DIVISIBILITY PROPERTIES OF COEFFICIENTS OF LEVEL $p$
MODULAR FUNCTIONS FOR GENUS ZERO PRIMES

NICKOLAS ANDERSEN AND PAUL JENKINS

ABSTRACT. Lehner’s 1949 results on the $j$-invariant showed high divisibility of the function’s coefficients by the primes $p \in \{2, 3, 5, 7\}$. Expanding his results, we examine a canonical basis for the space of level $p$ modular functions holomorphic at the cusp 0. We show that the Fourier coefficients of these functions are often highly divisible by these same primes.

1. Introduction and Statement of Results

A level $p$ modular function $f(\tau)$ is a holomorphic function on the complex upper half-plane which satisfies

$$f \left( \frac{a\tau + b}{c\tau + d} \right) = f(\tau) \text{ for all } \left( \begin{array}{cc} a & b \\ c & d \end{array} \right) \in \Gamma_0(p)$$

and is meromorphic at the cusps of $\Gamma_0(p)$. Equivalently, $f(\tau)$ is a weakly holomorphic modular form of weight 0 on $\Gamma_0(p)$. Such a function will necessarily have a $q$-expansion of the form $f(\tau) = \sum_{n=n_0}^\infty a(n)q^n$, where $q = e^{2\pi i \tau}$.

Of particular interest in the study of modular forms is the classical $j$-invariant, $j(\tau) = q^{-1} + 744 + \sum_{n=1}^\infty c(n)q^n$, which is a modular function of level 1. The coefficients $c(n)$ of the $j$-function, like the Fourier coefficients of many other modular forms, are of independent arithmetic interest; for instance, they appear as dimensions of a special graded representation of the Monster group.

In 1949 Lehner showed [7, 8] that

$$c(2^a 3^b 5^c 7^d n) \equiv 0 \pmod{2^{3a} 3^{2b} 5^{3c} 7^{d+1}}$$

proving that the coefficients $c(n)$ are often highly divisible by small primes. Similar results have recently been proven for other modular functions in [5], and for modular forms of level 1 and small weight in [4, 3]. It is natural to ask whether such congruences hold for the Fourier coefficients of modular functions of higher level, such as those studied by Ahlgren [1] in his work on Ramanujan’s $\theta$-operator.

Lehner’s results for $j(\tau)$ are in fact more general; in [8] he pointed out that for $p = 2, 3, 5, 7$, similar congruences hold for the coefficients of level $p$ modular functions which have integral coefficients at both cusps and have poles of order less than $p$ at the cusp at infinity.

In this paper, for $p \in \{2, 3, 5, 7\}$, we examine canonical bases for spaces of level $p$ modular functions which are holomorphic at the cusp 0. To construct these bases,
we introduce the level \( p \) modular function \( \psi^{(p)}(\tau) \), defined as

\[
\psi^{(p)}(\tau) = \left( \frac{\eta(\tau)}{\eta(p\tau)} \right)^{24/p-1} \text{ where } \eta(\tau) = q^{\frac{1}{24}} \prod_{n=1}^{\infty} (1 - q^n).
\]

The integer \( 24/p \) for \( p = 2, 3, 5, 7 \) will appear frequently, so we will denote it \( \lambda(p) \), or simply \( \lambda \) where no confusion arises. The function \( \psi^{(p)}(\tau) \) is a modular function of level \( p \) with a simple pole at \( \infty \) and a simple zero at 0. We will also use the modular function

\[
\phi^{(p)}(\tau) = (\psi^{(p)}(\tau))^{-1}.
\]

Following Ahlgren [1], and using the notation of Duke and Jenkins [5], for \( p = 2, 3, 5, 7 \) we construct a basis \( \{f_{0,m}^{(p)}(\tau)\}_{m=0}^{\infty} \) for the space of level \( p \) modular functions which are holomorphic at 0 as follows:

\[
f_{0,0}^{(p)}(\tau) = 1,
\]

\[
f_{0,m}^{(p)}(\tau) = q^{-m} + O(1) = \psi^{(p)}(\tau)^m - Q(\psi^{(p)}(\tau)),
\]

where \( Q(x) \) is a polynomial of degree \( m - 1 \) with no constant term, chosen to eliminate all negative powers of \( q \) in \( \psi^{(p)}(\tau)^m \) except for \( q^{-m} \). Since \( \psi^{(p)}(\tau) \) vanishes at 0 and the polynomial \( Q \) has no constant term, we see that the functions \( f_{0,m}^{(p)} \) also vanish at 0 when \( m > 0 \). We write

\[
f_{0,m}^{(p)} = q^{-m} + \sum_{n=0}^{\infty} a_0^{(p)}(m, n) q^n
\]

so that for \( n \geq 0 \), the symbol \( a_0^{(p)}(m, n) \) denotes the coefficient of \( q^n \) in the \( m \)th basis element of level \( p \). Note that the function \( f_{0,m}^{(p)} \) corresponds to Ahlgren’s \( j_m^{(p)} \).

