In the peripheral blood leukocytes (PBLs) from the carriers of the human T-lymphotropic virus type-1 (HTLV-1) or the patients with adult T-cell leukemia (ATL), nuclear factor kappaB (NF-κB)-mediated antiapoptotic signals are constitutively activated primarily by the HTLV-1-encoded oncoprotein Tax. Tax interacts with the IκB kinase regulatory subunit NEMO (NF-κB essential modulator) to activate NF-κB, and this interaction is maintained in part by a molecular chaperone, heat-shock protein 90 (HSP90), and its co-chaperone cell division cycle 37 (CDC37). The antibiotic geldanamycin (GA) inhibits HSP90′s ATP binding for its proper interaction with client proteins. Administration of a novel water-soluble and less toxic GA derivative, 17-dimethylaminoethylamino-17-demethoxygeldanamycin hydrochloride (17-DMAG), to Tax-expressing ATL-transformed cell lines, C8166 and MT4, induced significant degradation of Tax. 17-DMAG also facilitated growth arrest and cellular apoptosis to C8166 and MT4 and other ATL cell lines, although this treatment has no apparent effects on normal PBLs. 17-DMAG also downregulated Tax-mediated intracellular signals including the activation of NF-κB, activator protein 1 or HTLV-1 long terminal repeat in Tax-transfected HEK293 cells. Oral administration of 17-DMAG to ATL model mice xenografted with lymphomatous transgenic Lck-Tax (Lck proximal promoter-driven Tax transgene) cells or HTLV-1-producing tumor cells dramatically attenuated aggressive infiltration into multiple organs, inhibited de novo viral production and improved survival period. These observations identified 17-DMAG as a promising candidate for the prevention of ATL progression.

**INTRODUCTION**

Nuclear factor kappaB (NF-κB) is a transcription factor that regulates immune and antiapoptotic responses to multiple extracellular stresses. Under normal conditions, most NF-κB molecules are sequestered in the cytoplasm by the inhibitor IκB. In response to cellular stress, IκB is rapidly phosphorylated by the NF-κB activator IκB kinase (IKK) and ubiquitylated for degradation by the proteasome. This frees NF-κB for translocation into the nucleus, where it directs the transcriptional activation of NF-κB-responsive genes. IKK is comprised of three different subunits, IKKα, IKKβ and IKKγ/NEMO (NF-κB essential modulator). IKKγ is also known as NF-κB essential modulator (NEMO). NEMO trimerizes rapidly in response to extracellular stimuli, such as the pro-inflammatory cytokine tumor necrosis factor-α (TNF-α), and recruits the two catalytic subunits, IKKα/β, to form a highly phosphorylated active IKK holoenzyme. Several genetic studies have shown that cytokine-triggered activation of what is termed the canonical NF-κB activation pathway is primarily dependent on NEMO and IKKβ, whereas IKKα activity is required for the development of the skin, limbs and lymph nodes. Upon stimulation, several accessory proteins are recruited to IKK, and the molecular size of this active IKK complex reaches more than 1 MDa. The molecular chaperone heat-shock protein 90 (HSP90) and its co-chaperone cell division cycle 37 (CDC37) are components of this high molecular weight (HMW)-IKK complex, and they play crucial roles in maintaining the activity of the complex. The antibiotic geldanamycin (GA) specifically binds to the ATPase domain of HSP90 and inhibits its function as a molecular chaperone, resulting in the efficient inhibition of TNF-α-mediated activation of NF-κB.

The human T-lymphotropic virus type-1 (HTLV-1), which is the etiologic agent of adult T-cell leukemia (ATL), encodes the oncoprotein Tax. Tax activates NF-κB by interacting with the proteasome. This frees NF-κB, and this interaction is maintained in part by a molecular chaperone, heat-shock protein 90 (HSP90), and its co-chaperone cell division cycle 37 (CDC37). The antibiotic geldanamycin (GA) inhibits HSP90′s ATP binding for its proper interaction with client proteins. Administration of a novel water-soluble and less toxic GA derivative, 17-dimethylaminoethylamino-17-demethoxygeldanamycin hydrochloride (17-DMAG), to Tax-expressing ATL-transformed cell lines, C8166 and MT4, induced significant degradation of Tax. 17-DMAG also facilitated growth arrest and cellular apoptosis to C8166 and MT4 and other ATL cell lines, although this treatment has no apparent effects on normal PBLs. 17-DMAG also downregulated Tax-mediated intracellular signals including the activation of NF-κB, activator protein 1 or HTLV-1 long terminal repeat in Tax-transfected HEK293 cells. Oral administration of 17-DMAG to ATL model mice xenografted with lymphomatous transgenic Lck-Tax (Lck proximal promoter-driven Tax transgene) cells or HTLV-1-producing tumor cells dramatically attenuated aggressive infiltration into multiple organs, inhibited de novo viral production and improved survival period. These observations identified 17-DMAG as a promising candidate for the prevention of ATL progression.

