say that \( u \) is \( p \)-inactive if \( pu \) has shortest relation prefix \( paXY \) and \( p \)-active otherwise. The following proposition describes another weak cancellation property of small overlap monoids.

**Proposition 4.** Let \( u \) be a word and \( p \) a piece. If \( u \) is \( p \)-inactive then \( pu \equiv v \) if and only if \( v = pw \) for some \( w \) with \( u \equiv w \).
Proof. Suppose $u$ has shortest relation prefix $aXY$, so that $pu$ has shortest relation prefix $paXY$. Suppose $u = aXYu''$. If $pu v$ then by Proposition 3 (since the shortest relation prefix is clearly an overlap prefix), we have $v = pav'$ where $v' = XYu'$. Now setting $w = av'$ we have $v = pw$ and $u = aXYu' = av' = aw$. The converse implication is obvious.

Proposition 5. Let $Z_1$ and $Z_2$ be maximal piece suffixes of relation words and suppose $u$ is $Z_1$-active and $Z_2$-active. Then $Z_1$ and $Z_2$ have a common non-empty suffix, and if $z$ is the maximal common suffix then

(i) $u$ is $z$-active;
(ii) $Z_1u = v$ if and only if $v = z_1v'$ where $z_1z = Z_1$ and $v' = zu$; and
(iii) $Z_2u = v$ if and only if $v = z_2v'$ where $z_2z = Z_2$ and $v' = zu$.

Proof. Let $bX_3Y_3$ and $cX_4Y_4$ be the shortest relation prefixes of $Z_1u$ and $Z_2v$ respectively. Since $u$ is $Z_1$-active and $Z_2$-active, we must have $|b| < |Z_1|$ and $|c| < |Z_2|$. Moreover, since $Z_1$ is a piece and $X_3$ is a maximal piece prefix of the relation word $X_3Y_3Z_3$ we must have $|Z_1| = |bX_3|$, and similarly $|Z_2| = |cX_4|$.

It follows that $u$ has prefixes $X_3'Y_3$ and $X_4'Y_4$ where $X_3'$ and $X_4'$ are proper (perhaps empty) suffixes of $X_3$ and $X_4$ respectively. Thus, one of $X_3'Y_3$ and $X_4'Y_4$ is a prefix of the other, and so either $Y_3$ is a factor of $X_4'Y_4$ and hence of $X_4'Y_4Z_4$ or $Y_4$ is a factor of $X_3'Y_3$ and hence of $X_3'Y_3Z_3$. But by the $C(4)$ assumption, neither $Y_3$ nor $Y_4$ is a piece so the only possible explanation is that $X_3Y_3Z_3$ and $X_4Y_4Z_4$ are the same relation word, and moreover $X_3' = X_4'$.

Now let $p$ be such that $pX_3' = X_3$. We have already observed that $X_3'$ is a proper prefix of $X_3$, so $p$ is non-empty. Now $Z_1 = bp$, and also

$$pX_4' = pX_3' = X_3 = X_4$$

so by symmetry we have $Z_2 = cp$. Hence, $p$ is a common non-empty suffix of $Z_1$ and $Z_2$.

Now let $z$ be the maximal common suffix of $Z_1$ and $Z_2$. Let $y$, $z_1$ and $z_2$ be such that $z = yp$, $Z_1 = z_1z$ and $Z_2 = z_2z$. Then clearly $b = z_1y$ and $c = z_2y$. Now $zu = ypu$ has a relation prefix $yX_3Z_3$, from which it is immediate that $u$ is $z$-active so that (i) holds.

To show that (ii) holds, let $u'$ be such that $u = X_3'Y_3u'$, and suppose $u \equiv v$. Now

$$Z_1u = z_1zX_3'Y_3u' = z_1ypX_3'Y_3u' = z_1yX_3'Y_3u'$$

where $z_1yX_3Z_3$ is the shortest relation prefix, and hence is an overlap prefix. Hence, by Proposition 3 we have $v = z_1yv''$ where $v'' \equiv X_3Y_3u'$. But now setting $v' = yv''$ we have $v = z_1v'$, $z_1z = Z_1$ and

$$v' = yv'' \equiv yX_3Y_3u' = ypX_3'Y_3u' = zX_3'Y_3u' = zu$$

as required. Conversely, if $v = z_1v'$ where $z_1z = Z_1$ and $v' \equiv zu$ then we have

$$Z_1u = z_1zu \equiv z_1v' = v.$$ 

This completes the proof that (ii) holds, and an entirely symmetric argument shows that (iii) holds. □
**Corollary 3.** Let $Z_1$ and $Z_2$ be maximal piece suffixes of relation words. Suppose $u$ is $Z_2$-active and $Z_1 u ≡ Z_1 v$. Then $Z_2 u ≡ Z_2 v$.

*Proof.* If $u$ is $Z_1$-inactive then by Proposition 1 we have $u ≡ v$, and so certainly $Z_2 u ≡ Z_2 v$.

On the other hand, if $u$ is $Z_1$-active then let $z$ be the maximal common suffix of $Z_1$ and $Z_2$ and let $z_1$ and $z_2$ be such that $z_1 z = Z_1$ and $z_2 z = Z_2$. Then by the Proposition 5(ii), since $Z_1 u ≡ Z_1 v$ we have $Z_1 v = z_1 v'$ where $v' ≡ z u$. But from $z_1 z v = Z_1 v = z_1 v'$ we deduce that $v' = z v$, so now we have

$$Z_2 u = z_2 z u ≡ z_2 z v' = z_2 z v = Z_2 v.$$ 

□

**Corollary 4.** Let $u$ and $v$ be words and $Z_1$ and $Z_2$ be maximal piece suffixes of relation words. Suppose there exist words $u = u_1, \ldots, u_n = v$ such that

$$Z_1 u_1 ≡ Z_1 u_2, \ Z_2 u_2 ≡ Z_2 u_3, \ Z_1 u_3 ≡ Z_1 u_4, \ldots$$

$$\ldots, \begin{cases} Z_1 u_{n-1} ≡ Z_1 u_n & \text{if } n \text{ is even} \\ Z_2 u_{n-1} ≡ Z_2 u_n & \text{if } n \text{ is odd.} \end{cases}$$

Then either $Z_1 u ≡ Z_1 v$ or $Z_1 u ≡ Z_2 v$ or both.