For an example of some of these functions, consider the case \( p = 2 \):

\[
f_{0,1}^{(2)}(\tau) = \psi^{(2)}(\tau) = q^{-1} - 24 + 276q - 2048q^2 + 11202q^3 - 49152q^4 + \ldots
\]

\[
f_{0,2}^{(2)}(\tau) = \psi^{(2)}(\tau)^2 + 48\psi^{(2)}(\tau) = q^{-2} - 24 - 4096q + 98580q^2 - 1228800q^3 + 10745856q^4 + \ldots
\]

\[
f_{0,3}^{(2)}(\tau) = \psi^{(2)}(\tau)^3 + 72\psi^{(2)}(\tau)^2 + 900\psi^{(2)}(\tau) = q^{-3} - 96 + 33606q - 1843200q^2 + 43434816q^3 - 648216576q^4 + \ldots
\]

The function \( f_{0,m}^{(p)} \) is a level \( p \) modular function that vanishes at 0 (if \( m \neq 0 \)) and has a pole of order \( m \) at \( \infty \). The conditions at the cusps determine this function uniquely; if two such functions exist, their difference is a holomorphic modular function, which must be a constant. Since both functions vanish at 0, this constant must be 0.

The functions comprising these bases for \( p = 2, 3, 5, 7 \) have divisibility properties which bear a striking resemblance to the divisibility properties of \( j(\tau) \); in many cases they are identical. As an example of some of the divisibility properties we encounter with this basis, we experimentally examine the 2-adic valuation of the even indexed coefficients of \( f_{0,m}^{(2)}(\tau) \) for \( m = 1, 3, 5, 7 \) in Table [1]. As the data in the table suggest, the 2-divisibility which \( j(\tau) \) exhibits gives us a lower bound on the 2-divisibility of the odd-indexed \( p = 2 \) basis elements.
Note that these functions form a basis for $M^\infty_0(p)$, the space of modular forms of weight 0 and level $p$ with poles allowed only at the cusp at $\infty$. A full basis for the space $M^!_0(p)$ of weakly holomorphic modular forms of weight 0 and level $p$ is generated by the $f_{0,m}(\tau)$ and the functions $(\phi(p)(\tau))^n$ for integers $n \geq 1$.

Recall that the concluding remarks of Lehner’s second paper state that the coefficients of certain level $p$ modular functions having a pole of order less than $p$ at $\infty$ have the same $p$-divisibility properties as the coefficients $c(n)$ of $j(\tau)$. More precisely, we have the following theorem.

**Theorem 1** (Lehner). Let $p \in \{2, 3, 5, 7\}$ and let $f(\tau)$ be a modular function on $\Gamma_0(p)$ having a pole at $\infty$ of order $< p$ and $q$-series of the form

$$f(\tau) = \sum_{n=n_0}^{\infty} a(n)q^n,$$

$$f(-1/pr) = \sum_{m=m_0}^{\infty} b(n)q^n,$$

where $a(n), b(n) \in \mathbb{Z}$. Then the coefficients $a(n)$ satisfy the following congruence properties:

- $a(2^n n) \equiv 0 \pmod{2^{2n+8}}$ if $p = 2$
- $a(3^n n) \equiv 0 \pmod{3^{2n+3}}$ if $p = 3$
- $a(5^n n) \equiv 0 \pmod{5^{n+1}}$ if $p = 5$
- $a(7^n n) \equiv 0 \pmod{7^n}$ if $p = 7$.

Note that Lehner’s original statement of this theorem mistakenly states that a function on $\Gamma_0(p)$ inherits the $p$-divisibility property for every prime in $\{2, 3, 5, 7\}$, not just the prime matching the level.

A necessary condition in the statement of Lehner’s theorem is that the function must have an integral $q$-expansion at 0. This condition is quite strong: in fact, neither the function $\phi(p)(\tau)$ nor any of its powers satisfy it, although the functions $f_{0,m}(\tau)$ do.
Further, Lehner’s theorem assumes that the order of the pole at \(\infty\) must be less than \(p\). In this paper, we remove this restriction on the order of the pole to show that every function in the \(f_{0,m}^{(p)}\) basis has divisibility properties similar to those in Theorem 1. Specifically, we prove the following theorem.

**Theorem 2.** Let \(p \in \{2, 3, 5, 7\}\), and let

\[
f_{0,m}^{(p)}(\tau) = q^{-m} + \sum_{n=0}^{\infty} a_0^{(p)}(m,n)q^n
\]

be an element of the basis described above, with \(m = p^\alpha m'\) and \((m', p) = 1\). Then, for \(\beta > \alpha\),

\[
a_0^{(2)}(2^\alpha m', 2^\beta n) \equiv 0 \pmod{2^{3(\beta-\alpha)+8}} \quad \text{if } p = 2
\]

\[
a_0^{(3)}(3^\alpha m', 3^\beta n) \equiv 0 \pmod{3^{2(\beta-\alpha)+3}} \quad \text{if } p = 3
\]

\[
a_0^{(5)}(5^\alpha m', 5^\beta n) \equiv 0 \pmod{5(\beta-\alpha)+1} \quad \text{if } p = 5
\]

\[
a_0^{(7)}(7^\alpha m', 7^\beta n) \equiv 0 \pmod{7^{(\beta-\alpha)}} \quad \text{if } p = 7.
\]

Note that for basis elements \(f_{0,m}^{(p)}\) with \((m, p) = 1\), these divisibility properties match those in Theorem 1; in fact, Lehner’s proof is easily extended to prove the congruences in these cases. For basis elements with \(m = p^\alpha m'\) and \(\alpha \geq 1\), the divisibility is “shifted.” This shifting occurs in the \((\beta - \alpha)\) factor in the exponent of the modulus.