**INTRODUCTION**

Nuclear factor kappaB (NF-κB) is a transcription factor that regulates immune and antiapoptotic responses to multiple extracellular stresses. Under normal conditions, most NF-κB molecules are sequestered in the cytoplasm by the inhibitor IκB. In response to cellular stress, IκB is rapidly phosphorylated by the NF-κB activator IκB kinase (IKK) and ubiquitylated for degradation by the proteasome. This frees NF-κB for translocation into the nucleus, where it directs the transcriptional activation of NF-κB-responsive genes. IKK is comprised of three different subunits, IKKα, IKKβ and IKKγ/NEMO (NF-κB essential modulator). IKKγ is also known as NF-κB essential modulator (NEMO). NEMO trimerizes rapidly in response to extracellular stimuli, such as the pro-inflammatory cytokine tumor necrosis factor-α (TNF-α), and recruits the two catalytic subunits, IKKα/β, to form a highly phosphorylated active IKK holoenzyme. Several genetic studies have shown that cytokine-triggered activation of what is termed the canonical NF-κB activation pathway is primarily dependent on NEMO and IKKβ, whereas IKKα activity is required for the development of the skin, limbs and lymph nodes. Upon stimulation, several accessory proteins are recruited to IKK, and the molecular size of this active IKK complex reaches more than 1 MDa. The molecular chaperone heat-shock protein 90 (HSP90) and its co-chaperone cell division cycle 37 (CDC37) are components of this high molecular weight (HMW)-IKK complex, and they play crucial roles in maintaining the activity of the complex. The antibiotic geldanamycin (GA) specifically binds to the ATPase domain of HSP90 and inhibits its function as a molecular chaperone, resulting in the efficient inhibition of TNF-α-mediated activation of NF-κB.

The human T-lymphotropic virus type-1 (HTLV-1), which is the etiologic agent of adult T-cell leukemia (ATL), encodes the oncoprotein Tax. Tax activates NF-κB by interacting
physically with NEMO.10,17 NF-κB activation mediated by this Tax–NEMO interaction is similar to that of the TNF-α-triggered ‘canonical’ pathway. Tax induces IKK phosphorylation, ubiquitylation and proteasome-dependent degradation of IκB, thereby inducing the translocation of NF-κB into the nucleus.18,19 However, in contrast to the TNF-α-triggered canonical pathway, which is transient and mostly IKKβ dependent, Tax-mediated NF-κB activation is persistent and utilizes both the IKKα and IKKβ subunits.20,21 From these observations, we speculated that oncogenic Tax-mediated activation of NF-κB is distinguishable from the canonical NF-κB activation pathway, and indeed, we have succeeded in inhibiting Tax-mediated NF-κB activation using selected sets of NEMO-mutant peptides.11

Those earlier studies led us to ask whether GA can inhibit Tax-mediated HMW-IKK formation and suppress NF-κB activation as has been demonstrated in the TNF-α-triggered canonical pathway. To address this, we treated ATL cell lines or HEK293 cells transfected with a Tax expression vector with GA or its less toxic derivative 17-dimethylaminoethylamino-17-demethoxygeldanamycin hydrochloride (17-DMAG).22 We found that these HSP90 inhibitors downregulated Tax-mediated intracellular activity including the activation of NF-κB, activator protein 1 and HTLV-1 long terminal repeat (HTLV-1-LTR). These findings prompted us to investigate the molecular mechanisms by which HSP90 inhibitors disrupt Tax-mediated signaling in ATL cells. We found that the stability of Tax in ATL cells is heavily dependent on the HSP90/CDC37 chaperones and that Tax is rapidly degraded without these chaperones following the addition of HSP90 inhibitors. Apoptosis of ATL cells was also induced by GA and 17-DMAG. Finally, the oral administration of 17-DMAG to severe combined immunodeficient (SCID) mice transplanted with lymphomatous cells bearing Lck proximal promoter-driven Tax transgene (Lck-Tax) cells23 markedly inhibited the aggressive infiltration of these Lck-Tax cells into multiple organs. The same procedure to the humanized NOG (huNOG) mice inoculated with HTLV-1-producing Jurkat cells also resulted in the suppression of de novo viral production and improved the survival period.

MATERIALS AND METHODS

Ethics statement
This study was carried out in strict accordance with the recommendations in the Guidelines for Proper Conduct of Animal Experiments, Science Council of Japan (http://www.scj.go.jp/en/animal/index.html). All procedures involving animals and their care were approved by the Animal Care Committee of Oita University, National Institute of Infectious Diseases and Kansai Medical University in accordance with the Regulations for Animal Experiments in Oita University (approval ID: 24-22).

Chemicals, cells and cell culture conditions
All chemicals used in this study including 17-DMAG22 and cell lines or peripheral blood leukocytes (PBLs) were described in Supplementary Information.