*Proof.* Fix $u$ and $v$, and suppose $n$ is minimal (allowing exchanging $Z_1$ and $Z_2$ if necessary) such that a sequence of equivalences as above exists. Suppose further for a contradiction that $n > 2$. If $u_2$ was $Z_1$-inactive then by Proposition 1 we would have $u_1 ≡ u_2$ so that $Z_2 u_1 ≡ Z_2 u_2 ≡ Z_2 u_3$, contradicting the minimality assumption on $n$. Similarly, if $u_2$ was $Z_2$-inactive then we would have $u_2 ≡ u_3$ so that $Z_1 u_1 ≡ Z_1 u_2 ≡ Z_1 u_3$ again contradicting the minimality assumption on $n$.

Thus, $u_2$ is both $Z_1$-active and $Z_2$-active. But now since $Z_1 u_1 ≡ Z_1 u_2$, we apply Corollary 3 to see that $Z_2 u_1 ≡ Z_2 u_2 ≡ Z_2 u_3$, again providing the required contradiction. □

3. Sequential Characterisation of Equality

In this section we use the theory developed in Section 2 to provide a new characterisation of when two words in the generators of a small overlap presentation represent the same element of the monoid presented. In Section 4 we shall use this characterisation to develop an efficient algorithm to solve the word problem.

We first present a lemma which gives a set of mutually exclusive combinatorial conditions, the disjunction of which is necessary and sufficient for two words of a certain form to represent the same element.

**Lemma 3.** Suppose $u = XY u'$ where $XY$ is a clean overlap prefix of $u$. Then $u ≡ v$ if and only if one of the following mutually exclusive conditions holds:

1. $u = XYZ u''$ and $v = XYZ v''$ and either $Z u'' ≡ Z v''$ or $\overline{Z} u'' ≡ \overline{Z} v''$ or both;
2. $u = XY u'$, $v = XY v'$, and $Z$ fails to be a prefix of at least one of $u'$ and $v'$, and $u' ≡ v'$;
(3) \( u = X Y Z u'' \), \( v = X Y Z v'' \) and either \( Zu'' \equiv Zv'' \) or \( Z u'' \equiv Z v'' \) or both;

(4) \( u = X Y u' \), \( v = X Y Z v'' \) but \( Z \) is not a prefix of \( u' \) and \( u' \equiv Z v'' \);

(5) \( u = X Y Z u'' \), \( v = X Y v' \) but \( Z \) is not a prefix of \( v' \) and \( Z u'' \equiv v' \);

(6) \( u = X Y u' \), \( v = X Y v' \), \( Z \) is not a prefix of \( u' \) and \( Z \) is not a prefix of \( v' \), but \( Z = z_1 z \), \( \overline{Z} = z_2 z \), \( u' = z_1 u'' \), \( v' = z_2 v'' \) where \( u'' \equiv v'' \) and \( z \) is the maximal common suffix of \( Z \) and \( \overline{Z} \), \( z \) is non-empty, and \( z \) is a possible prefix of \( u'' \).

**Proof.** First we treat the claim that the conditions (1)-(6) are mutually exclusive. Since \( X \) is a maximal piece prefix of \( X Y Z \) and \( Y \) is non-empty, \( X Y \) is not a piece. An entirely similar argument shows that \( X Y \) is not a piece. In particular, neither of \( X Y \) and \( \overline{X Y} \) is a prefix of the other, and so \( v \) can have at most one of them as a prefix. Thus, conditions (1)-(2) are not consistent with conditions (3)-(6). The mutual exclusivity of (1) and (2) is self-evident from the definitions, and likewise that of (3)-(6).

It is easily verified that each of the conditions (1)-(5) imply that \( u \equiv v \). We show next that (6) implies that \( u \equiv v \). Since \( z \) is a possible prefix of \( u'' \) and \( u'' \equiv v'' \), we may write \( u'' \equiv x z \equiv v'' \) for some word \( x \). Now we have

\[
\begin{align*}
    u &= X Y u' = X Y z_1 u'' = X Y z_1 z x = X Y Z x \\
    &= X Y Z x = X Y z_1 z x = X Y z_2 u'' = X Y z' = v.
\end{align*}
\]

What remains, which is the main burden of the proof, is to prove that \( u \equiv v \) implies that at least one of the conditions (1)-(6) holds. To this end, then, suppose \( u \equiv v \); then there is a rewriting sequence taking \( u \) to \( v \). By Lemma 2, every term in this sequence will have prefix either \( X Y \) or \( \overline{X Y} \) and this prefix can only be modified by the application of the relation \( (X Y Z, \overline{X Y Z}) \) in the obvious place. We now prove the claim by case analysis.

By Lemma 2, \( v \) begins either with \( X Y' \) or with \( \overline{X Y} \). Consider first the case in which \( v \) begins with \( X Y \); we split this into two further cases depending on whether \( u \) and \( v \) both begin with the full relation word \( X Y Z \); these will correspond respectively to conditions (1) and (2) in the statement of the lemma.