For the coefficients \(a_0^{(p)}(p^\alpha m', p^\beta n)\) with \(\alpha > \beta\), computations suggest that similar congruences should hold. Additionally, it appears that powers of the function \(\varphi^{(p)}(\tau)\) have Fourier coefficients with slightly weaker divisibility properties, despite the fact that their Fourier coefficients at 0 are not integral. It would be interesting to more fully understand these congruences.

## 2. Preliminary Lemmas and Definitions

In this section, we provide the necessary definitions and background for the proof of the main theorem.

For a prime \(p\) we define the level \(p\) Hecke operator \(U_p\) by

\[
U_p f(\tau) = \frac{1}{p} \sum_{\ell=0}^{p-1} f(\tau + \ell) - \ell \pmod{p},
\]

using the notation \(U_p^n f = U_p U_p \cdots U_p f\) for repeated application of \(U_p\). When \(f\) has the Fourier expansion \(f(\tau) = \sum_{n=n_0}^{\infty} a(n)q^n\), this operator takes the form

\[
U_p f(\tau) = \sum_{n=n_0}^{\infty} a(pn)q^n,
\]

essentially “pulling out” all of the coefficients of \(f\) whose index is divisible by \(p\). This operator preserves modularity: if \(f\) is a level \(p\) modular function, then \(U_p f\) is also a level \(p\) modular function.

For the primes \(p = 2, 3, 5, 7\) the topological genus of \(\Gamma_0(p)\backslash \mathcal{H}\) is zero, so the field of level \(p\) modular functions is generated by a single modular function called a Hauptmodul. For the primes in consideration, one such function is \(\psi^{(p)}(\tau)\). Note that the modular function \(\phi^{(p)}(\tau) = \psi^{(p)}(\tau)^{-1} = q + O(q^2)\) is also a Hauptmodul.
Further, for these primes, the fundamental domain for $\Gamma_0(p)$ has precisely two cusps, which may be taken to be at $\infty$ and at 0. Hence, we are most concerned with the behavior of these functions at $\infty$ and at 0. To switch between cusps, we make the substitution $\tau \mapsto -1/pr$. The following lemma gives relations for $\psi^{(p)}(\tau)$ and $\phi^{(p)}(\tau)$ at 0, and makes clear that powers of $\phi^{(p)}$ do not satisfy Lehner’s integrality condition.

**Lemma 3.** The functions $\psi^{(p)}(\tau)$ and $\phi^{(p)}(\tau)$ satisfy the relations

\[
\begin{align*}
\psi^{(p)}(-1/pr) &= p^{\lambda/2} \phi^{(p)}(\tau) \\
\phi^{(p)}(-1/pr) &= p^{-\lambda/2} \psi^{(p)}(\tau)
\end{align*}
\]

*Proof.* The functional equation for $\eta(\tau)$ is $\eta(-1/\tau) = \sqrt{-i\tau}\eta(\tau)$. Using this, we find that

\[
\psi^{(p)}\left(-\frac{1}{pr}\right) = \left(\frac{\eta(-1/pr)}{\eta(-1/\tau)}\right) = \left(\frac{\sqrt{-i\tau}\eta(pr)}{\sqrt{-i\tau}\eta(\tau)}\right) = (\sqrt{pr})^\lambda \left(\frac{\eta(pr)}{\eta(\tau)}\right) = p^{\lambda/2} \phi^{(p)}(\tau).
\]

The second statement follows after replacing $\tau$ by $-1/pr$ in the first statement. $\Box$

We next state a well-known lemma which gives a formula for determining the behavior of a modular function at 0 after $U_p$ has been applied. A proof can be found in [2].

**Lemma 4.** Let $p$ be prime and let $f(\tau)$ be a level $p$ modular function. Then

\[
(2.3) \quad p(U_p f)(-1/pr) = p(U_p f)(pr) + f(-1/p^2\tau) - f(\tau).
\]

Lehner’s original papers included the following lemma and its proof, which gives two important equations. The first gives a formula for $U_p \phi^{(p)}$ as a polynomial with integral coefficients in $\phi^{(p)}$; the second gives an algebraic relation which is satisfied by $\phi^{(p)}(\tau/p)$.

**Lemma 5.** Let $p \in \{2, 3, 5, 7\}$. Then there exist integers $b_j^{(p)}$ such that

\[
(a) \quad U_p \phi^{(p)}(\tau) = p \sum_{j=1}^{p} b_j^{(p)} \phi^{(p)}(\tau)^j.
\]

Further, let $h^{(p)}(\tau) = p^{\lambda/2} \phi^{(p)}(\tau/p)$. Then

\[
(b) \quad (h^{(p)}(\tau))^p + \sum_{j=1}^{p} (-1)^j g_j(\tau)(h^{(p)}(\tau))^{p-j} = 0
\]

where $g_j(\tau) = (-1)^{j+1} p^{\lambda/2+2} \sum_{\ell=j}^{P} b_{\ell} \phi^{(p)}(\tau)^{\ell-j+1}$.