Coimmunoprecipitation and immunoblot
One million cells of MT4 and C8166 treated with or without 17-DMAG and HEK293 cells transfected with each plasmid (maximum 1 μg) by FugeneHD (Roche Applied Science, Tokyo, Japan) for 40 h were lysed with coimmunoprecipitation (Co-IP) buffer. Each 200 μg of precleared (with 30 μl of protein G agarose, CalBiochem, Millipore Corporation, Billerica, MA, USA) lysates was incubated with 2 μg of rabbit polyclonal anti-HSP90 (Stressgen Bioreagents, Ann Arbor, MI, USA) or rabbit anti-FLAG antibody (Sigma-Aldrich, St Louis, MO, USA) for at least 3 h at 4 °C. Antibody–protein G complexes were washed, resolved by sodium dodecyl sulfate-polyacrylamide gel electrophoresis and transferred onto a polyvinylidene difluoride membrane, and specific proteins were detected by monoclonal anti-Tax, -HSP90 (Stressgen), -Flag, -tubulin (Sigma) or polyclonal anti-IκKα (Cell Signaling Technology) antibodies, respectively.

Real-time quantitative reverse transcriptase-PCR by the LightCycler system
Total RNA from MT4 cells treated with or without 17-DMAG was isolated using ISOGEN (Wako Pure Chemical Industries, Ltd., Osaka, Japan), and contaminated DNA was removed. cDNA was constructed by the Thermoscript reverse transcriptase-PCR system (Invitrogen, Life Technologies Japan Co., Tokyo, Japan), and real-time quantitative PCRs for Tax and glucose-6-phosphate 1-dehydrogenase were performed on a Roche LC480 system (Roche) with indicated probe and primer sets.

Cell viability assay
Cell lines or PBLs from ATL patients or healthy donors were treated with 2.5 μM of 17-DMAG for 1–4 days. After every 24 h incubation, cell viabilities were counted with Cell Counting Kit (Dojindo Laboratories, Kumamoto, Japan).

Caspase-3/7 assay
Cells used in the ‘cell viability assay’ were also subjected for apoptosis activity with caspase-3/7 assay and GLOMAX 96 microplate luminometer (Promega KK, Tokyo, Japan).

Plasmids
The details of plasmid pSG5-Tax,24 HSP90,25 Cdc37,26 CMV-Tax or LTR-Tax11 and CoralHuTax or – Cdc37 vectors (MBL Co. Ltd., Nagoya, Japan)27 are described in Supplementary Information.

Luciferase assay
HEK293 cells were transfected with plasmid DNA mixture containing the reporter plasmids (NF-κB-Luc or HTLV-1-LTR-Luc11 and RSV-β-galactosidase as a transfection indicator) and Tax expression vectors (pSG5-Tax, CMV-Tax or LTR-Tax) by FugeneHD. After 24 h incubation of the transfection, where indicated, 17-DMAG at concentrations listed in the figures was added, and cells were further incubated for 16 h. Cell lysates were subjected to the luciferase assay kit and GLOMAX 96.

Microscopic observation of cells
HEK293 cells were transfected with phmKGN-MC-Tax and phmKGC-MN-Cdc37 or its mutant – Cdc37(N200) or – Cdc37(N180) for 48 h and then treated with 1 μM of Hoechst 34442 (Sigma). Light and fluorescent (green fluorescent protein (GFP) or Hoechst 34442) microscopic observation and photography were performed by BX-9000 BioRevo (Keyence Co. Ltd, Osaka, Japan).

Transfer of Lck-Tax transgenic cells to SCID mice and treatment with 17-DMAG
SCID mice were injected intraperitoneally with 2 × 106 Lck-Tax cells.23 17-DMAG was administered orally 5 days per week with 5, 15 or 30 mg/kg for 2–3 weeks, and then mice were sacrificed for pathological examination.

HTLV-1 infection to huNOG and flow cytometric analysis of peripheral bloods
Suspension of irradiated 1 × 108 HTLV-1-producing JEX cells was inoculated intraperitoneally into huNOG mice28 at the age between 24 and 28 weeks. Peripheral blood cells were routinely collected every 2 weeks after infection. Spleen, bone marrow and lymph node were collected, and PBLs were stained with florescent dye-conjugated antibodies against human cellular surface markers.

DNA isolation and quantification of proviral load
Genomic DNA was extracted from single cell suspension of tissue or peripheral blood followed by the conventional phenol extraction method. Proviral load was measured by quantitative PCR as previously described.29

Histopathological examination and immunohistochemistry
Tissues were directly fixed in the neutral buffered formalin (Sigma), embedded in paraffin, sectioned and stained with hematoxylin and eosin. Peripheral blood smears were prepared using Giemsa staining and examined by light microscopy.

For details, see Supplementary Information.
RESULTS
The NF-κB-activating Tax–HSP90–IKK ternary complex is disaggregated by HSP90 inhibitors that induce Tax degradation. The molecular chaperone HSP90 and its co-chaperone CDC37 are both recruited to IKK and play essential roles in TNF-α-activated HMW-IKK formation and subsequent NF-κB activation. The addition of the HSP90-specific inhibitor GA completely suppresses NF-κB signaling. As we previously demonstrated, the expression of another NF-κB inhibitor dexamethasone had no effects (Supplementary Figure 1). Tax degradation by 17-DMAG occurred prior to mRNA suppression as the marked decrease of Tax mRNA was not observed until 24 h after treatment (Figure 1d), whereas protein level of Tax was obviously decreased by 12 h (compare Figures 1c and d). Our previous study indicated that Tax degradation is partly induced by caspase, and polyubiquitylation had little effects on its cellular stability. Therefore re-evaluated which pathway is responsible for the 17-DMAG-induced Tax degradation (Figure 1e); Tax degradation was partly blocked by the caspase inhibitor zVAD-fmk and by autophagy inhibitors 3-methyladenine (3-MA) and 5-aminoimidazole-4-carboxamide-1-b-D-ribofuranoside (AICAR) but not by the proteasome inhibitor MG132. Similar findings were obtained from parallel studies using another ATL cell line, C8166 (data not shown), although more investigation is needed for fully understanding of Tax instability.