**Case (1).** Suppose \( u = X Y Z u'' \) and \( v = X Y Z v'' \). Then clearly there is a rewriting sequence taking \( u \) to \( v \) which by Lemma 2 can be broken up as:

\[
\begin{align*}
    u &= X Y Z u'' \rightarrow X Y Z u_1 \rightarrow X Y Z u_1 \rightarrow X Y Z u_2 \\
    &= X Y Z u_2 \rightarrow \cdots \rightarrow X Y Z u_n \rightarrow X Y Z v'' = v
\end{align*}
\]

where none of the steps in the sequences indicated by \( \rightarrow \) involves rewriting a relation word overlapping with the prefix \( X Y \) or \( \overline{X Y} \) as appropriate. It follows that there are rewriting sequences.

\[
Z u'' \rightarrow Z u_1, \overline{Z} u_1 \rightarrow \overline{Z} u_2, Z u_2 \rightarrow \overline{Z} u_3, \ldots, Z u_n \rightarrow \overline{Z} v''
\]

Now by Corollary 3 either \( Z u'' \equiv Z v'' \) or \( \overline{Z} u'' \equiv \overline{Z} v'' \) as required to show that condition (1) holds.

**Case (2).** Suppose now that \( u = X Y u' \), \( v = X Y v' \) and \( Z \) fails to be a prefix of at least one of \( u' \) and \( v' \). We must show that \( u' \equiv v' \); suppose for a contradiction that this does not hold. We consider only the case that \( Z \) is not a prefix of \( u' \); the case that \( Z \) is not a prefix of \( v' \) is symmetric.
We consider rewriting sequences from \( u = XYu' \) to \( v = XYv' \). Again using Lemma 2, we see that there is either (i) such a sequence taking \( u \) to \( v \) containing no rewrites of relation words overlapping the prefix \( XY \), or (ii) such a sequence taking \( u \) to \( v \) which can be broken up as:

\[
\begin{align*}
u &= XYu' \rightarrow^{*} XYZu_1 \rightarrow \overline{XYZ}u_1 \rightarrow^{*} \overline{XYZ}u_2 \\
&\rightarrow XYZu_2 \rightarrow^{*} \cdots \rightarrow XYZu_n \rightarrow^{*} XYv' = v
\end{align*}
\]

where none of the intermediate words in the sequences indicated by \( \rightarrow^{*} \) contain a relation word overlapping with the prefix \( XY \) or \( \overline{XY} \) as appropriate. In case (i) there is clearly a rewrite sequence taking \( u \) to \( v' \) so that \( u' \equiv v' \) as required. In case (ii), there are rewriting sequences.

\[
u' \rightarrow^{*} Zu_1, Zu_1 \rightarrow^{*} Zu_2, Zu_2 \rightarrow^{*} Zu_3, \ldots, Zu_n \rightarrow^{*} v'.
\]

Notice that, since \( u' \) does not begin with \( Z \), we can deduce from Proposition 1 that \( u_1 \) is \( Z \)-active. By Corollary 1 either \( Zu_1 \equiv Zu_n \) or \( \overline{Z}u_1 \equiv \overline{Z}u_n \). In the latter case, since \( u_1 \) is \( Z \)-active, Corollary 2 tells us that we also have \( Zu_1 \equiv Zu_n \) in any case. But now

\[
u' \equiv Zu_1 \equiv Zu_n \equiv v'
\]

so condition (2) holds and we are done.

We have now shown that if \( v \) begins with \( XY \) then either condition (1) or condition (2) holds. It remains to consider the case in which \( v \) begins with \( \overline{XY} \), and show that one of conditions (1)-(6) must be satisfied. We split the analysis here into four cases depending on whether \( u \) begins with the full relation word \( XYZ \); these four cases will correspond respectively to conditions (3)-(6) in the statement of the lemma.

**Case (3).** Suppose \( u = XYZu'' \) and \( v = \overline{XY}v'' \). Then \( u = XYZu'' \equiv v \equiv XYZv'' \), so by the same argument as in case (1) we have either \( Zu'' \equiv Zv'' \) or \( \overline{Z}u'' \equiv \overline{Z}v'' \) as required to show that condition (3) holds.

**Case (4).** Suppose \( u = XYu' \) and \( v = \overline{XY}v'' \) but \( Z \) is not a prefix of \( u' \). Then \( u = XYu' \equiv v \equiv XYZv'' \). Now applying the same argument as in case (2) (with \( XYZv'' \) in place of \( v \) and setting \( v' = Zv'' \)) we have \( u' \equiv v' = Zv'' \) so that condition (4) holds.

**Case (5).** Suppose \( u = XYZu'', v = \overline{XY}v' \) but \( Z \) is not a prefix of \( v' \). Then we have \( XYZu'' \equiv u \equiv v \equiv \overline{XY}v' \). Now applying the same argument as in case (1) (but with \( XYZv'' \) in place of \( u \) and setting \( u' = Zu'' \)) we obtain \( u' \equiv v' = \overline{Z}u'' \) so that condition (5) holds.

**Case (6).** Suppose \( u = XYu' \), \( v = \overline{XY}v' \) and that \( Z \) is not a prefix of \( u' \) and \( Z \) is not a prefix of \( v' \). It follows this time there is a rewriting sequence taking \( u \) to \( v \) of the form

\[
\begin{align*}
u &= XYu' \rightarrow^{*} XYZu_1 \rightarrow \overline{XYZ}u_1 \rightarrow^{*} \overline{XYZ}u_2 \rightarrow XYZu_2 \\
&\rightarrow^{*} \cdots \rightarrow \overline{XYZ}u_n \rightarrow^{*} \overline{XY}v' = v
\end{align*}
\]

where once more none of the intermediate words in the sequences indicated by \( \rightarrow^{*} \) contain a relation word overlapping with the prefix \( XY \) or \( \overline{XY} \) as appropriate. Now there are rewriting sequences.