*Proof.* (a) Since $\phi$ vanishes at $\infty$, $U_p \phi$ also vanishes at $\infty$; we will now consider its behavior at 0. Using (2.3) and replacing $\tau$ by $pr$ in (2.1) we obtain

\[
U_p \phi(-1/pr) = U_p \phi(pr) + p^{-1} \phi(-1/p^2\tau) - p^{-1} \phi(\tau) = U_p \phi(pr) + \psi(pr) - p^{-1} \phi(\tau) = O(q^p) + p^{-\lambda/2-1}q^{-p} + O(1) - p^{-1}q + O(q^2)
\]

\[
p^{\lambda/2+1}U_p \phi(-1/pr) = q^{-p} + O(1)
\]
The right side of this equation is a level $p$ modular function with integer coefficients, so we may write it as a polynomial in $\psi(\tau)$ with integer coefficients. The polynomial will not have a constant term since the left side vanishes at 0. Therefore,

$$p^{\lambda/2+1}U_p \phi(-1/p\tau) = \sum_{j=1}^{p} c_j \psi(\tau)^j.$$ 

Now, replacing $\tau$ by $-1/p\tau$, we find

$$p^{\lambda/2+1}U_p \phi(\tau) = \sum_{j=1}^{p} c_j p^{\lambda/2} \phi(\tau)^j.$$ 

After cancelling the $p^{\lambda/2+1}$, we find that $U_p \phi(\tau) = \sum_{j=1}^{p} c'_j \phi(\tau)^j$ and we compute the coefficients $c'_j$ (the authors used MATHEMATICA). The computation is finite, and we find that each coefficient $c'_j$ has a factor of $p$, so the coefficients $b^{(p)}_j$ are integral. A complete table of values of the $b^{(p)}_j$ is found in Table 2.

| $p$ | 2   | 3   | 5   | 7   |
|-----|-----|-----|-----|-----|
| 1   | $3 \cdot 2^2$ | $10 \cdot 3^1$ | $63 \cdot 5^0$ | $82 \cdot 7^0$ |
| 2   | $2^{10}$ | $4 \cdot 3^6$ | $52 \cdot 5^3$ | $176 \cdot 7^2$ |
| 3   | $3^{10}$ | $63 \cdot 5^5$ | $845 \cdot 7^3$ |
| 4   | $6 \cdot 5^8$ | $272 \cdot 7^5$ |
| 5   | $5^{10}$ | $46 \cdot 7^7$ |
| 6   |     | $4 \cdot 7^9$ |
| 7   |     | $7^{10}$ |

Table 2. Values of $b^{(p)}_j$

(b) We again apply (2.3) to $\phi(\tau)$, this time using what we know from (a).

$$pU_p \phi(-1/p\tau) = pU_p \phi(p\tau) + \phi(-1/p^2\tau) - \phi(\tau)$$

$$p^2 \sum_{j=1}^{p} b_j \phi(-1/p\tau)^j = p^2 \sum_{j=1}^{p} b_j \phi(p\tau)^j + \phi(-1/p^2\tau) - \phi(\tau).$$

We now use Lemma 3 with the knowledge that $\psi(\tau) = \phi(\tau)^{-1}$ to obtain

$$p^2 \sum_{j=1}^{p} b_j p^{-\lambda/2} \phi(\tau)^{-j} - p^2 \sum_{j=1}^{p} b_j \phi(p\tau)^j + \phi(\tau) - p^{-\lambda/2} \phi(p\tau)^{-1} = 0.$$ 

After replacing $\tau$ by $\tau/p$ and multiplying by $p^{\lambda/2}$, this becomes

$$p^{\lambda/2+2} \sum_{j=1}^{p} b_j \left( h(\tau)^{-j} - \phi(\tau)^j \right) + h(\tau) - \phi(\tau)^{-1} = 0.$$
We now divide by $h^{-1} - \phi$. Note two facts:

\[
h^{-j} - \phi^j = (h^{-1} - \phi) \sum_{\ell=0}^{j-1} h^{-\ell} \phi^{j-\ell-1}
\]

\[
\frac{h - \phi^{-1}}{h^{-1} - \phi} = \frac{h(h\phi - 1)}{\phi(1-h\phi)} = -\frac{h}{\phi}.
\]

So (2.4) becomes

\[
p^{\lambda/2 + 2} \sum_{j=1}^{p} b_j \sum_{\ell=0}^{j-1} h^{-\ell} \phi^{j-\ell-1} - \phi^{-1} h = 0
\]

which, after multiplying by $\phi h^{p-1}$, becomes

\[
p^{\lambda/2 + 2} \sum_{j=1}^{p} b_j \sum_{\ell=0}^{j-1} h^{\ell} \phi^{j-\ell-1} - h^p = 0.
\]

We now change the order of summation and rearrange terms to obtain the desired formula:

\[
h(\tau)^p = \sum_{j=1}^{p} (p^{\lambda/2 + 2} \sum_{\ell=j}^{p} b_\ell \phi(\tau)^{\ell-j+1}) h(\tau)^{p-j}.
\]

The next lemma states that when you apply $U_p$ to a certain type of polynomial in $\phi_p$, you get a similar polynomial back which has picked up a power of $p$. The details of this lemma are found in both [7] and [8], scattered throughout the proofs of the main theorems. For our purposes, it will be more useful in the following form.