GA and its derivatives are known to suppress a variety of intracellular signaling pathways, including NF-κB activation by inhibiting IKK. One of the most important functions of NF-κB is to protect cells from apoptotic stress. A portion of 2.5 μM of 17-DMAG is sufficient to induce Tax degradation (Figure 1c) and NF-κB stabilization (Supplementary Figure 1), which implies the suppression of ATL cell growth; however, it is important to know whether this concentration is toxic to normal PBLs. We, therefore, confirmed the median inhibitory concentrations of 17-DMAG for several ATL or non-ATL cell lines along with normal PBLs.

Figure 1. 17-DMAG inhibits HSP90–Tax–IKK ternary complex formation and induces Tax degradation in ATL cells. (a) Co-IP of Tax and HSP90. Four million Jurkat or MT4 cells were lysed with Co-IP buffer, and 50 μg total cell lysates were subjected to IP with 2 μg of rabbit polyclonal anti-HSP90 antibody, followed by immunoblot (IB) with mouse monoclonal anti-Tax antibody (upper panel). The amount of expressed Tax in each cell line was verified by IB with anti-Tax against 10 μg of cell lysates (lower panel). (b) 17-DMAG's effects on Tax expression level and physical interaction between HSP90 and IKKβ in MT4 cells. Four million MT4 cells were treated with the indicated concentrations of 17-DMAG for 16 h. Co-IP and IB against immunoprecipitates or lysates were carried out as in panel a. (c) Ten micrograms of each cell lysate from MT4 cells treated with or without 2.5 μM of 17-DMAG for the indicated periods were subjected to sodium dodecyl sulfate-polyacrylamide gel electrophoresis, and Tax (upper panel), HSP90 (middle panel) or tubulin (lower panel) expression was detected using monoclonal anti-Tax, anti-HSP90 or anti-tubulin antibodies. (d) Expression levels of Tax in 17-DMAG-treated MT4 cells. mRNAs were prepared from the same aliquots of MT4 cells described in panel c. mRNAs from 17-DMAG-untreated fractions (black bars) and 17-DMAG-treated fractions (2.5 μM, white bars) with indicated time courses were analyzed with the universal probes (Roche) and primers through the LightCycler PCR method according to the manufacturer's direction. Comparison of Tax mRNAs with or without 17-DMAG was also indicated with a red line graph as a division of Tax mRNA with 17-DMAG/without 17-DMAG at each time point. (e) Four million MT4 cells were treated with 2.5 μM of 17-DMAG for 24 h (lanes 2–6) and then additional 3 μM MG132 for 12 h (lane 3), 10 μM of zVAD-fmk (lane 4) and 3-MA (lane 5) and 1 μM AICAR (lane 6) for 24 h. Lysates were prepared for IB of Tax and tubulin.
The median inhibitory concentrations to ATL cells vary from 0.06 to 2.33 \( \mu M \), which is much lower than that of non-ATL Jurkat cells (9.32 \( \mu M \)), and three PBLs did not show any significant growth suppression with 10 \( \mu M \) of 17-DMAG (Supplementary Figure 2). We set the concentration of 17-DMAG at 2.5 \( \mu M \) and measured the effects on the viability of ATL cells (cell lines established from ATL patients’ PBLs or cord blood cocultured with ATL patients’ PBLs or primary PBLs of ATL patients) and other leukemic cells, as well as PBLs from HTLV-1-negative controls. Most of the ATL cell lines treated with 17-DMAG exhibited a rapid decrease in viability, whereas normal PBLs were unaffected by the drug (Figure 2a). 17-DMAG treatment also resulted in a marked increase in caspase-3/7 activity in most of the ATL cell lines while having no significant caspase perturbation in control PBLs (Figure 2b).

Downregulation of Tax occurs at the post-transcriptional stage

We then proceeded to examine the details of 17-DMAG-dependent inhibitory effects on the Tax–HSP90–IKK ternary complex by transfection of two different Tax expression vectors into HEK293 cells. One was driven by the simian virus 40 early promoter and the other by the RSV LTR promoter. Figure 3 shows the results of these experiments. The expression levels of Tax, HSP90, and tubulin in 10 \( \mu g \) of lysates from panel (a) were monitored by IB with monoclonal antibodies for each protein.