\[
u' \rightarrow^{*} Zu_1, Zu_1 \rightarrow^{*} Zu_2, Zu_2 \rightarrow^{*} Zu_3, \ldots, Zu_{n-1} \rightarrow^{*} Zu_n, Zu_n \rightarrow^{*} v'.
\]
Notice that, since $u'$ does not begin with $Z$, we may deduce from Proposition 4 that $u_1$ is $Z$-active. By Corollary 4, either $Zu_1 \equiv Zu_n$ or $Zu_1 \equiv \overline{Z}u_n$. In the latter case, since $u_1$ is $Z$-active, Corollary 3 tells us that we also have $Zu_1 \equiv Zu_n$ anyway. But now
\[ u' \equiv Zu_1 \equiv Zu_n \]
where $u'$ does not begin with $Z$, and also $v' \equiv \overline{Z}u_n$ were $v'$ does not begin with $Z$. By applying Proposition 4 twice, we deduce that $u_n$ is both $Z$-active and $Z$-active.

Let $z$ be the maximal common suffix of $Z$ and $\overline{Z}$. Then applying Proposition 5 (with $Z_1 = Z$ and $Z_2 = \overline{Z}$), we see that $z$ is non-empty and
\begin{itemize}
  \item $u' = z_1u''$ where $Z = z_1z$ and $u'' \equiv zu_n$; and
  \item $v' = z_2v''$ where $\overline{Z} = z_2z$ and $v'' \equiv zu_n$.
\end{itemize}
But then we have $u'' \equiv zu_n \equiv v''$ and also $z$ is a possible prefix of $u''$ as required to show that condition (6) holds.

Lemma 3 gives a first clue as to how one might solve the word problem for a small overlap monoid by analysing words sequentially from left to right. The natural strategy is as follows. First, use Proposition 3 to reduce to the case in which the words both have clean relation prefixes of the form $XY$ or $\overline{XY}$. Now by examining short prefixes, one can clearly always rule out at least five of the six mutually exclusive conditions of the lemma. The remaining condition will involve equivalence of words derived from suffixes of $u$ and $v$, so apply the same approach recursively to test whether this condition is satisfied.

This approach meets with several apparent obstacles. Firstly, it is not clear that the words derived from the suffixes of $u$ and $v$, which must be tested for equivalence in the recursive call, are shorter than the original words $u$ and $v$; for example, a relation word $XYZ$ may be shorter than the maximal piece suffix $Z$ of the word on the other side of the relation. In fact the recursive call will not always involve shorter words, but it will involve words which are simpler in a more subtle sense, so that the algorithm still terminates rapidly. Secondly, some of the conditions involve a disjunction of equivalence of two pairs of words derived from the suffixes; testing both would require two recursive calls, potentially leading to exponential time complexity. It transpires, though, that the theory of activity and inactivity developed in Section 2 means that one recursive call will always suffice. Finally, some of the conditions require us to check the possible prefixes of words derived from suffixes; this problem is solved by the following development of Lemma 3, which gives simultaneous conditions for two words to be equal, and to admit a given piece as a possible prefix.

**Lemma 4.** Suppose $u = XYu'$ where $XY$ is a clean overlap prefix, and suppose $p$ is a piece. Then $u \equiv v$ and $p$ is a possible prefix of $u$ if and only if one of the following mutually exclusive conditions holds:

\begin{enumerate}
  \item[(1')] $u = XYZu''$ and $v = XYZv''$, either $Zu'' \equiv Zv''$ or $\overline{Z}u'' \equiv \overline{Z}v''$, and also $p$ is a prefix of either $X$ or $\overline{X}$ or both;
  \item[(2')] $u = XYu'$, $v = XYv'$, and $Z$ fails to be a prefix of at least one of $u'$ and $v'$, and $u' \equiv v'$, and also either
\end{enumerate}
– $p$ is a prefix of $X$
– $p$ is a prefix of $\overline{X}$ and $Z$ is a possible prefix of $u'$; or both;

(3') $u = XYZu''$, $v = \overline{XY}Zu''$ and either $Zu'' \equiv Zu''$ or $\overline{Zu''} \equiv \overline{Zv''}$ or both,
and also $p$ is a prefix of $X$ or $\overline{X}$ or both;

(4') $u = XYu'$, $v = \overline{XY}Zu''$ but $Z$ is not a prefix of $u'$ and $u' \equiv Zv''$,
and also $p$ is a prefix of $X$ or $\overline{X}$ or both;

(5') $u = XYZu''$, $v = \overline{XY}v'$ but $\overline{Z}$ is not a prefix of $v'$ and $\overline{Zu''} \equiv v'$,
and also $p$ is a prefix of $X$ or $\overline{X}$ or both;

(6') $u = XYu'$, $v = \overline{XY}v'$, $Z$ is not a prefix of $u'$ and $\overline{Z}$ is not a prefix
of $v'$, but $Z = z_1z$, $\overline{Z} = z_2\overline{z}$, $u' = z_1u''$, $v' = z_2v''$ where $u'' \equiv v''$, $z$
is the maximal common suffix of $Z$ and $\overline{Z}$, $z$ in non-empty, $z$ is a possible
prefix of $u''$, and also $p$ is a prefix of $X$ or $\overline{X}$ or both.

Proof. Mutual exclusivity of the six conditions is proved exactly as for Lemma 3.

Suppose now that one of the six conditions above applies. Each condition clearly implies the corresponding condition from Lemma 3 so we deduce immediately that $u \equiv v$. We must show, using the fact that $p$ is a prefix of $X$ or of $\overline{X}$, that $p$ is a possible prefix of $u$, or equivalently of $v$.