**Lemma 6.** Let $p \in \{2, 3, 5, 7\}$ and let $R^{(p)}$ denote the set of polynomials in $\phi^{(p)}$ of the form

\[
d_1 \phi^{(p)}(\tau) + \sum_{n=2}^{N} d_n \gamma \phi^{(p)}(\tau)^n
\]

where $\gamma = \begin{cases} 8(n-1) & \text{if } p = 2 \\ 4(n-1) & \text{if } p = 3 \\ n & \text{if } p = 5 \\ n & \text{if } p = 7. \end{cases}$

Then $U_p$ maps $R^{(p)}$ to $p^{\delta} R^{(p)}$ where $\delta = 3, 2, 1, 1$ for $p = 2, 3, 5, 7$, respectively. That is, applying $U_p$ to a polynomial of the above form yields a polynomial of the same form with an extra factor of $p^\delta$.

**Proof.** Consider the function

\[
d_1 U_p \phi(\tau) + \sum_{n=2}^{r} d_n \gamma U_p \phi(\tau)^n.
\]

For the first term, Lemma 6(a) shows that $U_p \phi(\tau) \in p^{\delta} R_p$ since, by inspection, the $b_j$ integers are divisible by sufficiently high powers of $p$.

For the remaining terms, we will prove

\[(2.5) \quad p^\gamma U_p \phi^n = p^\delta r\]
where \( r \in R_p \). The result will immediately follow.

By the definition of \( U_p \) we have

\[
U_p \phi^n = p^{-1} \sum_{\ell=0}^{p-1} \phi \left( \frac{\tau + \ell}{p} \right)^n = p^{-1-\lambda/2} \sum_{\ell=0}^{p-1} h_{\ell}(\tau)^n
\]

where \( h_{\ell}(\tau) = p^{\lambda/2} \phi \left( \frac{\tau + \ell}{p} \right) \) is related to \( h \) from Lemma 5. Let \( S_n \) be the sum of the \( n \)th powers of the \( h_{\ell} \) so that

\[
S_n = \sum_{\ell=0}^{p-1} h_{\ell}^n.
\]

We now use (2.7) to calculate \( S_1 \) and \( S_2 \):

\[
S_1 = g(1)
\]

\[
S_2 = g_1 S_1 - 2g_2 = g^2 - 2g_2.
\]

From Lemma 5 we can compute the values of the \( g_j \). Using the \( b_j \) values from the table in that lemma, we have

\[
g_1 = 2^{14} (b_1 \phi_2 + b_2 \phi_2^2) = 2^{16} (3 \phi_2 + 2^8 \phi_2^2)
\]

\[
g_2 = -2^{14} b_2 \phi_2 = -2^{24} \phi_2.
\]

We can now see that

\[
S_1 = g_1 = 2^{16} (3 \phi_2 + 2^8 \phi_2^2)
\]

\[
S_2 = 2^{32} (3 \phi_2 + 2^8 \phi_2^2)^2 + 2^{25} \phi_2 = 2^{20} (2^5 \phi_2 + 2^{12} 3^2 \phi_2 + 2^{21} 3 \phi_2 + 2^{28} \phi_2^4).
\]

Thus (2.8) is satisfied for \( n = 1, 2 \). We proceed by induction. Assume (2.8) is satisfied for all integers \( < n \). We show that it is satisfied for \( n \). For ease of computation, we introduce the set

\[
R^* = 2^8 R^{(2)} = \left\{ \sum_{i=1}^{m} d_i 2^{8i} \phi_2^i \Big| d_i \in \mathbb{Z}, m \in \mathbb{Z}^+ \right\}
\]

which, the reader will notice, is a ring. From (2.7) we obtain

\[
S_n = g_1 S_{n-1} - g_2 S_{n-2} = 2^8 r_1^* \cdot 2^{4n} r_2^* + 2^{16} r_3^* \cdot 2^{4(n-1)} r_4^* = 2^{4n+8} r_5^* = 2^{4n+16} r.
\]
where \( r^*_i \in R^* \) and \( r \in R^{(2)} \).