Figure 2. 17-DMAG induces growth arrest and apoptosis in ATL cells. Two million cells from each ATL cell line established from ATL patients’ PBLs (HUT-102, ED, S1T, SU9T, ATL4 and ATL9; red lines), ATL cell lines established by coculture of cord blood and ATL patients’ PBLs (C8166 and MT4; orange lines), PBLs from ATL patients (Pat1 to Pat4; purple lines), non-ATL leukemic cell lines (Jurkat, HL-60, MOLT-4 and HUT-78; yellow lines) or healthy donors (PBL1, PBL2 and PBL3; blue lines) were treated with 2.5 \( \mu M \) of 17-DMAG for 1–4 days. After each 24 h incubation, 10 \( ^4 \) (a) or 5 \( \times 10^3 \) (b) cells were transferred to each well of a 96-well plate. (a) One-tenth volume of Cell Counting Kit-8 solution (Dojindo) was added to each fraction. Thirty minutes after incubation, the absorbance at 465 nm was measured using an E-max precision microplate reader (Molecular Devices Japan Co. Ltd., Tokyo, Japan). (b) The same volume of Apo-ONE homogeneous Caspase-3/7 assay solution was added to cells, and chemical luminescence was quantified with GloMax luminometer (Promega).

Figure 3. 17-DMAG downregulates all the Tax-mediated signaling in HEK293 cells. Fifty thousand HEK293 cells in each well on a 12-well plate were transfected with 0.5 \( \mu g \) of pSG-Tax (a, c) or pLTR-Tax along with 50 ng of NF-\( \kappa \)B-luciferase (a, c) or HTLV-1-LTR-luciferase (d) and 50 ng of RSV-\( \beta \)-galactosidase control plasmid. A portion of 0.1–5 \( \mu M \) of 17-DMAG was added as indicated for 16 h. (b) The expression levels of Tax, HSP90 and tubulin in 10 \( \mu g \) of lysates from panel (a) were monitored by IB with monoclonal antibodies for each protein.
β-globin intron II (pSG5-Tax), whereas the other was driven by the HTLV-1-LTR (LTR-Tax). These lines were transfected with either a NF-κB-responsive or a HTLV-1-LTR luciferase reporter (Figures 3a and b and Figures 3c and d, respectively) and RSV-β-galactosidase for readout normalization. 17-DMAG treatment was found to suppress Tax-mediated NF-κB (Figures 3a, b and c) or HTLV-1-LTR activation (Figure 3d) regardless of whether Tax was expressed from pSG5-Tax (Figures 3a and b) or LTR-Tax (Figures 3c and d). In these experiments, the ectopically expressed Tax from transfected plasmid was again downregulated by 17-DMAG (Figure 3b). The same results were also obtained from the cell lysates transfected with LTR-Tax or CMV-Tax (data not shown). In addition to these two enhancers, activator protein 1 activation by Tax was also inhibited by 17-DMAG (data not shown). As the three discrete pathways

Figure 4. CBD of Cdc37 plays a crucial role for Tax stability in cells. (a) Co-transfection of LTR-Tax and pcDNA3-Flag-tagged Cdc37 (F-Cdc37) mutants. Lane 1: control pcDNA3 1 μg; lane 2: LTR-Tax 0.5 μg + pcDNA3 0.5 μg; lane 3: LTR-Tax 0.5 μg + F-Cdc37(1–378) wild type 0.5 μg; lane 4: LTR-Tax 0.5 μg + F-Cdc37(1–200) 0.5 μg; lane 5: LTR-Tax 0.5 μg + F-Cdc37(1–180) 0.5 μg; lane 6: LTR-Tax 0.5 μg + F-Cdc37(181–378) 0.5 μg; lane 7: LTR-Tax 0.5 μg + F-Cdc37(201–378) 0.5 μg. After 40 h transfection, HEK293 cells were lysed with 100 μl of lysis buffer, and the NF-κB-dependent luciferase activity was normalized with β-galactosidase value (upper panel). A portion of 10 μg of each lane’s cell lysates was mixed and subjected to Co-IP with 2 μg of rabbit anti-Flag antibodies, and each Co-IP complex was washed four times with Co-IP buffer, and following sodium dodecyl sulfate-polyacrylamide gel electrophoresis, Tax was detected by anti-Tax antibody (upper panel), Flag-tagged Cdc37s (middle panel) and tubulin (lower panel) were detected by specific monoclonal antibodies. (b) Dose-dependent degradation of Tax by F-Cdc37 mutants. Lane 1: control pcDNA3 1 μg; lanes 2–11: 0.5 μg of LTR-Tax; lanes 3–5: plus 0.125, 0.25 and 0.5 μg of F-Cdc37(1–200); lanes 6–8: plus 0.125, 0.25 and 0.5 μg of F-Cdc37(1–180); lanes 9–11: plus 0.125, 0.25 and 0.5 μg of F-Cdc37(181–378). pcDNA3 was added to normalize the DNA amount. Tax (upper panel), Flag-tagged Cdc37s (middle panel) and tubulin (lower panel) were detected by specific monoclonal antibodies. (c) Cdc37’s CBD (amino-acid residues 181–200(ref. 26)) is required for Tax interaction. A portion of 0.5 μg of control pcDNA3 (lane 1) or LTR-Tax (lanes 2–9) was transfected (lyseate-1, middle panel) and 0.5 μg of control pcDNA3 (lanes 1 and 2), F-HSP90 (lane 3), wild-type F-Cdc37(1–378, lane 4), F-Cdc37(1–278, lane 5), F-Cdc37(1–200, lane 6), F-Cdc37(1–180, lane 7), F-Cdc37(181–378, lane 8) and F-Cdc37(201–378, lane 9) were transfected separately (lyseate-2, lower panel). The expression of each protein in cell lysates was detected by specific monoclonal antibodies (middle and bottom panels). A portion of 200 μg of each lane’s cell lysates was mixed and subjected to Co-IP with 2 μg of rabbit anti-Flag antibodies, and each Co-IP complex was washed four times with Co-IP buffer, and following sodium dodecyl sulfate-polyacrylamide gel electrophoresis, Tax was detected by anti-Tax antibody (upper panel). (d) GFP two-hybrid binding assay between Cdc37 and Tax. HEK293 cells seeded on the six-well plates were transfected with phmKGN-MC-Tax and phmKGC-MN-Cdc37 or its mutant — Cdc37(N200) and — Cdc37(N180) by FugeneHD. After 48 h incubation, the transfected HEK293 cells were treated with Hoechst 34442 (Sigma) at the final concentration of 1 μl. Light and fluorescent (GFP and Hoechst 34442) microscopic observation and photography were performed by BZ-9000 Bioeve all-in-one fluorescence microscope (Keyence).
activated by Tax are inhibited by 17-DMAG treatment, the simplest interpretation suggests that all these effects arise from 17-DMAG-mediated destabilization of the Tax protein itself.