In case (1'), if $p$ is a prefix of $X$ then it is a prefix of $u$, while if $p$ is a prefix of $\overline{X}$ then it is a prefix of $\overline{XY}Zu''$ which is clearly equivalent to $u$. In case (2'), if $p$ is a prefix of $X$ then it is again a prefix of $u$, while if $p$ is a prefix of $\overline{X}$ and $Z$ is a possible prefix of $u'$, say $u' \equiv Zw$, then

$$u = XYu' \equiv XYZw \equiv \overline{XY}Zw$$

where the latter has $p$ as a prefix. In the remaining cases $u$ begins with $X$ and $v$ begins with $\overline{X}$, so $p$ is a prefix of either $u$ or $v$, and hence a possible prefix of $u$.

Conversely, suppose $u \equiv v$ and $p$ is a possible prefix of $u$. Then exactly one of the six conditions in Lemma 3 applies. By Lemma 2 every word equivalent to $u$ begins with either $XY$ or $\overline{XY}$. Since $p$ is a piece, $X$ is the maximal piece prefix of $XYZ$, and $\overline{X}$ is the maximal piece prefix of $\overline{XY}Z$ it follows that $p$ is a prefix of either $X$ or $\overline{X}$. If any but condition (2) of Lemma 2 is satisfied, this suffices to show that the corresponding condition from the statement of Lemma 3 holds.

If condition (2) from Lemma 3 applies, we must show additionally that either $p$ is a prefix of $X$, or $p$ is a prefix of $\overline{X}$ and $Z$ is a possible prefix of $u'$. Suppose $p$ is not a prefix of $X$. Then by the above, $p$ is a prefix of $\overline{X}$. It follows from Lemma 2 that the only way the prefix $XY$ of the word $u$ can be changed using the defining relations is by application of the relation $(XYZ, \overline{XY}Z)$. In order for this to happen, one must clearly be able to rewrite $u = XYu'$ to a word of the form $XYZw$; consider the shortest possible rewriting sequence which achieves this. By Lemma 2 no term in the sequence except for the last term will contain a relation word overlapping the initial $XY$. It follows that the same rewriting steps rewrite $u'$ to $Zw$, so that $Z$ is a possible prefix of $u'$, as required. □
4. The Algorithm

In this section we present an algorithm, for a fixed monoid presentation satisfying \( C(4) \), which takes as input arbitrary words \( u \) and \( v \) and a piece \( p \), and decides whether \( u \equiv v \) and \( p \) is a possible prefix of \( u \). It will transpire that this algorithm can be implemented to run time in linear in the shorter of \( u \) and \( v \). In particular, by setting \( p = \epsilon \) we obtain an algorithm to solve the word problem in time linear in the smaller of the input words. The algorithm is shown (in recursive/functional pseudocode) in Figure 1. Our first objective is to prove the correctness of the algorithm, that is, that whenever the algorithm terminates, it provides the output it gives is correct.

**Lemma 5.** Suppose \( u \) and \( v \) are words and \( p \) a piece. Then the algorithm \( \text{WP-PREFIX}(u, v, p) \)

- outputs **YES** only if \( u \equiv v \) and \( p \) is a possible prefix of \( u \); and
- outputs **NO** only if \( u \neq v \) or \( p \) is not a possible prefix of \( u \).

**Proof.** We prove correctness using induction on the number \( n \) of recursive calls.

Consider first the base case \( n = 0 \), that is, where the algorithm terminates without a recursive call. Suppose \( u, v \) and \( p \) are such that this happens.

- **Line 3.** If \( u = \epsilon, v = \epsilon \) and \( p = \epsilon \) then clearly \( u \equiv v \) and \( p \) is a possible prefix of \( u \), so the output **YES** is correct.
- **Line 4.** If \( u = \epsilon \) [respectively, \( v = \epsilon \)] then it follows easily from the small overlap condition \( C(4) \) that no relations can be applied to \( u \) [\( v \)]; indeed a relation which could be applied to \( u \) [\( v \)] would have to have \( \epsilon \) as one side, but \( \epsilon \) is a piece and hence cannot be a relation word. Hence, we can have that \( u \equiv v \) and \( p \) is a possible prefix of \( u \) only if \( u = v = p = \epsilon \). In this case, this condition is not satisfied, so the output **NO** is correct.
- **Line 7.** In this case, \( u \) does not begin with a clean overlap prefix of the form \( XY \). So by Proposition 3 every word equivalent to \( u \) must begin with the same letter as \( u \). Hence, if \( u \) and \( v \) do not begin with the same letter then we cannot have \( u \equiv v \), so the output **NO** is correct.
- **Line 9.** Again, \( u \) does not begin with a clean overlap prefix. If \( p \) is non-empty and begins with a different letter to \( u \), then again by Proposition 3 \( p \) cannot be a possible prefix of \( u \), so the output **NO** is correct.
- **Line 13.** We are now in the case that \( u \) has a clean overlap prefix \( XY \). If \( p \) is not a prefix of \( X \) or \( X^{-1} \) then by Lemma 4 we see that \( p \) is not a possible prefix of \( u \), so the output **NO** is correct.
- **Line 21.** Once again, we are in the case that \( u \) has a clean overlap prefix \( XY \). If \( v \) does not begin with either \( XY \) or \( XY^{-1} \) then by Lemma 3 we cannot have \( u \equiv v \) so the output **NO** is correct.
- **Line 43.** We are now in the case that \( u = XYu' \) and \( v = X^{-1}v' \) where \( Z \) is not a prefix of \( u' \) and \( Z \) is not a prefix of \( v' \). We know also that \( z \) is the maximal common suffix of \( Z \) and \( Z \) and \( z_1 \) and \( z_2 \) are such that \( Z = z_1z \) and \( Z = z_2z \). By Lemma 4 we cannot have \( u \equiv v \) unless \( u' \)
WP-Prefix\((u, v, p)\)
1 if \(u = \epsilon\) or \(v = \epsilon\)
2 then if \(u = \epsilon\) and \(v = \epsilon\) and \(p = \epsilon\)
3 then return Yes
4 else return No
5 elseif \(u\) does not have the form \(XYu'\) with \(XY\) a clean overlap prefix
6 then if \(u\) and \(v\) begin with different letters
7 then return No
8 elseif \(p \neq \epsilon\) and \(u\) and \(p\) begin with different letters
9 then return No
10 else
11 \(u \leftarrow u\) with first letter deleted
12 \(v \leftarrow v\) with first letter deleted
13 if \(p \neq \epsilon\)
14 then \(p \leftarrow p\) with first letter deleted
15 return WP-Prefix\((u, v, p)\)
16 else
17 let \(X, Y, u'\) be such that \(u = XYu'\)
18 if \(p\) is a prefix of neither \(X\) nor \(\overline{X}\)
19 then return No
20 elseif \(u = XYu''\) and \(v = XYv''\)
21 then if \(u''\) is \(Z\)-active
22 then return WP-Prefix\((\overline{Z}u'', \overline{Z}v'', \epsilon)\)
23 elseif \(u = XYu''\) and \(v = XYv''\)
24 then return WP-Prefix\((u', v', \epsilon)\)
25 elseif \(u = XYu''\) and \(v = XYv''\)
26 then if \(u''\) is \(Z\)-active
27 then return WP-Prefix\((\overline{Z}u', \overline{Z}v', \epsilon)\)
28 elseif \(u = XYu''\) and \(v = XYv''\)
29 then return WP-Prefix\((u', v'', \epsilon)\)
30 elseif \(u = XYu''\) and \(v = XYv''\)
31 then let \(z\) be the maximal common suffix of \(Z\) and \(\overline{Z}\)
32 let \(z_1\) be such that \(Z = z_1z\)
33 let \(z_2\) be such that \(\overline{Z} = z_2z\)
34 if \(u'\) does not begin with \(z_1\) or \(v'\) does not begin with \(z_2\)
35 then return NO
36 else let \(u''\) be such that \(u' := z_1u''\)
37 let \(v''\) be such that \(v' := z_2v''\)
38 return WP-Prefix\((u'', v'', z)\)