**Case 2.** \( p = 3 \). We want to show

\[
S_n = 3^{2n+7} r
\]
where \( r \in R^{(3)} \). We compute the \( g_j \) and \( S_n \) as follows, using the \( b_j \) from the table:

\[
g_1 = 3^3 (3^9 \phi_3^3 + 3^5 4 \phi_3^2 + 10 \phi_3), \quad g_2 = 3^{14} (-3^4 \phi_3^2 - 4 \phi_3), \quad g_3 = 3^{18} \phi_3,
\]

\[
S_1 = g_1, \quad S_2 = g_1^2 - 2g_2, \quad S_3 = g_1^3 - 3g_1g_2 + 3g_3.
\]

From this, we obtain

\[
S_1 = 3^9 (3^9 \phi_3^3 + 3^5 4 \phi_3^2 + 10 \phi_3), \quad S_2 = 3^{14} (8 \phi_3 + 3^3 34 \phi_3^2 + 3^8 80 \phi_3^3 + 3^{13} 68 \phi_3^4 + 3^{18} 8 \phi_3^5 + 3^{25} \phi_3^6), \quad S_3 = 3^{19} (\phi_3 + 3^5 40 \phi_3^2 + 3^8 1174 \phi_3^3 + 3^{15} 136 \phi_3^4 + 3^{18} 581 \phi_3^5 + 3^{25} 16 \phi_3^6 + 3^{27} 58 \phi_3^7 + 3^{32} 4 \phi_3^8 + 3^{35} \phi_3^9)
\]

which proves \((2.9)\) for \( n = 1, 2, 3 \). For the inductive step, let \( R^* \) be the ring \( 3^4 R^{(3)} \) so that

\[
S_n = g_1 S_{n-1} - g_2 S_{n-2} + g_3 S_{n-3} = 3^5 r^*_1 3^{2n+1} r^*_2 + 3^{10} r^*_3 3^{2n-1} r^*_4 + 3^{14} r^*_5 3^{2n-3} r^*_6 = 3^{2n+6} r^*_7 = 3^{2n+10} r,
\]

where \( r^*_i \in R^* \) and \( r \in R^{(3)} \).

**Case 3.** \( p = 5 \). We want

\[
S_n = 5^{2n+2} r
\]
where \( r \in R^{(5)} \). Computing the \( S_n \) we find

\[
S_1 = 5^5 r_1 \quad S_2 = 5^8 r_2 \quad S_3 = 5^{10} r_3 \quad S_4 = 5^{13} r_4 \quad S_5 = 5^{16} r_5
\]

for some \( r_1, \ldots, r_5 \in R^{(5)} \). This proves \((2.10)\) for \( n = 1, \ldots, 5 \). For the inductive step, let \( R^* \) be the ring \( 5^5 R^{(5)} \) so that

\[
S_n = g_1 S_{n-1} - g_2 S_{n-2} + g_3 S_{n-3} - g_4 S_{n-4} + g_5 S_{n-5} = 5^4 r^*_1 5^{2n+1} r^*_2 - \ldots + 5^{14} r^*_9 5^{2n-9} r^*_10 = 5^{2n+3} r^*_11 = 5^{2n+4} r
\]

where \( r^*_i \in R^* \) and \( r \in R^{(5)} \).

**Case 4.** \( p = 7 \). We want

\[
S_n = 7^{n+2} r
\]
where \( r \in R^{(7)} \). Computing the \( S_n \) we find

\[
S_1 = 7^4 r_1 \quad S_2 = 7^6 r_2 \quad S_3 = 7^7 r_3 \quad S_4 = 7^9 r_4 \quad S_5 = 7^{11} r_5 \quad S_6 = 7^{13} r_6 \quad S_7 = 7^{15} r_7
\]
for some \( r_1, \ldots, r_7 \in R^{(7)} \). This proves \([2.11]\) for \( n = 1, \ldots, 7 \). For the inductive step, let \( R^* \) be the ring \( 7R^{(7)} \) so that

\[
S_n = \sum_{i=1}^{7} (-1)^{i+1} y_i S_{n-i}
= r_1^* + \cdots + r_7^* + r_{14}^*
= 7n+4r^*
\]

where \( r_i^* \in R^* \) and \( r \in R^{(7)} \).

\[\square\]

3. Proof of the Theorem

To remind the reader of the main result of the paper, we include it here.

**Theorem.** Let \( p \in \{2, 3, 5, 7\} \), and let \( f_{0,m}^{(p)}(\tau) = q^{-m} \sum a_0^{(p)}(m,n)q^n \) be an element of the basis described above, with \( m = p^\alpha m' \) and \( (m',p) = 1 \). Then, for \( \beta > \alpha \),

\[
\begin{align*}
a_0^{(2)}(2^\alpha m', 2^\beta n) &\equiv 0 \pmod{2^{3(\beta-\alpha)+8}} \quad \text{if } p = 2 \\
a_0^{(3)}(3^\alpha m', 3^\beta n) &\equiv 0 \pmod{3^{2(\beta-\alpha)+3}} \quad \text{if } p = 3 \\
a_0^{(5)}(5^\alpha m', 5^\beta n) &\equiv 0 \pmod{5^{(\beta-\alpha)+1}} \quad \text{if } p = 5 \\
a_0^{(7)}(7^\alpha m', 7^\beta n) &\equiv 0 \pmod{7^{(\beta-\alpha)}} \quad \text{if } p = 7.
\end{align*}
\]

The proof is in three cases. The first illustrates the method for the simplest basis elements, namely those with \((m,p) = 1\). The second demonstrates the “shifting” property at its first occurrence, \( f_{0,p}^{(p)} \). The third is the general case; it builds inductively upon the methods of the first two cases.

3.1. **Case 1:** \((m,p) = 1\).