The client-binding domain of CDC37 plays crucial roles in Tax stabilization and Tax-mediated NF-κB activation.

The molecular chaperone activity of HSP90 is usually exerted in cooperation with various co-chaperones. CDC37 was identified along with HSP90 as an essential component for a TNF-α-activated HMW-IKK complex. As our current study shows the involvement of HSP90 in Tax-mediated HMW-IKK formation and NF-κB activation, we generated Flag-tagged serial deletion mutants of HSP90 and CDC37 to examine their potential effects on Tax activity.

HSP90 has three distinct functional domains as described in Supplementary Figure 3. We generated five deletion mutants, N, N + M, M, M + C and C, and transduced each with a Tax expression vector into HEK293 cells to determine any dominant-negative effects. Surprisingly, none of these mutants showed suppressive effects on Tax-mediated NF-κB activation or Tax stabilization (data not shown).

We then investigated the possible involvement of CDC37 in Tax stabilization and NF-κB signaling according to its functional domains (Supplementary Figure 3), namely, an HSP90-binding domain expanding through M164 to E221, a kinase-binding domain at amino-acid residues 40–110, a client-binding domain (CBD, amino-acid residues 181–200) and a self-dimerization domain (amino-acid residues 240–260). Although overexpression of full-length CDC37 slightly enhanced NF-κB activation, the mutants containing CBD, CDC37(1–200) and CDC37(181–378), strongly suppressed Tax-mediated NF-κB activation and induced extensive Tax degradation (Figure 4a middle panel, lanes 4 and 6). The mutants CDC37(1–180) and CDC37(201–378) lacking CBD had little effects on either NF-κB activation or Tax stability (lanes 5 and 7). Tax degradation was reconfirmed by titration of these mutants (Figure 4b). Both CCD37(1–200) and CCD37(181–378) progressively promoted Tax degradation (lanes 3–5 and 9–11, respectively), but CDC37(1–180) had little effects (lanes 6–8). Coexpression of certain sets of CDC37 mutants could promote Tax degradation through impaired physical interaction with Tax. We transfected HEK293 cells with Tax or Flag-CDC37 expression vectors separately to avoid spontaneous Tax degradation, and each cell lysate was mixed and applied for Co-IP experiments with anti-Flag antibodies. Each protein expression was confirmed by immunoblotting for Tax (middle panel) or Flag (lower panel). Although the immunoprecipitates from wild-type HSP90 (upper panel, lane 3), CDC37 (lane 4) and Tax-degrading CDC37(1–200) and CDC37(1–378) (lanes 6 and 8) contained Tax in the complex, the immunoprecipitates from CDC37(1–180) and CDC37(201–378) lacking Tax-degrading properties did not (lanes 7 and 9).

Finally, we examined direct interaction between the two proteins using a GFP two-hybrid assay. Tax, tagged with the N-terminal portion of Kusabira-Green fluorescent protein, and CDC37s (1–378, 1–200 and 1–180), tagged with the C-terminal portion, were co-transfected into HEK293 cells. Consistent with Co-IP results, co-transfectants of Tax and CDC37(1–378) or CDC37(1–200) emitted green fluorescence but Tax plus CDC37(1–180) or CDC37(201–378) did not.