Figure 1. Algorithm for the Word Problem
and \( v' \) have the form \( z_1u'' \) and \( z_2v'' \) respectively, so if this is not the case, the output NO is correct.

Now let \( n > 0 \) and suppose for induction that the algorithm produces the correct output whenever it terminates after strictly fewer than \( n \) recursive calls. Let \( u, v, p \) be such that the algorithm terminates after \( n \) recursive calls. This time, we consider each of the possible places at which the first recursive call can be made, establishing in each case that the output produced is correct.

**Line 24.** We know that \( u = XY Zu'' \), that \( v = XY Zv'' \) and that \( p \) is a prefix of \( X \) or \( \overline{X} \). By Lemma 4 it follows that \( u \equiv v \) and \( p \) is a possible prefix of \( u \) if and only if \( Zu'' \equiv Zv'' \) or \( Zu'' \equiv \overline{Zv''} \). We also know that \( u'' \) is \( Z \)-active, so by Corollary 3 this is true if and only if \( \overline{Zu''} \equiv \overline{Zv''} \).

**Line 25.** This is the same as the previous case, except that \( u'' \) is not \( Z \)-active. In this case, by Proposition 4 we have that \( \overline{Zu''} \equiv \overline{Zv''} \) implies \( u'' \equiv v'' \) which in turn implies \( Zu'' \equiv Zv'' \), so it suffices to test the latter.

**Line 28.** Here we know that \( u = XY u' \), \( v = XY v' \), that \( Z \) is not a prefix of \( u' \) or \( v' \) and that \( p \) is a prefix of \( X \). It follows by Lemma 4 that \( u \equiv v \) and \( p \) is a possible prefix of \( u \) if and only if \( u' \equiv v' \).

**Line 29.** This time we know that \( u = XY u' \), \( v = XY v' \) and that \( p \) is a prefix of \( \overline{X} \) but not of \( X \). It follows by Lemma 4 that \( u \equiv v \) and \( p \) is a possible prefix of \( u \) if and only if \( u' \equiv v' \) and \( Z \) is a possible prefix of \( u' \).

**Line 32.** Here we have \( u = XY Zu'' \) and \( v = \overline{XYZv''} \), and \( p \) is a prefix of \( X \) or \( \overline{X} \). It follows by Lemma 4 that \( u \equiv v \) and \( p \) is a possible prefix of \( u \) if and only if \( Zu'' \equiv Zv'' \) or \( \overline{Zu''} \equiv \overline{Zv''} \). We also know that \( u'' \) is \( Z \)-active, so by Corollary 3 this is true if and only if \( \overline{Zu''} \equiv \overline{Zv''} \).

**Line 33.** This is the same as the previous case, except that \( u'' \) is not \( Z \)-active. In this case, by Proposition 4 we have that \( \overline{Zu''} \equiv \overline{Zv''} \) implies \( u'' \equiv v'' \) which in turn implies \( Zu'' \equiv Zv'' \), so it suffices to test the latter.

**Line 35.** If we get here, we know that \( u = XY u' \), that \( v = \overline{XYZv''} \), that \( Z \) is not a prefix of \( u' \) and that \( p \) is a prefix of \( X \) or \( \overline{X} \); it follows that \( u \equiv v \) and \( p \) is a possible prefix of \( u \) if and only if condition (4') of Lemma 4 holds, that is, if and only if \( u' \equiv Zv'' \). By the inductive hypothesis, the recursive call will correctly establish if this is the case.