**Proof.** This proof is almost identical to Lehner’s proof of Theorem 3 in [3], however it applies not only to functions which have poles of order bounded by \( p \), but to all basis elements with \((m,p) = 1\). For ease of notation, let \( f(\tau) = f_{0,m}^{(p)}(\tau) \).

We will demonstrate the method with \( m = 1 \), then generalize it to all \( m \) relatively prime to \( p \). First, we will write \( U_p f(\tau) \) as a polynomial in \( \phi(\tau) \) with integral coefficients, all of which are divisible by the desired power of \( p \). Since \( U_p \) isolates the coefficients whose index is divisible by \( p \), we will have proven the theorem for \( \beta = 1 \). We will then apply \( U_p \) repeatedly to the polynomial, showing that the result is always another polynomial in \( \phi \) with integral coefficients, all of which are divisible by the desired higher power of \( p \).

Consider the level \( p \) modular function \( g(\tau) = pU_p f(\tau) + p^{\lambda/2} \phi(\tau) \). Notice that \( g(\tau) \) is holomorphic at \( \infty \) since both \( U_p f(\tau) \) and \( \phi(\tau) \) are holomorphic there. The \( q \)-expansion at 0 for \( g(\tau) \) is given by

\[
g(-1/p\tau) = p(U_p f)(-1/p\tau) + p^{\lambda/2} \phi(-1/p\tau)
\]

which, by Lemmas [3] and [4] becomes

\[
g(-1/p\tau) = p(U_p f)(p\tau) + f(-1/p^2\tau) - f(\tau) + \psi(\tau).
\]
When we notice that $f(\tau) = \psi(\tau)$ in this $m = 1$ case, we obtain
\[ g(-1/pr) = p(U_pf)(pr) + \psi(-1/p^2r) - \psi(\tau) + \psi(\tau) = p(U_pf)(pr) + p^3\phi(pr), \]
which is holomorphic at $\infty$. Hence, $g(\tau)$ is a holomorphic modular function on $\Gamma_0(p)$, so it must be constant. Therefore,
\[ (3.1) \quad U_pf(\tau) = c_0 - p^{\lambda/2 - 1}\phi(\tau) \]
for some constant $c_0$. The proof is complete for $\beta = 1$.

Note: the prime 13, having genus zero, would work in this construction; however, in that case $\lambda = \frac{24}{13-1} = 2$, so $13^{\lambda/2 - 1} = 1$, and we gain no new information.

We now iterate the above process to prove the theorem for $\beta > 1$. Notice that
\[ U_p(U_pf(\tau)) = c(p) - p^{\lambda/2 - 1}U_p\phi(\tau). \]
We know from Lemma 5 that $U_p\phi$ is a polynomial in $\phi$; in fact, by inspection of the $b_j(p)$ values we see that we may write
\[
\begin{align*}
U_2\phi(2)(\tau) &= 2^3(d_1(2)\phi(2)(\tau) + \sum_{n=2}^{2} d_n(2)2^{8(n-1)}\phi(2)(\tau)^n) \\
U_3\phi(3)(\tau) &= 3^2(d_1(3)\phi(3)(\tau) + \sum_{n=2}^{3} d_n(3)3^{4(n-1)}\phi(3)(\tau)^n) \\
U_5\phi(5)(\tau) &= 5(d_1(5)\phi(5)(\tau) + \sum_{n=2}^{5} d_n(5)5^n\phi(5)(\tau)^n) \\
U_7\phi(7)(\tau) &= 7(d_1(7)\phi(7)(\tau) + \sum_{n=2}^{7} d_n(7)7^n\phi(7)(\tau)^n)
\end{align*}
\]
for some integers $d_n(p)$. This shows that the second $U_p$ iteration is divisible by the correct power of $p$. Further, it gives us a polynomial of a suitable form to iterate the process using Lemma 6. In each of the polynomials above, notice that $U_p\phi(\tau) = p^r r$ for some $r \in \mathbb{R}^p$. Using Lemma 6, we find that
\[ U_p(U_p\phi)(\tau) = p^{2r}r' \]
for some $r' \in \mathbb{R}^p$, and further
\[ U_p^3\phi(\tau) = p^{3r}\phi(\beta) \]
for some $r_\beta \in \mathbb{R}^p$. This completes the proof for $m = 1$.

Now, if $(m, p) = 1$, then $U_pf(\tau)$ is holomorphic at $\infty$, just as it was with $m = 1$. Moving to the cusp at 0 we find that $(U_pf)(-1/pr)$ can be written as a polynomial in $\psi(\tau)$ which appears as a polynomial in $\phi(\tau)$ when we return to $\infty$. Similar to (3.1), we obtain the equality
\[ U_pf(\tau) = c_0 + \sum_{i=1}^{M} p^{\lambda_i/2 - 1}c_i\phi(\tau)^i \]
for some $c_i \in \mathbb{Z}$ and $M \in \mathbb{Z}^+$. The only difference between this equation and (3.1) is that in this more general case, we find that $U_pf$ is a higher degree polynomial in $\phi$. This formula can easily be iterated as before to obtain the desired result. □
3.2. Case 2: \( m = p \).