Figure 5. Oral administration of 17-DMAG blocks aggressive infiltration of Lck-Tax Tg cells into multiple organs of SCID mice. Two million Lck-Tax Tg cells were injected intraperitoneally into SCID mice. 17-DMAG was administered orally 5 days per week, with 5 mg/kg body weight (e–h) or 15 mg/kg body weight (i–l) or untreated (a–d). Mice were sacrificed after 21 days incubation, and organs were processed for Giemsa (a, e, i) or hematoxylin and eosin (HE, b–d, f–h and j–l) staining. Microscopic observations were performed and photographed with indicated magnifications. Tg, transgenic.
(1–180) did not. The Tax–CDC37(1–200) complex was translocated to the cytoplasm (Figure 4d). Collectively, these findings suggested the direct involvement of CDC37 for Tax stabilization.

An oral administration of 17-DMAG to ATL model mice induced blockade of aggressive proliferation and multiple tissue invasions of transformed lymphocytes and improved survival rate. The demonstration that 17-DMAG has profound effects on Tax stability and the fact that it is water soluble suggested that this compound could be tested in a recently developed preclinical model of ATL.23,28

SCID mice were injected with $2 \times 10^6$ Lck-Tax cells intra-peritoneally and treated for 5 consecutive days per week for 2 weeks with saline alone or with 17-DMAG in saline at 5 or 15 mg/kg. Mice were euthanized 21 days after cell inoculation. The blood smear indicated apparent reduction of Lck-Tax cells with increasing doses of 17-DMAG to saline controls (Figures 5a, e and i), although the quantitative cell counts were not obtained. The white pulp in greatly enlarged spleens (splenomegaly) of control mice was markedly expanded with red pulp compression (Figure 5b), and the livers and lungs of saline control mice were characterized by extensive perivascular infiltrations with Lck-Tax cells (Figures 5c and d). These pathologies were progressively reduced in mice treated with 17-DMAG (spleen, Figures 5f and j; liver, Figures 5g and k; and lung, Figures 5h and l).

We then determined the survival improvement through 17-DMAG oral administration with another preclinical ATL model (Figure 6). Each 7 (14 in total) huNOG mice were injected with $1 \times 10^6$ HTLV-1-producing JEX cells (details are described in Supplementary Information), and 2 weeks after inoculation, each 4 of these mice (8 in total) were treated 20 times with 15 or 25 mg/kg of 17-DMAG for 4 weeks (as shown in Supplementary Figure 4), whereas the remaining 6 mice received saline only. The percentage of CD25-positive T cells, proviral load and the number of human leukocytes in peripheral blood were monitored. Four of eight 17-DMAG-treated mice died within 8 weeks post inoculation probably because of high drug dosage, but other four mice (50%) survived more than 20 weeks, whereas all the saline-treated controls died within 12 weeks post inoculation. The average survival period of controls and 17-DMAG-treated subjects were 8.33 and 14.75 weeks, respectively. However, the survival periods of 17-DMAG-treated subjects could be extended because four subjects were sacrificed at 24 weeks post inoculation for pathological examination (Supplementary Figure 4). The numbers of HTLV-1-infected human leukocytes in peripheral blood of 17-DMAG-treated subjects were also 5–10 times fewer than those of saline controls (Figures 6b and c).

Additive effects for growth arrest and apoptosis induction by concomitant 17-DMAG/Nutlin-3a treatment against ATL cells

The standard chemotherapy against ATL, named as leukemia study group 15 (LSG15), is currently employing the combination of four different anticancer drugs that frequently brings serious side effects to patients.10 We previously demonstrated that a novel MDM-2-antagonizing/p53-stabilizing drug, Nutlin-3a, induces...
the senescent death to ATL cells. We then examined the additive anti-ATL effects of 17-DMAG and Nutlin-3a. Suboptimal dose of 17-DMAG (0.1 μM) or Nutlin-3a (1 μM) alone did not induce sufficient apoptotic or growth-arrest activities to ATL cell lines. However, the combined use of both induced significant growth suppressive and apoptotic properties (Figure 7), suggesting the possible combinational use of these drugs for further clinical studies.

DISCUSSION

HTLV-1 is the etiologic agent of ATL. Current studies indicate that worldwide there are more than 20 million HTLV-1 carriers and that 5% of these carriers will develop ATL. The current standard for treatment of acute- or lymphoma-type ATL in Japan is CHOP or its modified regimen LSG15; however, the responses to this treatment regimen are limited to 31.1% of patients with 2-year survivals. As malignant cells from relapsed patients are also resistant to other chemotherapeutic interventions, novel strategies for treatment of ATL are urgently required.

In this study, we demonstrated the significant inhibitory effects of 17-DMAG on Tax-mediated NF-κB signaling in vitro and ex vivo. The most striking observations obtained in vitro were (a) 17-DMAG-induced Tax degradation that resulted from inhibiting the formation of the Tax–IKK–HSP90/CDC37 ternary complex (Figures 1a–d); (b) induction of growth suppression and apoptosis of ATL cells while having little or no effect on normal PBLs (Figures 1a–d). We also found that the stability of Tax was heavily dependent on the CBD of CDC37 (Figures 4a and b).

GA-dependent NF-κB downregulation in ATL cells was reported, and inhibition of autophagic activity seemed to affect the conversion of p100 (NF-κB2 precursor) to active p52. We observed this time 17-DMAG-dependent Tax degradation and its blockade by AICAR and 3-MA (autophagy inhibitors) but not by the proteasome inhibitor MG-132 (Figure 1d), suggesting the direct involvement of the autophagosome on Tax metabolism in cells. This issue should further be investigated with ubiquitylation-deficient mutants Tax or the autophagy-deficient cells.