**Line 37.** The argument here is symmetric to that for termination at line 35.

**Line 46.** Having got here, we know that \( p \) is a prefix of \( X \) or \( \overline{X} \), that \( u = XY u' \) and \( v = \overline{XY} v' \) where \( Z \) is not a prefix of \( u' \) and \( \overline{Z} \) is not a prefix of
v'. We know also that z is the maximal common suffix of Z and \( Z \) and \( z_1 \) and \( z_2 \) are such that \( Z = z_1z \) and \( Z = z_2z \). Finally, we know that \( u' = z_1u'' \) and \( v' = z_2v'' \). It follows by Lemma 4 that \( u \equiv v \) and \( p \) is a possible prefix of \( z \) if and only if \( u'' \equiv v'' \) and \( z \) is a possible prefix of \( u'' \). By the inductive hypothesis, the recursive call correctly establishes whether this holds.

\[ \square \]

We have now shown that our algorithm produces the correct output whenever it terminates, but we have not yet shown that it always terminates. In fact, the following theorem shows that it does so after only a linear number of recursive calls.

**Lemma 6.** Let \( k \) be the length of the longest maximal piece suffix of a relation word. The number of recursive calls during execution of a call to WP-PREFIX\((u, v, p)\) is bounded above by \((k + 2)|u| + 1\).

**Proof.** For clarity in our analysis, we let \( u_i, v_i \) and \( p_i \) denote the parameters to the \( i \)th recursive call in the execution (with in particular \( u_0 = u \), \( v_0 = v \) and \( p_0 = p \)). Each call to the function involves executing exactly one of the sections 1–4, 6–15 and 17–46; we call these calls of type A, B and C respectively. We shall show that the number of calls of each of these types is bounded above by a linear function of \(|u|\) so that, the total number of recursive calls is also bounded above by a linear function of \(|u|\).

First, notice that a call of type A cannot make a recursive call, so that is only at most one type A call in the execution.

Now for a word \( x \) we let \( r(x) = 0 \) if \( x \) does not have a clean overlap prefix, and \( r(x) \) to be the length of the part of \( x \) which follows the shortest clean overlap prefix, that is, \(|x'|\) where \( x = aXYx' \) with \( aXY \) the shortest clean overlap prefix, otherwise.

It is readily verified that if the \( i \)th recursive call is of type B and itself makes a recursive call then we have \( r(u_{i+1}) = r(u_i) \), while if the \( i \)th recursive call is of type C and itself makes a recursive call then we have \( r(u_{i+1}) < r(u_i) \). Since \( r(u_i) \) can never be negative, it follows that the total number of recursive calls of type C is linearly bounded above by \( r(u_0) + 1 \), which clearly is no more than \(|u_0|\).

Now note that if the \( i \)th recursive call is of type B and itself makes a recursive call then we have \(|u_{i+1}| = |u_i| - 1\), while if the \( i \)th recursive call is of type C and itself makes a recursive call then we have \( r(u_{i+1}) \leq |u_i| + k \).

We have seen that the entire execution cannot feature more than \(|u_0|\) calls of type C or more than one call of type A. Hence, if the execution involves \( i \) recursive calls, it must include at most \(|u_0|\) calls of type C, and at least \( i - |u_0| - 1 \) calls of type B. It follows that, if execution involves \( i \) recursive calls, we must have

\[ |u_i| \leq |u_0| + |u_0|k - (i - |u_0| - 1) = (k + 2)|u| - i + 1 \]

Since the length of \( u_i \) cannot be negative, it follows that execution must terminate after at most \((k + 2)|u| + 1\) calls.

\[ \square \]

It remains to justify our claim that this algorithm can be implemented in linear time. Since the concept of linear time is highly dependant upon
model of computation, it is necessary to be precise upon the model under consideration. We consider a Turing machine with two two-way-infinite read-write storage tapes, using a tape alphabet including the generators for our monoid and a separator symbol #. (Recall that a two-way-infinite tape can be simulated using a one-way-infinite tape in linear time [4, Section 7.5], so the assumption of a two-way-infinite tape is essentially immaterial). If we assume that the input words $u$, $v$ and $p$ are initially encoded on one of the tapes in the form $#u#v#p#$, then it is easily seen that, with a linear amount of preprocessing, we can store the piece $p$ in the finite state control, and arrange for $#u#$ and $#v#$ to be the content of the first and second tape respectively.

It is straightforward to verify that, given a word $u$, one can check whether $u$ has a clean overlap prefix of the form $XY$, and if so find $X$, $Y$ and the corresponding $Z$, by analysing a prefix of $u$ of bounded length. Similarly, for a given maximal piece suffix $Z$, we can check whether $u$ is $Z$-active by analysing a prefix of $u$ of bounded length. It follows that each recursive step of our algorithm involves analysing prefixes of $u$ and $v$ of bounded length, before possibly making a recursive call, with $u$ and $v$ modified only by changing prefixes of bounded length. Clearly any analysis of a bounded length prefix can be performed in constant time; moreover, if a recursive call is required then the tape contents can be modified to contain the parameters for that call, again in constant time. It follows that the algorithm can be implemented with execution time bounded above by a linear function of the number of recursive calls in the execution, which by Lemma 6 is bounded above by a linear function of the length of $u$.

Moreover, by swapping $u$ and $v$ at the start of the computation if necessary, we may assume without loss of generality that $u$ is shorter than $v$. Thus we obtain the following.

**Theorem 1.** For each every monoid presentation satisfying $C(4)$, there exists a two-tape Turing machine which solves the corresponding word problem in time linear in the shorter of the input words.