Proof. Again, for ease of notation, denote \( f^{(p)}(\tau) \) by \( f(\tau) \). For the \( m = p \) case, we will proceed as before; however, we will find that \( U_p f(\tau) \) has poles at both \( \infty \) and 0, and that \( U_p f(\tau) \) does not possess any interesting divisibility properties, but \( U_p^2 f(\tau) \) does. This property will manifest itself as the “shifting” previously mentioned.

Notice first that \( U_p f(\tau) = q^{-1} + O(1) \) has a simple pole at \( \infty \). Therefore, we shall deal primarily with the function \( U_p f(\tau) - \psi(\tau) \), which is holomorphic at \( \infty \). We can use Lemmas 3 and 4 to view this function at 0:

\[
p(U_p f)(-1/pr) - p\psi(-1/pr) = p(U_p f)(pr) + f(-1/p^2r) - f(\tau) - p^{\lambda/2+1}\phi(\tau)
\]

\[
= pq^{-p} + O(1) + O(1) - q^{-p} + O(1) + O(q)
\]

\[
= c_0 + \sum_{i=1}^p c_i\psi(\tau)^i
\]

for some integers \( c_i \). Replacing \( \tau \) by \(-1/pr\), we obtain

\[
(Up f)(\tau) = \frac{c_0}{p} + \psi(\tau) + \sum_{i=1}^p c_i p^{\lambda_i/2-1}\phi(\tau)^i.
\]

The \( \psi(\tau) \) term in the equation makes any attempt at \( p \)-divisibility fail; for example, computation shows that the \( \tau \)-th coefficient of \( \psi^{(2)}(\tau) \) is odd. However, \( \psi(\tau) \) satisfies Lehner’s divisibility properties, so \( U_p f \) inherits its \( p \)-divisibility from \( \psi(\tau) \). So the function

\[
U_p^2 f(\tau) = c_0 + U_p \psi(\tau) + \sum_{i=1}^p c_i p^{\lambda_i/2-1}U_p \phi(\tau)^i
\]

has the same \( p \)-divisibility as \( f^{(p)}_0 \); hence, the shift. \( \square \)

3.3. Case 3: \( m = p^\ell m' \).

Proof. We prove this case using induction on \( \alpha \). Case 1 showed that the theorem is true for all \( m' \) relatively prime to \( p \), so the \( \alpha = 0 \) base case is complete. Assume Theorem 2 holds for all \( m \) of the form \( m = p^\ell m' \) with \( \ell < \alpha \). We will show it holds for \( m = p^\alpha m' \). To simplify notation, let \( f_\alpha(\tau) = f^{(p)}_{0,p^\ell m'}(\tau) \).

Since \( f_\alpha(\tau) = q^{-p^\alpha m'} + O(1) \), we find that \( U_p f_\alpha(\tau) = q^{-p^{\alpha-1}m'} + O(1) \) has a pole of order \( p^{\alpha-1}m' \) at \( \infty \). So we focus our attention on \( U_p f_\alpha(\tau) - f_{\alpha-1}(\tau) \), which is holomorphic at \( \infty \). Using (2.3) we examine this function at 0:

\[
p(U_p f_\alpha) \left( \frac{-1}{pr} \right) - pf_{\alpha-1} \left( \frac{-1}{pr} \right) = p(U_p f_\alpha)(pr) + f_\alpha \left( \frac{-1}{p^2r} \right) - f_\alpha(\tau) - pf_{\alpha-1} \left( \frac{-1}{pr} \right)
\]

\[
= pq^{-p^\alpha m'} + O(1) + O(1) - q^{-p^\alpha m'} - O(1) - O(1)
\]

\[
= (p-1)q^{-p^\alpha m'} + O(1).
\]

As before, we write this function as a polynomial in \( \psi(\tau) \) with integral coefficients \( c_i \):

\[
p(U_p f_\alpha)(-1/pr) - pf_{\alpha-1}(-1/pr) = c_0 + \sum_{i=1}^{p^\alpha m'} c_i \psi(\tau)^i,
\]
which, after switching back to the $q$-expansion at $\infty$, becomes

\begin{equation}
U_p f_\alpha(\tau) = \frac{c_0}{p} + f_{\alpha-1}(\tau) + \frac{1}{p} \sum_{i=1}^{p\cdot m'} c_i p^{\lambda_i/2} \phi(\tau)^i.
\end{equation}

Notice that (3.3) looks very similar to (3.2), where $\psi(\tau)$ is replaced by $f_{\alpha-1}(\tau)$, so $U_p f_\alpha(\tau)$ inherits whatever divisibility properties $f_{\alpha-1}(\tau)$ has. Our inductive hypothesis states that $f_{\alpha-1}(\tau)$ exhibits Lehner’s divisibility properties only after $U_p$ is applied $\alpha - 1$ times. Therefore, applying $U_p$ to (3.3) $\alpha - 1$ times, we obtain

\begin{equation}
U^\alpha_p f_\alpha(\tau) = \frac{c_0}{p} + U_p^{\alpha-1} f_{\alpha-1}(\tau) + \frac{1}{p} \sum_{i=1}^{p\cdot m'} c_i p^{\lambda_i/2} U_p^{n-1} \phi(\tau)^i
\end{equation}

showing that $U^\alpha_p f_\alpha(\tau)$ exhibits Lehner’s divisibility properties. □