The CBD of CDC37 has been reported to bind preferentially to a specific glycine-rich motif — GXGXXG. Indeed, Tax has a similar motif in its N terminus. CBD played crucial roles in stabilizing Tax and Tax–CDC37 complex formation (Figures 4c and d). CDC37 containing mutants of CDC37 seemed to enhance the machinery responsible for Tax degradation as we did not detect any decrease in Tax levels in response to an siRNA knockdown of CDC37 (Supplementary Figure 5). Interestingly, the Tax destabilizing CDC37(N200) translocated Tax to the nucleus, whereas wild-type CDC37 stayed with Tax in the cytoplasm (Figure 4d), and it implies that this translocation could be related to the Tax destabilization. For the future, it would be worth trying to identify a chemical compound that mimics the structure of CBD and could function as an inducer of Tax degradation. HSP90 and its co-chaperone involvement in multiple signaling cascades, especially, in cancer cells, has been reported.

Indeed, 17-DMAG also suppressed NF-κB signaling mediated by other activators NIK, MEKK1, AKT, TAB2 and IKKα/β (data not shown). We also found that 17-DMAG treatment induced Tax degradation; potentially 17-DMAG treatment may also have led to the destabilization of other NF-κB signaling activators.
We have determined the therapeutic effects of 17-DMAG on two different ATL model systems through its oral administration. First, we tested 17-DMAG induced prevention of Lck-Tax infiltration in SCID mice, and 5 and 15 mg/kg of oral administration of 17-DMAG for 2 weeks reduced 74% and 83% of Lck-Tax cells, respectively; splenomegaly or massive infiltration of Lck-Tax cells into livers and lungs was also significantly reduced (Figure 5). In all experiments, 17-DMAG mice did not show any body weight losses or inactiveness compared with saline controls.

We then switched to another ATL model experiment JEX/huNOG, which has humanized immune environment in NOG mice and has inoculated HTLV-1-producing Jurkat cells. With oral administration of both 15 and 25 mg/kg 17-DMAG to JEX/huNOG, four of eight mice survived more than 20 weeks, whereas saline controls died within 12 weeks (Figure 6a). 17-DMAG treatment also reduced the number of HTLV-1-infected cells in peripheral blood, suggesting that 17-DMAG treatment could intervene the clonal T-cell development to ATL (Figure 6b). Although this preliminary experiment did not provide statistically significant survival rates, efficacy of this treatment is indeed highly expected. It is necessary to find the optimized conditions suppressing the ATL cell proliferation without any serious side effects.

Tax has pleiotropic effects on intra-cellular or inter-cellular signalings including mitotic checkpoint disruption,49 aberrant cell-cycle progression50,51 and altered chemotaxis.51 The present ATL treatment protocols target the cytoskeletons or DNA replication with multiple doses of anticancer drugs (called as LSG15), and significant side effects by this treatment have been frequently recognized.40 We have recently demonstrated the potential use of molecularly targeted inhibitors of ATL cell proliferation, such as a MDM-2 ubiquitin ligase inhibitor Nutlin-3a41 or CXCR4 antagonist AMD3100.51 Nutlin-3a induces growth arrest and senescent-cell death of ATL cells at the 10 μM concentration, but normal PBLs are also significantly affected.48 The combined use of 17-DMAG (0.1 μM) and Nutlin-3a (1 μM), suboptimal concentration for single use, significantly enhanced both apoptotic and growth suppressive effects (Figures 7a and b). This concurrent effects can be manifested with the division of caspase-3/7 values by Cell Death Differ (Figure 7c). Besides Nutlin-3a, we also tested the efficacy of 17-DMAG plus LSG15 (without preonisolone; Supplementary Figure 6). Unlike the results of 17-DMAG/Nutlin-3a, 17-DMAG/LSG15 did not show any clear additive effects probably because LSG15 affects cell-cycle progression with a wide range of spectrum, but the effects of Nutlin-3a are specifically restricted to p53 stabilization.

It remains to be seen whether 17-DMAG is effective for ATL patients’ treatment; elsewhere Hertlein et al.52 have reported 17-DMAG’s clinical application against chronic lymphocytic leukemia. Perhaps in future studies, 17-DMAG and other new drugs with novel anti-ATL activities such as Nutlin-3a, AMD3100 or leukemia. Perhaps in future studies, 17-DMAG and other new drugs with novel anti-ATL activities such as Nutlin-3a, AMD3100 or

---

**AUTHOR CONTRIBUTIONS**

HI, J-F and HI designed the research; HDH, HS, WWH, KT, TU and J-F developed the ATL animal model; EL, AK, KT, ST, SH, TMA, TU, TMI, KS, J-F and HI performed the research; AN, MH, HH, YY, YT, HS, WH, YM, KTJ, MO and KM contributed new reagents/materials; AK, KT, J-F and HDH contributed pathologic analysis; and EL KT, J-F, HDH and HI wrote the paper.