The reader may initially be surprised by the fact that one can test equivalence of two words in time bounded by a function of the shorter word – indeed, this bound potentially does not even afford time to fully read the longer word! However, Remmers showed that, for a fixed $C(3)$ presentation, the length of the longer of two equivalent words is bounded by a linear function of the length of the shorter [3, Theorem 5.2.14]. Thus, if the difference in lengths of two words is too great, one may conclude without further analysis that the words are not equivalent. In fact Remmers’ result is the only possible explanation for this phenomenon, so the fact that this property holds for $C(4)$ presentations can also be deduced from Theorem 1.

5. Uniform Decision Problems

In Section 4 we developed a linear time algorithm to solve the word problem for a fixed small overlap presentation. Since our method of describing the algorithm was entirely constructive, one might reasonably expect that it also gives rise to a solution for the uniform word problem for $C(4)$ presentations, that is the algorithmic problem of, given a $C(4)$ presentation and
two words, deciding whether the words represent the same element of the
monoid presented. In this section, we shall see that this is indeed the case,
and show that the resulting algorithm remains fast.

To avoid unnecessary technicalities, we describe and analyse the algo-
rithms using the RAM model of computation; in particular this allows us
to assume that elementary operations involving generators from the presen-
tation (such as comparing two generators) are single steps performable in
constant time. The exact time complexity of a Turing machine implemen-
tation would depend upon the number of tapes and the precise encod-
ing of the input, but would certainly remain polynomial of low degree in the input
size.

We begin with some simple results describing the complexity of some
elementary computations with a finite monoid presentation. If \( \langle A \mid R \rangle \) is a
finite presentation we denote by \( |A| \) the cardinality of the alphabet \( A \), and
by \( |R| \) the sum length of the relation words in \( R \). Where the meaning is
clear, we shall abuse notation by using \( R \) also to denote the set of relation
words in the presentation.

**Proposition 6.** There is a RAM algorithm which, given a presentation \( \langle A \mid R \rangle \) and a word \( w \), computes the maximum piece prefix (and/or maximum
piece suffix) of \( w \) in time \( O(|w||R|) \). In particular, there is a RAM algorithm
to decide, given the same input, decides whether the word \( w \) is a piece in
time \( O(|w||R|) \).

**Proof.** For each relation word \( R \in R \) and position \( 1 < i < |R| \) in that word
we can compute in time \( O(|w|) \) the length \( n \) of the longest common prefix
of \( w \) and \( R_i \ldots R_{|R|} \) (where \( R_j \) represents the \( j \)th letter of \( R \)). Our machine
does this for each relation word and each position in that relation word in
turn, recording as it goes along (i) the maximum value of \( n \) attained so far,
and (ii) the maximum value of \( n \) which has been attained or exceeded at
least twice. The latter, upon completion, is clearly the length of the longest
piece prefix of \( w \), and the total time taken for execution is

\[
O \left( \sum_{R \in R} \sum_{i=1}^{|R|} |w| \right) = O(|w||R|)
\]

as claimed. An obvious dual algorithm can be used to find the longest piece
suffix of \( w \). \( \square \)

**Corollary 5.** There is a RAM algorithm which, given as input a presenta-
tion \( \langle A \mid R \rangle \), decides in time \( O(|R|^2) \) whether the presentation satisfies the
condition \( C(4) \).

**Proof.** Our machine begins by computing the maximum piece prefix \( X_R \) and
maximum piece suffix \( Z_R \) for each relation word \( R \in R \); by Proposition 6
this can be done in time

\[
O \left( \sum_{R \in R} |R| |R| \right) = O(|R|^2).
\]

It then tests, in time \( O(|R|) \), whether for any of the relation words \( R \) we
have \( |X_R| + |Z_R| \geq |R| \). If so then some relation word is a product of two
pieces, so the presentation does not even satisfy the weaker condition $C(3)$ and we are done.

Otherwise, the machine computes, again in time $O(|\mathcal{R}|)$, the middle word $Y_R$ of each relation word. By our remarks in Section 1, the presentation satisfies $C(4)$ if and only if none of the words $Y_R$ is a piece. Using Proposition 6 again, this condition can be tested in time

$$O \left( \sum_{R \in \mathcal{R}} |Y_R||\mathcal{R}| \right) = O \left( |\mathcal{R}|^2 \right).$$

Thus, we have described a RAM algorithm to test a presentation $\langle A | R \rangle$ for the $C(4)$ condition in time $O(|\mathcal{R}|^2)$. □

**Theorem 2.** There is a RAM algorithm which, given as input a $C(4)$ presentation $\langle A | R \rangle$ and two words $u, v \in A^*$, decides whether $u$ and $v$ represent the same element of the semigroup presented in time

$$O \left( |\mathcal{R}|^2 \min(|u|, |v|) \right).$$

*Proof.* Suppose we are given a $C(4)$ presentation $\langle A | R \rangle$ and two words $u, v \in A^*$. Just as in the proof of Proposition 6, the machine begins by finding for every relation $R$ the maximum piece prefix $X_R$, the maximum piece suffix $Z_R$ and the middle word $Y_R$, in time $O(|\mathcal{R}|^2)$. It now has the information required to apply the algorithm WP-PREFIX given above. A simple line-by-line analysis shows that each line, and hence each recursive call, can be executed in time $O(|\mathcal{R}|)$. By Lemma 6 the number of recursive calls is bounded above by $(k + 2)|u| + 1$ where $k$, being the length of the longest maximum piece suffix of a relation word, is less than $|\mathcal{R}|$. Thus, this part of the algorithm terminates in time $O(|\mathcal{R}|^2|u|)$.

As above we may assume, by exchanging $u$ and $v$ at the start of the computation if necessary, that $|u| < |v|$ so that $\min(|u|, |v|) = |u|$. It follows that the uniform word problem can be solved in time $O \left( |\mathcal{R}|^2 \min(|u|, |v|) \right)$ as claimed. □
